12.11 | Ethanol, with $\Delta H_{\text{vap}} = 40.5$ kJ mol^{-1}, has a higher ΔH_{vap} than methanol, which was calculated in Example 12.3 as 35.2 kJ mol^{-1}, due to its larger size and greater intermolecular forces. Because the ΔH_{vap} for ethanol is larger, we would expect that for the two liquids to reach the same vapor pressure, the temperature for ethanol would have to be higher. If the vapor pressure is 0.0992 atm at 27.3 °C, what would the temperature be when the vapor pressure is 1.00 atm?

12.9 | Le Châtelier's Principle and State Changes

Throughout this chapter, we have studied various dynamic equilibria. One example was the equilibrium that exists between a liquid and its vapor in a closed container. You learned that when the temperature of the liquid is increased in this system, its vapor pressure also increases. Let's briefly review why this occurs.

Initially, the liquid is in equilibrium with its vapor, which exerts a certain pressure. When the temperature is increased, equilibrium no longer exists because evaporation occurs more rapidly than condensation. Eventually, as the concentration of molecules in the vapor increases, *the system reaches a new equilibrium* in which there is more vapor and a little less liquid. The greater concentration of molecules in the vapor causes a larger pressure.

The way a liquid's equilibrium vapor pressure responds to a temperature change is an example of a general phenomenon. *Whenever a dynamic equilibrium is upset by some disturbance, the system changes in a way that will, if possible, bring the system back to equilibrium again.* It's also important to understand that in the process of regaining equilibrium, the system undergoes a net change. Thus, when the temperature of a liquid is raised, there is some net conversion of liquid into vapor as the system returns to equilibrium. When the new equilibrium is reached, the amounts of liquid and vapor are not the same as they were before.

Throughout the remainder of this book, we will deal with many kinds of equilibria, both chemical and physical. It would be very time consuming and sometimes very difficult to carry out a detailed analysis each time we wish to know the effects of some disturbance on an equilibrium system. Fortunately, there is a relatively simple and fast method for predicting the effect of a disturbance, one based on a principle proposed in 1888 by a brilliant French chemist, Henry Le Châtelier (1850–1936).

Le Châtelier's Principle
When a dynamic equilibrium in a system is upset by a disturbance, the system responds in a *direction* that tends to counteract the disturbance and, if possible, restore equilibrium.

TOOLS
Le Châtelier's principle

Let's see how we can apply Le Châtelier's principle to a liquid–vapor equilibrium that is subjected to a temperature increase. We cannot increase a temperature, of course, without adding heat. Thus, *the addition of heat is really the disturbing influence when a temperature is increased.* So, let's incorporate "heat" as a member of the equation used to represent the liquid–vapor equilibrium.

$$\text{heat} + \text{liquid} \rightleftharpoons \text{vapor} \qquad \textbf{(12.4)}$$

Recall that we use double arrows, $\rightleftharpoons$, to indicate a dynamic equilibrium in an equation. They imply opposing changes happening at equal rates. Evaporation is endothermic, so the heat is placed on the left side of Equation 12.4 to show that heat is absorbed by the liquid when it changes to the vapor, and that heat is released when the vapor condenses to a liquid.

Le Châtelier's principle tells us that when we add heat to raise the temperature of the equilibrium system, the system will try to adjust in a way that absorbs some of the added heat. This can happen if some liquid evaporates, because vaporization is endothermic. When liquid evaporates, the amount of vapor increases and causes the pressure to rise. Thus, we have reached the correct conclusion in a very simple way—namely, that heating a liquid must increase its vapor pressure.

We often use the term **position of equilibrium** to refer to the relative amounts of the substances on opposite sides of the double arrows in an equilibrium expression such as Equation 12.4. Thus, we can think of how a disturbance affects the position of equilibrium. For example, increasing the temperature increases the amount of vapor and decreases the amount of liquid, and we say *the position of equilibrium has shifted*; in this case, it has shifted in the direction of the vapor, or it has *shifted to the right.* In using Le Châtelier's principle, it is often convenient to think of a disturbance as "shifting the position of equilibrium" in one direction or another in the equilibrium equation.

Practice Exercises

12.12 | Use Le Châtelier's principle to predict how a temperature increase will affect the vapor pressure of a solid. (*Hint:* Solid + heat $\rightleftharpoons$ vapor.)

12.13 | Designate whether each of the following physical processes is exothermic or endothermic: boiling, melting, condensing, subliming, and freezing. Can any of them be exothermic for some substances and endothermic for others?

12.10 | Phase Diagrams

Sometimes it is useful to know under what combinations of temperature and pressure a substance will be a liquid, a solid, or a gas, or the conditions of temperature and pressure that produce an equilibrium between any two phases. A simple way to determine this is to use a **phase diagram**—a graphical representation of the pressure–temperature relationships that apply to the equilibria between the phases of the substance.

TOOLS

Phase diagrams

Figure 12.29 is the phase diagram for water. On it, there are three lines that intersect at a common point. Equilibrium between phases exists everywhere along the lines. For example, line *BD* is the vapor pressure curve for liquid water. It gives the temperatures and pressures at which the liquid and vapor are able to coexist in equilibrium. Notice that when the temperature is 100 °C, the vapor pressure is 760 torr. Therefore, this diagram also tells us that water boils at 100 °C when the pressure is 1 atm (760 torr), because that is the temperature at which the vapor pressure equals 1 atm.

■ The melting point and boiling point can be read directly from the phase diagram.

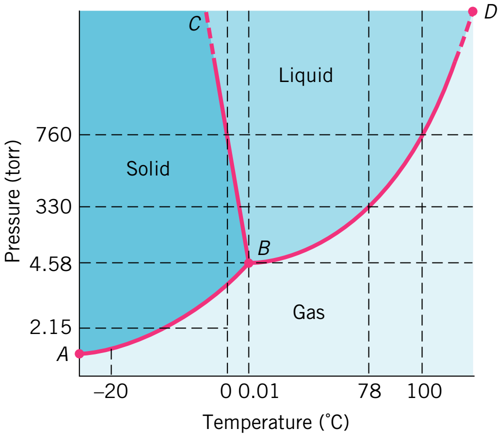

Figure 12.29 | **The phase diagram for water, distorted to emphasize certain features.** Temperatures and pressures corresponding to the dashed lines on the diagram are referred to in the text discussion.

The solid–vapor equilibrium line, *AB,* and the liquid–vapor line, *BD,* intersect at a common point, *B.* Because this point is on both lines, there is equilibrium between all three phases at the same time.

$$\begin{tikzcd}
 & \text{vapor} \arrow[dl, shift left] \arrow[dr, shift left] & \\
\text{liquid} \arrow[ur, shift left] \arrow[rr, shift left] & & \text{solid} \arrow[ul, shift left] \arrow[ll, shift left]
\end{tikzcd}$$

The temperature and pressure at which this triple equilibrium occurs define the **triple point** of the substance. For water, the triple point occurs at 0.01 °C and 4.58 torr. Every known chemical substance except helium has its own characteristic triple point, which is controlled by the balance of intermolecular forces in the solid, liquid, and vapor.

Line *BC,* which extends upward from the triple point, is the solid–liquid equilibrium line or *melting point line.* It gives temperatures and pressures at which the solid and the liquid are in equilibrium. At the triple point, the melting of ice occurs at +0.01 °C (and 4.58 torr); at 760 torr, melting occurs very slightly lower, at 0 °C. Thus, we can tell that *increasing the pressure on ice lowers its melting point.*

■ In the SI, the triple point of water is used to define the Kelvin temperature of 273.16 K.

The effect of pressure on the melting point of ice can be predicted using Le Châtelier's principle and the knowledge that a given mass of liquid water occupies *less volume* than the same mass of ice (i.e., liquid water is more dense than ice). Consider an equilibrium that is established between ice and liquid water at 0 °C and 1 atm in an apparatus like that shown in Figure 12.30.

$$H_2O(s) \rightleftharpoons H_2O(l)$$

If the piston is forced in slightly, the pressure increases. According to Le Châtelier's principle, the system should respond, if possible, in a way that reduces the pressure. This can happen if some of the ice melts, so the ice–liquid mixture won't require as much space.

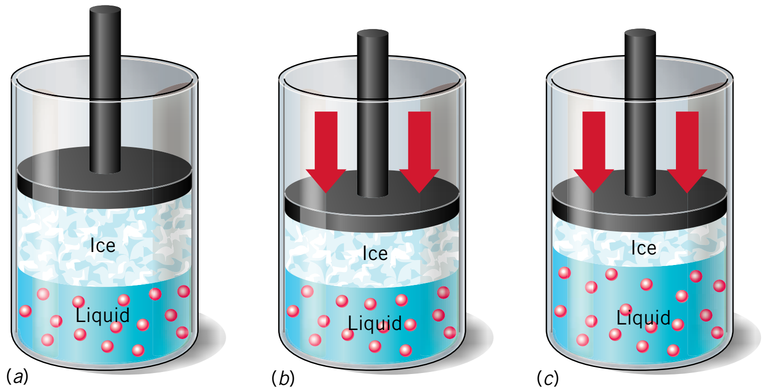

Figure 12.30 | **The effect of pressure on the equilibrium, $H_2O(solid) \rightleftharpoons H_2O(liquid)$.** (*a*) The system is at equilibrium between water as a liquid and water as a solid. (*b*) Pushing down on the piston decreases the volume of both the ice and liquid water by a small amount and increases the pressure. (*c*) Some of the ice melts, producing the more dense liquid. As the total volume of ice and liquid water decreases, the pressure drops and equilibrium is restored.

Then the molecules won't push as hard against each other and the walls, and the pressure will drop. Thus, a pressure-increasing disturbance to the system favors a volume-decreasing change, which corresponds to the melting of some ice.

Now suppose we have ice at a pressure just below the solid–liquid line, *BC.* If, *at constant temperature,* we raise the pressure to a point just above the line, the ice will melt and become a liquid. This could only happen if the melting point decreases as the pressure increases.

Water is very unusual. Almost all other substances have melting points that increase with increasing pressure, as illustrated by the phase diagram for carbon dioxide (Figure 12.31). For CO_2 the solid–liquid line slants to the right (it slanted to the left for water). Also notice that carbon dioxide has a triple point that's above 1 atm. At atmospheric pressure, the only equilibrium that can be established is between solid carbon dioxide and its vapor. At a pressure of 1 atm, this equilibrium occurs at a temperature of −78 °C. This is the temperature of dry ice, which sublimes at atmospheric pressure at −78 °C.

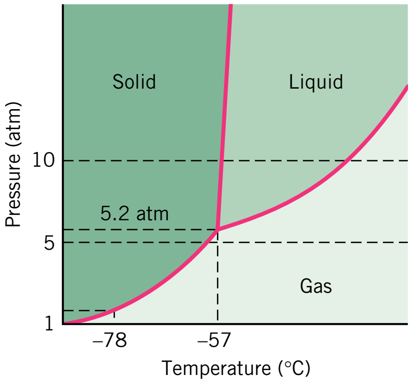

Figure 12.31 | **The phase diagram for carbon dioxide.**

Interpreting a Phase Diagram

Besides specifying phase equilibria, the three intersecting lines on a phase diagram serve to define regions of temperature and pressure at which only a single phase can exist. For example, between lines *BC* and *BD* in Figure 12.29 are temperatures and pressures at which water exists as a liquid without being in equilibrium with either vapor or ice. At 760 torr, water is a liquid anywhere between 0 °C and 100 °C. According to the diagram, we can't have ice with a temperature of 25 °C if the pressure is 760 torr (which, of course, you already knew; ice never has a temperature of 25 °C.) The diagram also says that we can't have water vapor with a pressure of 760 torr when the temperature is 25 °C (which, again, you already knew; the temperature has to be taken to 100 °C for the vapor pressure to reach 760 torr). Instead, the phase diagram indicates that the *only* phase for pure water at 25 °C and 1 atm is the liquid. Below 0 °C at 760 torr, water is a solid; above 100 °C at 760 torr, water is a vapor. On the phase diagram for water, the phases that can exist in the different temperature–pressure regions are marked.

Example 12.4
Interpreting a Phase Diagram

What phase would we expect for water at 0 °C and 4.58 torr?

■ **Analysis:** The words "What phase . . ." as well as the specified temperature and pressure, suggest that we refer to the phase diagram of water (Figure 12.29).

■ **Assembling the Tools:** The tool we will use is the phase diagram of water.

Solution: First, we find 0 °C on the temperature axis of the phase diagram of water. Then, we move upward until we intersect a line corresponding to 4.58 torr. This intersection occurs in the "solid" region of the diagram. At 0 °C and 4.58 torr, then, water exists as a solid.

Is the Answer Reasonable? We've seen that the freezing point of water increases slightly when we lower the pressure, so below 1 atm, water should still be a solid at 0 °C. That agrees with the answer we obtained from the phase diagram.

Example 12.5
Interpreting a Phase Diagram

What phase changes occur if water at 0 °C is gradually compressed from a pressure of 2.15 torr to 800 torr?

Analysis: Asking "what phase changes occur" suggests once again that we use the phase diagram of water (Figure 12.29).

Assembling the Tools: Just as in Example 12.4, the tool we will use is the phase diagram of water.

Solution: According to the phase diagram, at 0 °C and 2.15 torr, water exists as a gas (water vapor). As the vapor is compressed, we move upward along the 0 °C line until we encounter the solid–vapor line. There, an equilibrium will exist as compression gradually transforms the gas into solid ice. Once all of the vapor has frozen, further compression raises the pressure and we continue the climb along the 0 °C line until we next encounter the solid–liquid line at 760 torr. As further compression takes place, the solid will melt. After all of the ice has melted, the pressure will continue to climb while the water remains a liquid. At 800 torr and 0 °C, the water will be liquid. The phase changes are gas to solid to liquid.

Is the Answer Reasonable? There's not too much we can do to check all this except to take a fresh look at the phase diagram. We do expect that above 760 torr, the melting point of ice will be less than 0 °C, so at 0 °C and 800 torr we can anticipate that water will be a liquid.

Practice Exercises

12.14 | The equilibrium line from point *B* to *D* in Figure 12.29 is present in another figure in this chapter. Identify what that line represents. (*Hint:* A review of the other figures will reveal the nature of the line.)

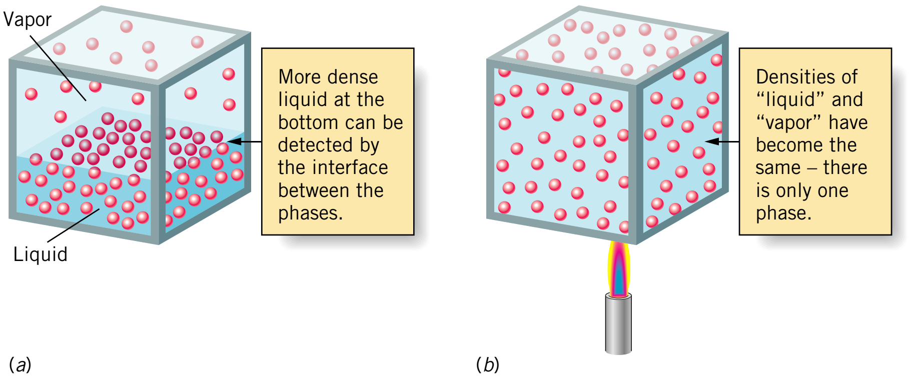
12.15 | What phase changes will occur if water at −20 °C and 2.15 torr is heated to 50 °C under constant pressure?

12.16 | What phase will water be in if it is at a pressure of 330 torr and a temperature of 50 °C?

Supercritical Fluids

For water (Figure 12.29), the vapor pressure line for the liquid, which begins at point *B*, terminates at point *D*, which is known as the **critical point**. The temperature and pressure at *D* are called the **critical temperature, T_c**, and the **critical pressure, P_c**. Above the critical temperature, a distinct liquid phase cannot exist, *regardless of the pressure.*

Figure 12.32 illustrates what happens to a substance as it approaches its critical point. In Figure 12.32*a*, we see a liquid in a container with some vapor above it. We can distinguish between the two phases because they have different densities, which causes them to bend light differently. This allows us to see the interface, or surface, between the more



Vapor
Liquid
More dense liquid at the bottom can be detected by the interface between the phases.
Densities of "liquid" and "vapor" have become the same – there is only one phase.
(a)
(b)

Figure 12.32 | **Changes that are observed when a liquid is heated in a sealed container.** (*a*) Below the critical temperature. (*b*) Above the critical temperature.

dense liquid and the less dense vapor. If this liquid is now heated, two things happen. First, more liquid evaporates. This causes an increase in the number of molecules per cubic centimeter of vapor, which, in turn, causes the density of the vapor to increase. Second, the liquid expands. This means that a given mass of liquid occupies more volume, so its density decreases. As the temperature of the liquid and vapor continue to increase, the vapor density rises and the liquid density falls; they approach each other. Eventually the densities become equal, and a separate liquid phase no longer exists; everything is the same (see Figure 12.32*b*). The highest temperature at which a liquid phase still exists is the critical temperature, and the pressure of the vapor at this temperature is the critical pressure. A substance that has a temperature above its critical temperature and a density near its liquid density is described as a **supercritical fluid**. Supercritical fluids have some unique properties that make them excellent solvents, and one that is particularly useful is supercritical carbon dioxide, which is used as a solvent to decaffeinate coffee.

CHEMISTRY OUTSIDE THE CLASSROOM | 12.1

Decaffeinated Coffee and Supercritical Carbon Dioxide

Many people prefer to avoid caffeine, yet still enjoy their cup of coffee. For them, decaffeinated coffee is just the thing. To satisfy this demand, coffee producers remove caffeine from the coffee beans before roasting them. Several methods have been used, some of which use solvents such as methylene chloride (CH_2Cl_2) or ethyl acetate ($CH_3CO_2C_2H_5$) to dissolve the caffeine. Even though only trace amounts of these solvents remain after the coffee beans are dried, there are those who would prefer not to have any such chemicals in their coffee. And that's where carbon dioxide comes into the picture.

Decaffeinated Coffee
M. ROHRS'

(Andy Washnik)

It turns out that supercritical carbon dioxide is an excellent solvent for many organic substances, including caffeine. To make supercritical carbon dioxide, gaseous CO_2 is heated to a temperature (typically ~80 °C) above its critical temperature of 31 °C. It is then compressed to about 200 atm. This gives it a density near that of a liquid, but with some properties of a gas. The fluid has a very low viscosity and readily penetrates coffee beans that have been softened with steam, drawing out the water and the caffeine. After several hours, the CO_2 has removed as much as 97% of the caffeine, and the fluid containing the water and caffeine is then drawn off. When the pressure of the supercritical CO_2 solution is reduced, the CO_2 turns to a gas and the water and caffeine separate. The caffeine is recovered and sold to beverage or pharmaceutical companies. Meanwhile, the pressure over the coffee beans is also reduced and the beans are warmed to about 120 °C, causing residual CO_2 to evaporate. Because CO_2 is not a toxic gas, any traces of CO_2 that remain are harmless.

Decaffeination of coffee is not the only use of supercritical CO_2. It is also used to extract the essential flavor ingredients in spices and herbs for use in a variety of products. As with coffee, using supercritical CO_2 as a solvent completely avoids any potential harm that might be caused by small residual amounts of other solvents.

Table 12.5 Some Critical Temperatures and Pressures

Compound	T_c (°C)	P_c (atm)
Water	374.1	217.7
Ammonia	132.5	112.5
Carbon dioxide	31	72.9
Ethane (C_2H_6)	32.2	48.2
Methane (CH_4)	−82.1	45.8
Helium	−267.8	2.3

The values of the critical temperature and critical pressure are unique for every chemical substance and are controlled by the intermolecular attractions (see Table 12.5). Notice that liquids with strong intermolecular attractions, like water, tend to have high critical temperatures. Under pressure, the strong attractions between the molecules are able to hold them together in a liquid state even when the molecules are jiggling about violently at an elevated temperature. In contrast, substances with weak intermolecular attractions, such as methane and helium, have low critical temperatures. For these substances, even the small amounts of kinetic energy possessed by the molecules at low temperatures is sufficient to overcome the intermolecular attractions and prevent the molecules from sticking together as a liquid, despite being held close together under high pressure.

Liquefaction of Gases

When a gaseous substance has a temperature below its critical temperature, it is capable of being liquefied by compressing it. For example, carbon dioxide is a gas at room temperature (approximately 25 °C). This is below its critical temperature of 31 °C. If the $CO_2(g)$ is gradually compressed, a pressure will eventually be reached that lies on the liquid–vapor curve for CO_2, and further compression will cause the CO_2 to liquefy. In fact, that's what happens when a CO_2 fire extinguisher is filled; the CO_2 that's pumped in is a liquid under high pressure. If you shake a filled CO_2 fire extinguisher, you can feel the liquid sloshing around inside, provided the temperature of the fire extinguisher is below 31 °C (88 °F). When the fire extinguisher is used, a valve releases the pressurized CO_2, which rushes out to extinguish the fire.

Gases such as O_2 and N_2, which have critical temperatures far below 0 °C, can never be liquids at room temperature. When they are compressed, they simply become high-pressure gases. To make liquid N_2 or O_2, the gases must be made very cold as well as be compressed to high pressures.

■ On a very hot day, when the temperature is in the 90s, a filled CO_2 fire extinguisher won't give the sensation that it's filled with a liquid. At such temperatures, the CO_2 is in a supercritical state and no separate liquid phase exists.

■ A high degree of regularity is the principal feature that makes solids different from liquids. A liquid lacks this long-range repetition of structure because the particles in a liquid are jumbled and disorganized as they move about.

12.11 | Structures of Crystalline Solids

When many substances freeze, or when they separate as a solid from a solution, they tend to form crystals that have highly regular features. For example, Figure 12.33 is a photograph of crystals of sodium chloride—ordinary table salt. Notice that each particle is very nearly a perfect little cube. Whenever a solution of NaCl is evaporated, the crystals that form have edges that intersect at 90° angles. Thus, cubes are the norm for NaCl.

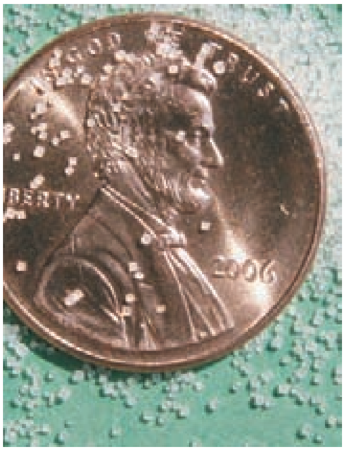


Figure 12.33 | **Crystals of table salt.** The size of the tiny cubic sodium chloride crystals can be seen in comparison with a penny. *(The Photo Works)*

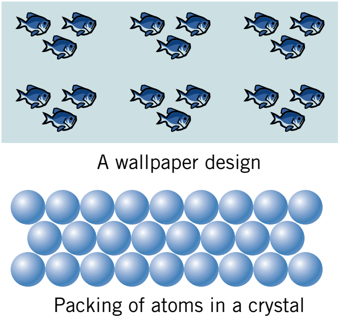
Crystals in general tend to have flat surfaces that meet at angles that are characteristic of the substance. The regularity of these surface features reflects the high degree of order among the particles that lie within the crystal. This is true whether the particles are atoms, molecules, or ions.

Lattices and Unit Cells

Any repetitive pattern has a symmetrical aspect about it, whether it is a wallpaper design or the orderly packing of particles in a crystal (Figure 12.34). For example, we can recognize certain repeating distances between the elements of the pattern, and we can see that the lines along which the elements of the pattern repeat are at certain angles to each other.

To concentrate on the symmetrical features of a repeating structure, it is convenient to describe it in terms of a set of points that have the same repeat distances as the structure, arranged along lines oriented at the same angles. Such a pattern of points is called a **lattice**,



A wallpaper design
Packing of atoms in a crystal

Figure 12.34 | **Symmetry among repetitive patterns.** A wallpaper design and particles arranged in a crystal each show a repeating pattern of structural units. The pattern can be described by the distances between the repeating units and the angles along which the repetition of structure occurs.

and when we apply it to describe the packing of particles in a solid, we often call it a **crystal lattice.**

In a crystal, the number of particles is enormous. If you could imagine being at the center of even the tiniest crystal, you would find that the particles go on as far as you can see in every direction. Describing the positions of all these particles or their lattice points is impossible and, fortunately, unnecessary. All we need to do is describe the repeating unit of the lattice, which we call the *unit cell*. To see this, and to gain an insight into the usefulness of the lattice concept, let's begin in two dimensions.

In Figure 12.35, we see a two-dimensional *square lattice*, which means the lattice points lie at the corners of squares. The repeating unit of the lattice, its **unit cell**, is indicated in the drawing. If we began with this unit cell, we could produce the entire lattice by moving it repeatedly left and right and up and down by distances equal to its edge length. In this sense, all of the properties of a lattice are contained in the properties of its unit cell.

An important fact about lattices is that the same lattice can be used to describe many different designs or structures. For example, in Figure 12.35*b*, we see a design formed by associating a pink heart with each lattice point. Using a square lattice, we could form any number of designs just by using different design elements (for example, a rose or a diamond) or by changing the lengths of the edges of the unit cell. *The only requirement is that the same design element must be associated with each lattice point.* In other words, if there is a rose at one lattice point, then there must be a rose at all the other lattice points.

Extending the lattice concept to three dimensions is relatively straightforward. Illustrated in Figure 12.36 is a **simple cubic** (also called a **primitive cubic**) lattice, the simplest and most symmetrical three-dimensional lattice. Its unit cell, the **simple cubic unit cell**, is a cube with lattice points only at its eight corners. Figure 12.36*c* shows the packing of atoms in a substance that might crystallize in a simple cubic lattice, as well as the unit cell for that substance.[3]

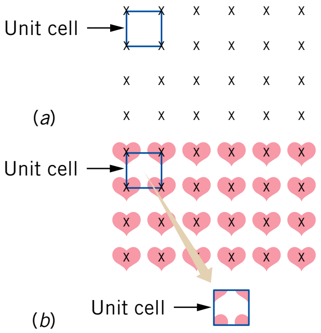


Figure 12.35 | **A two-dimensional lattice.** (*a*) A simple square lattice, for which the unit cell is a square with lattice points at the corners. (*b*) A wallpaper pattern formed by associating a design element (pink heart) with each lattice point. The x centered on each heart corresponds to a lattice point. The unit cell contains portions of a heart at each corner.

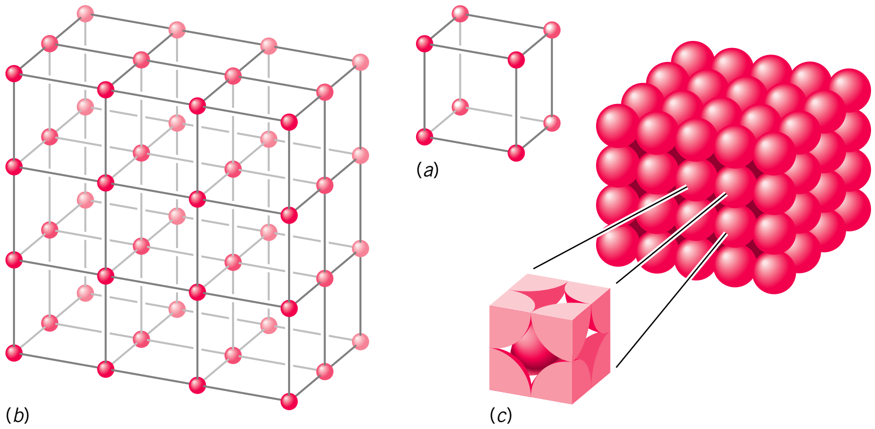

Figure 12.36 | **A three-dimensional simple cubic lattice.** (*a*) A simple cubic unit cell showing the locations of the lattice points. (*b*) A portion of a simple cubic lattice built by stacking simple cubic unit cells. (*c*) A hypothetical substance that forms crystals having a simple cubic lattice with identical atoms at the lattice points. Only a portion of each atom lies within this particular unit cell.

---

[3] Polonium is the only metal that has an allotrope that crystallizes in a simple cubic lattice. Some compounds, however, do form simple cubic lattices.

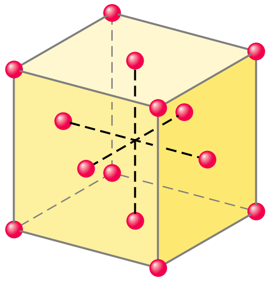

Figure 12.37 | **A face-centered cubic unit cell.** Lattice points are found at each of the eight corners and in the center of each face.

As with the two-dimensional lattice, we could use the same simple cubic lattice to describe the structures of many different substances. The *sizes* of the unit cells would vary because the sizes of atoms vary, but the essential symmetry of the stacking would be the same in them all. This fact about lattices makes it possible to describe limitless numbers of different compounds with just a limited set of three-dimensional lattices. In fact, it has been shown mathematically that there are only 14 different three-dimensional lattices possible, which means that all of the chemical substances that can exist must form crystals with one or another of these 14 lattice types.

The 14 lattice types are shown in Table 12.6. There are seven basic lattice shapes, which depend on the lengths of the sides, a_1, a_2, and a_3, and the angles between the edges of the shapes, α_{12}, α_{23}, and α_{13}. The variations on the basic shapes give the lattice types. The simple shape only has lattice points in the corners of the lattice. The body-centered structures have lattice points in the middle of the cells. The base-centered structures have a lattice point on two opposing faces, and the face-centered structures have lattice points on all of the faces.

Cubic Lattices

TOOLS

Cubic unit cells

Cubic lattices are the simplest lattices because all of the sides have the same length and all of the angles are 90°. In addition to simple cubic, two other cubic lattices are possible: face-centered cubic and body-centered cubic. The **face-centered cubic** (abbreviated **fcc**) **unit cell** has lattice points (and, therefore, identical particles) at each of its eight corners plus another in the center of each face, as shown in Figure 12.37. Many common metals—copper, silver, gold, aluminum, and lead, for example—form crystals that have face-centered cubic lattices. Each of these metals has the same *kind* of lattice, but the *sizes* of their unit cells differ because the sizes of the atoms differ (see Figure 12.38).

The **body-centered cubic (bcc) unit cell** has lattice points at each corner plus one in the center of the cell, as illustrated in Figure 12.39. The body-centered cubic lattice is also common among a number of metals; examples include chromium, iron, and platinum. Again, these are substances with the same *kind* of lattice, but the dimensions of the lattices vary because of the *different sizes* of the particular atoms.

Not all unit cells are cubic. Some have edges of different lengths or edges that intersect at angles other than 90°, as shown in Table 12.6. Although you should be aware of the existence of other unit cells and lattices, we will limit the remainder of our discussion to cubic lattices and their unit cells.

TOOLS

Counting atoms in unit cells

If we look at the unit cell of the face-centered cubic structure of copper in Figure 12.38, we can see that the atoms are cut up into parts. We can show that the parts add up to whole atoms. Notice that when the unit cell is "carved out" of the crystal, we find only part

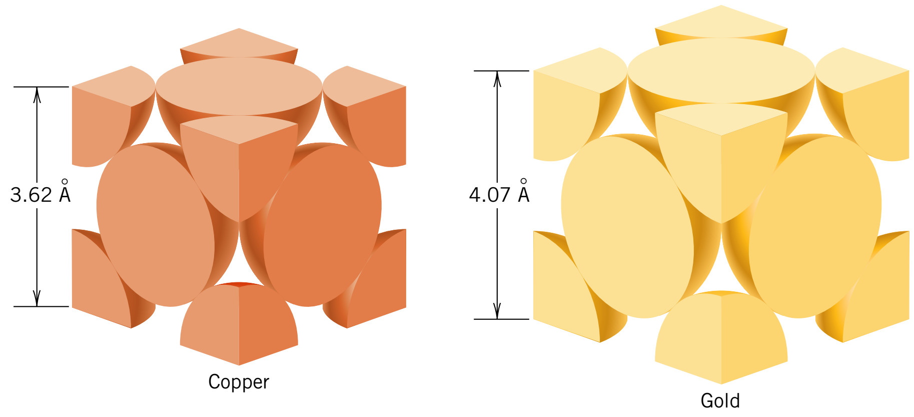

Figure 12.38 | **Unit cells for copper and gold.** These metals both crystallize in a face-centered cubic structure with similar face-centered cubic unit cells. The atoms are arranged in the same way, but their unit cells have edges of different lengths because the atoms are of different sizes. (1 Å = 1×10^{-10} m)

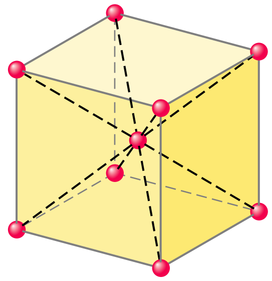

Figure 12.39 | **A body-centered cubic unit cell.** Lattice points are located at each of the eight corners and in the center of the unit cell.

Table 12.6 Crystal Lattice Types

The 7 Lattices		The 14 Lattice Types			
		Simple	Body-Centered	Base-Cenrered	Face-Centered
Triclinic	$a_1 \neq a_2 \neq a_3$ $\alpha_{12} \neq \alpha_{23} \neq \alpha_{31} \neq 90°$				
Monoclinic	$a_1 \neq a_2 \neq a_3$ $\alpha_{23} = \alpha_{31} = 90°$ $\alpha_{12} \neq 90°$				
Orthorhombic	$a_1 \neq a_2 \neq a_3$ $\alpha_{12} = \alpha_{23} = \alpha_{31} = 90°$				Tetragonal	$a_1 = a_2 \neq a_3$ $\alpha_{12} = \alpha_{23} = \alpha_{31} = 90°$				
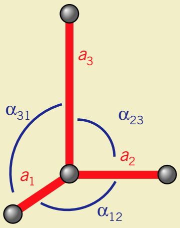
Trigonal	$a_1 = a_2 = a_3$ $\alpha_{12} = \alpha_{23} = \alpha_{31} < 120° \neq 90°$				
Hexagonal	$a_1 = a_2 \neq a_3$ $\alpha_{12} = 120°$ $\alpha_{23} = \alpha_{31} = 90°$				
Cubic	$a_1 = a_2 = a_3$ $\alpha_{12} = \alpha_{23} = \alpha_{31} = 90°$				



of an atom ($\frac{1}{8}$th of an atom, actually) at each corner. The rest of each atom resides in adjacent unit cells. Because the unit cell has eight corners, if we put all the corner pieces together we would obtain one complete atom.

$$8 \text{ corners} \times \frac{\frac{1}{8} \text{ atom}}{\text{corner}} = 1 \text{ atom}$$

Now, if we look at the atoms in the face, only half of each atom lies inside of the unit cell, but there are six faces and therefore six half atoms, for a total of three atoms.

$$6 \text{ corners} \times \frac{\frac{1}{2} \text{ atom}}{\text{corner}} = 3 \text{ atoms}$$

The total number of atoms in the unit cell is four atoms: three from the faces and one from the corners. In addition, if an atom is on the edge of a cube, then it contributes $\frac{1}{4}$ of an atom to the unit cell.

Compounds that Crystallize with Cubic Lattices

We have seen that a number of metals have cubic lattices. The same is true for many compounds. Figure 12.40, for example, is a view of a portion of a sodium chloride crystal. The Cl^- ions (green) are shown at the lattice points that correspond to a face-centered cubic unit cell. The smaller gray spheres represent Na^+ ions. Notice that they fill the spaces between the Cl^- ions. If we look at the locations of identical particles (e.g., Cl^-), we find them at lattice points that describe a face-centered cubic structure. Thus, sodium chloride is said to have a face-centered cubic lattice, and the cubic shape of this lattice is what accounts for the cubic shape of a sodium chloride crystal.

Many of the alkali halides (Group 1A–7A compounds), such as NaBr and KCl, crystallize with fcc lattices that have the same arrangement of ions as is found in NaCl. In fact, this arrangement of ions is so common that it's called the **rock salt structure** (rock salt is the mineral name of NaCl). Because sodium bromide and potassium chloride both have the same kind of lattice as sodium chloride, Figure 12.40 also could be used to describe their unit cells. The *sizes* of their unit cells are different, however, because K^+ is larger than Na^+ and Br^- is larger than Cl^-.

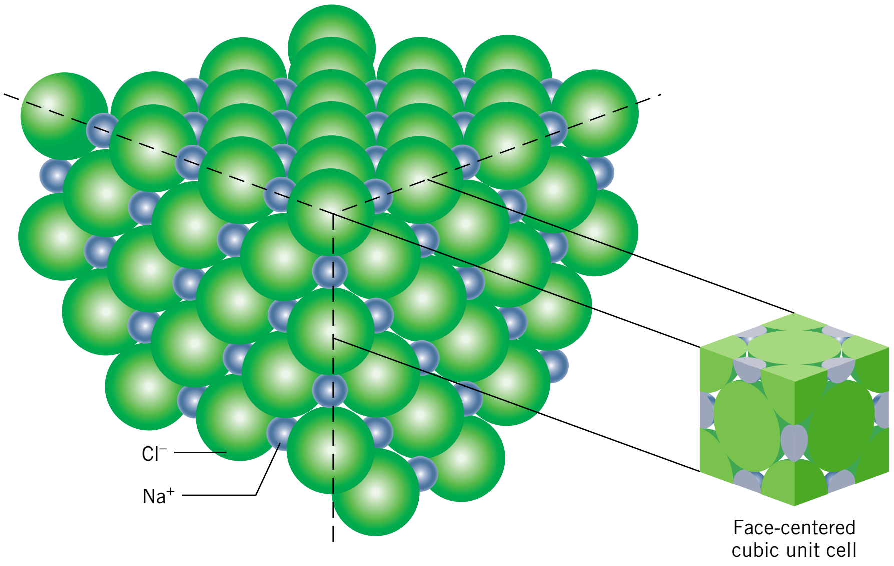


Figure 12.40 | **The packing of ions in a sodium chloride crystal.** Chloride ions are shown here to be associated with the lattice points of a face-centered cubic unit cell, with the sodium ions placed between the chloride ions.

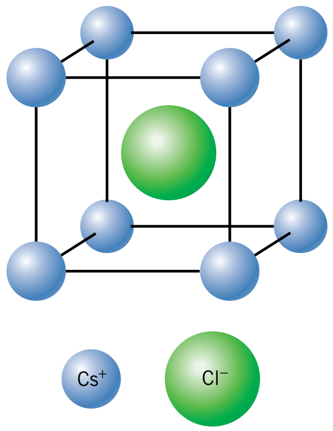

Figure 12.41 | **The unit cell for cesium chloride, CsCl.** The chloride ion is located in the center of the unit cell. The ions are not shown full-size to make it easier to see their locations in the unit cell.

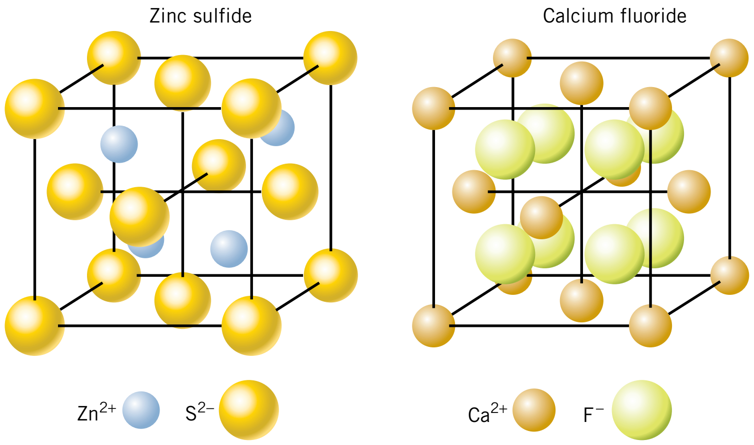

Figure 12.42 | **Crystal structures based on the face-centered cubic lattice.** Both zinc sulfide, ZnS, and calcium fluoride, CaF_2, have crystal structures that fit a face-centered cubic lattice. In ZnS, the sulfide ions are shown at the fcc lattice sites with the four zinc ions entirely within the unit cell. In CaF_2, the calcium ions are at the lattice points with the eight fluorides entirely within the unit cell. *Note:* The ions are not shown full-size to make it easier to see their locations in the unit cells.

Other examples of cubic unit cells are shown in Figures 12.41 and 12.42. The structure of cesium chloride in Figure 12.41 is simple cubic, although at first glance it may appear to be body-centered. This is because in a crystal lattice, identical chemical units must be at each lattice point. In CsCl, Cs^+ ions are found at the corners, but not in the center, so the Cs^+ ions describe a simple cubic unit cell.

Both zinc sulfide and calcium fluoride in Figure 12.42 have face-centered cubic unit cells that differ from that for sodium chloride, which illustrates once again how the same basic kind of lattice can be used to describe a variety of chemical structures.

Effects of Stoichiometry on Crystal Structure

At this point, you may wonder why a compound crystallizes with a particular structure. Although this is a complex issue, at least one factor is the stoichiometry of the substance. Because the crystal is made up of a huge number of identical unit cells, the stoichiometry within the unit cell must match the overall stoichiometry of the compound. Let's see how this applies to sodium chloride.

Example 12.6

Counting Atoms or Ions in a Unit Cell

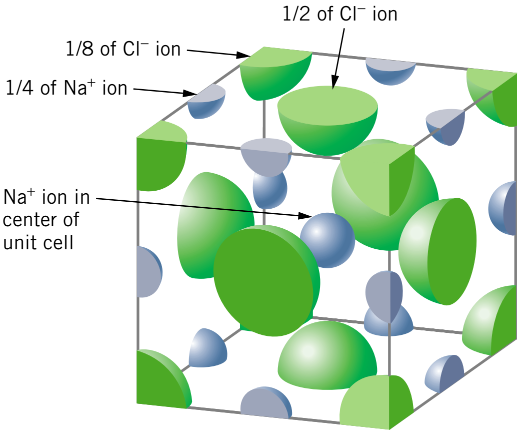
How many sodium and chloride ions are there in the unit cell of sodium chloride?

■ **Analysis:** To answer this question, we have to look closely at the unit cell of sodium chloride. The critical link is realizing that when the unit cell is carved out of the crystal, it encloses *parts of ions*, so we have to determine how many *whole* sodium and chloride ions can be constructed from the pieces within a given unit cell.

■ **Assembling the Tools:** We will use the tools of counting atoms in the unit cell of sodium chloride to see how many parts of atoms there are in the unit cell.

■ **Solution:** Let's look at the "exploded" view of the NaCl unit cell shown in Figure 12.43. We have parts of chloride ions at the corners and in the center of each face. Let's add the parts.

Figure 12.43 | **An exploded view of the unit cell of sodium chloride.**



For chloride:

$$8 \text{ corners} \times \frac{1}{8}\text{Cl}^- \text{ per corner} = 1\ \text{Cl}^-$$
$$6 \text{ faces} \times \frac{1}{2}\text{Cl}^- \text{ per face} = 3\ \text{Cl}^-$$
$$\text{Total} = 4\ \text{Cl}^-$$

For the sodium ions, we have parts along each of the 12 edges plus one whole Na^+ ion in the center of the unit cell. Let's add them.

For sodium:

$$12 \text{ edges} \times \frac{1}{4}\text{Na}^+ \text{ per edge} = 3\ \text{Na}^+$$
$$1\ \text{Na}^+ \text{ in the center} = 1\ \text{Na}^+$$
$$\text{Total} = 4\ \text{Na}^+$$

Thus, in one unit cell, there are four chloride ions and four sodium ions.

■ **Is the Answer Reasonable?** The ratio of the ions is 4 to 4, which is the same as 1 to 1. That's the ratio of the ions in NaCl, so the answer is reasonable.

Practice Exercises

12.17 | Chromium crystallizes in a body centered cubic structure. How many chromium atoms are in its unit cell? (*Hint:* Use Figure 12.39 as a guide.)

12.18 | What is the ratio of the ions in the unit cell of cesium chloride, which is shown in Figure 12.41? Does this match the formula of cesium chloride? Why is this important?

The calculation in Example 12.6 shows why NaCl can have the crystal structure it does; the unit cell has the proper ratio of cations to anions. It also shows why a compound such as $CaCl_2$ could *not* crystallize with the same kind of unit cell as NaCl. The sodium chloride structure demands a 1 to 1 ratio of cation to anion, so it could not be used by $CaCl_2$ (which has a 1 to 2 cation-to-anion ratio).

Closest-Packed Solids

For many solids, particularly metals, the type of crystal structure formed is controlled by maximizing the number of neighbors that surround a given atom. The more neighbors an atom has, the greater are the number of interatomic attractions and the greater is the

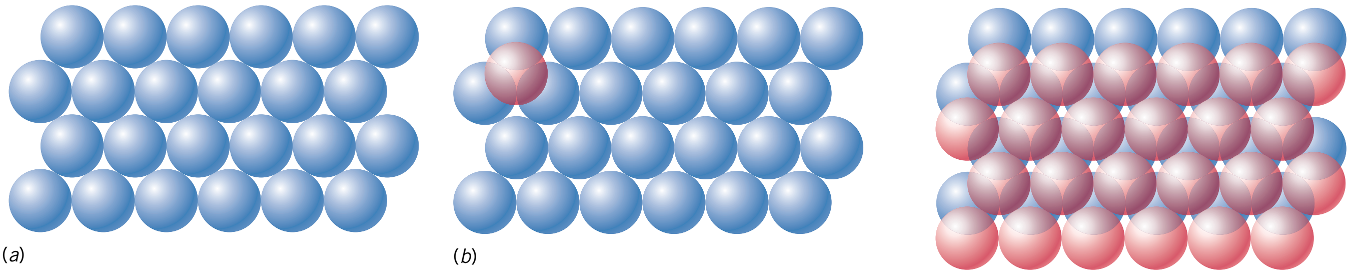


Figure 12.44 | **Packing of spheres.** (*a*) One layer of closely packed spheres. (*b*) A second layer is started by placing a sphere (colored red) in a depression formed between three spheres in the first layer. (*c*) A second layer of sphere shown slightly transparent so we can see how the atoms are stacked over the first layer.

energy lowering when the solid forms. Structures that achieve the maximum density of packing are known as **closest-packed structures**, and there are two of them that are only slightly different. To visualize how these are produced, let's look at ways to pack spheres of identical size.

Figure 12.44*a* illustrates a layer of blue spheres packed as tightly as possible. Notice that each sphere is surrounded by six others that it touches in this layer. When we add a second layer, each sphere (red) rests in a depression formed by three spheres in the first layer, as illustrated in Figures 12.44*b* and 12.44*c*.

The difference between the two closest-packed structures lies in the relative orientations of the spheres in the first layer and those that form the third layer. In Figure 12.45*a*, the green spheres in the third layer each lie in a depression between red spheres that is directly above a depression between blue spheres in the first layer—that is, none of these three layers is directly above each other. This kind of packing is called **cubic closest packing**, abbreviated **ccp**, because when viewed from a different perspective, the atoms are located at positions corresponding to a face-centered cubic lattice (Figure 12.46*a*). Figure 12.45*b* describes the other closest-packed structure in which a green sphere in the third layer rests in a depression between red spheres and directly above a blue sphere in the first

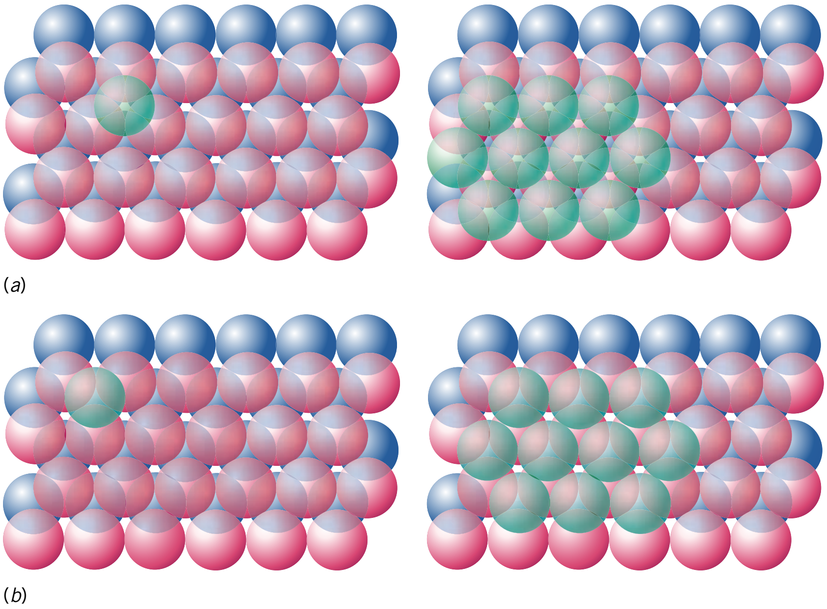

Figure 12.45 | **Closest-packed structures.** (*a*) Cubic closest packing of spheres. (*b*) Hexagonal closest packing of spheres. In both (*a*) and (*b*) the left diagram illustrates the position of one atom on the third layer and the right diagram shows the third layer partially complete. Notice that there are subtle differences between the two modes of packing.

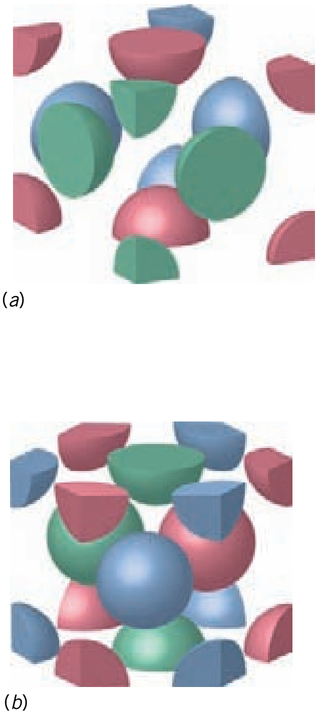

Figure 12.46 | **Unit cells of closest-packed structures.** (*a*) Cubic closest packing of spheres. (*b*) Hexagonal closest packing of spheres.

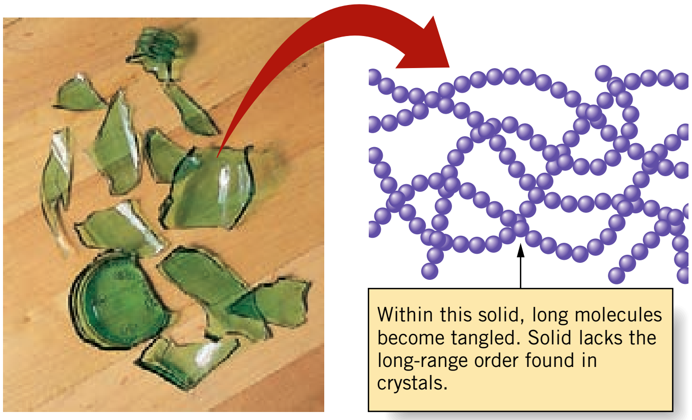
layer. This arrangement of spheres is called **hexagonal closest packing,** abbreviated **hcp** (Figure 12.46*b*). This corresponds to the hexagonal structure shown in Table 12.6.

In the hcp structure, the layers alternate in an A-B-A-B . . . pattern, where A stands for the orientations of the first, third, fifth, etc., layers, and B stands for the orientations of the second, fourth, sixth, etc., layers. Thus, the spheres in the third, fifth, seventh, etc., layers are directly above those in the first, while spheres in the fourth, sixth, eighth, etc., layers are directly above those in the second. In the ccp structure, there is an A-B-C-A-B-C. . . pattern. The first layer is oriented like the fourth, the second like the fifth, and the third like the sixth.

Both the ccp and hcp structures yield very efficient packing of identically sized atoms. In both structures, each atom is in contact with 12 neighboring atoms—six atoms in its own layer, three atoms in the layer below, and three atoms in the layer above. Metals that crystallize with the ccp structure include copper, silver, gold, aluminum, and lead. Metals with the hcp structure include titanium, zinc, cadmium, and magnesium.



Within this solid, long molecules become tangled. Solid lacks the long-range order found in crystals.

Figure 12.47 | **Glass is a noncrystalline solid.** When glass breaks, the pieces have sharp edges, but their surfaces are not flat planes. This is because in an amorphous solid like glass, long molecules (much simplified here for clarity) are tangled and disorganized, so there is no long-range order characteristic of a crystal. *(Robert Capece)*

Noncrystalline Solids

If a cubic salt crystal is broken, the pieces still have flat faces that intersect at 90° angles. If you shatter a piece of glass, on the other hand, the pieces often have surfaces that are not flat. Instead, they tend to be smooth and curved (see Figure 12.47). This behavior illustrates a major difference between crystalline solids, such as NaCl, and noncrystalline solids, also called **amorphous solids**, such as glass.

The word *amorphous* is derived from the Greek word *amorphos,* which means "without form." Amorphous solids do not have the kinds of long-range repetitive internal structures that are found in crystals. In some ways their structures, being jumbled, are more like liquids than solids. Examples of amorphous solids are ordinary glass and many plastics. In fact, the word **glass** is often used as a general term to refer to any amorphous solid.

As suggested in Figure 12.47, substances that form amorphous solids often consist of long, chain-like molecules that are intertwined in the liquid state somewhat like long strands of cooked spaghetti. To form a crystal from the melted material, these long molecules would have to become untangled and line up in specific patterns. However, as the liquid cools, the molecules slow down. Unless the liquid is cooled extremely slowly, the molecular motion decreases too rapidly for the untangling to take place, and the substance solidifies with the molecules still intertwined. As a result, amorphous solids are sometimes described as **supercooled liquids**, a term suggesting the kind of structural disorder found in liquids.

■ Some scientists prefer to reserve the term *solid* for crystalline substances, so they refer to amorphous solids as *supercooled liquids*.

12.12 | X-Ray Diffraction of Solids

When atoms in a crystal are bathed in X rays, they absorb some of the radiation and then emit it again in all directions. In effect, each atom becomes a tiny X-ray source. If we look at radiation from two such atoms (Figure 12.48), we find that the X rays emitted are in phase in some directions but out of phase in others. In Chapter 8 you learned that constructive (in-phase) and destructive (out-of-phase) interferences create a phenomenon called *diffraction*. X-ray diffraction by crystals has enabled many scientists to win Nobel prizes by determining the structures of extremely complex compounds in a particularly elegant way.

■ The 2009 Nobel Prize in chemistry was awarded for the X-ray structure of the ribosome, the part of a cell where proteins are formed.

In a crystal, there are enormous numbers of atoms, evenly spaced throughout the lattice. When a beam of X rays strikes a crystal, the radiation is diffracted because of constructive interference, and appears only in specific directions. In other directions, no

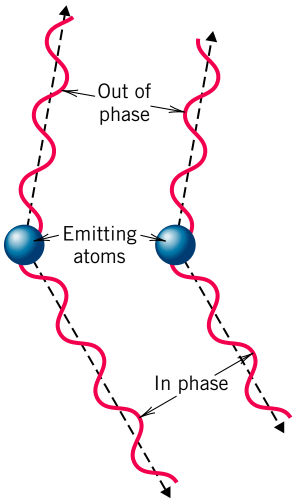


Figure 12.48 | **The diffraction of X rays from atoms in a crystal.** X rays emitted from atoms are in phase in some directions and out of phase in other directions.

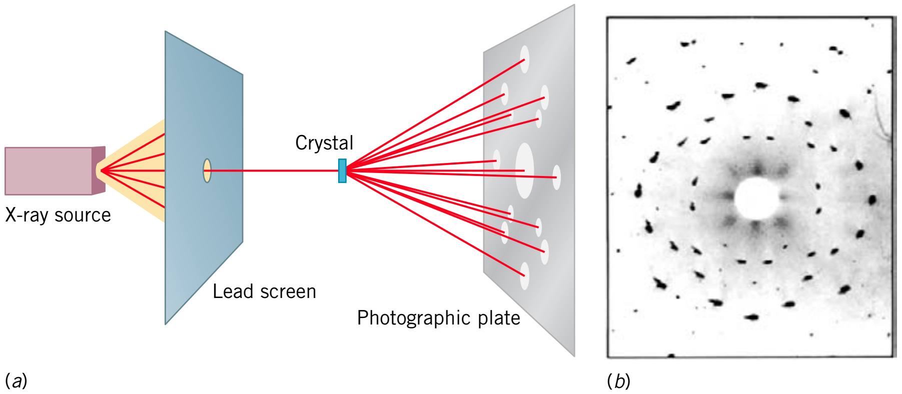

Figure 12.49 | **X-ray diffraction.** (*a*) The production of an X-ray diffraction pattern. (*b*) An X-ray diffraction pattern produced by sodium chloride recorded on photographic film. *(Visuals Unlimited)*

X rays appear because of destructive interference. When the X rays coming from the crystal fall on photographic film, the diffracted beams form a **diffraction pattern** (see Figure 12.49). The film is darkened only where the X rays strike.[4]

In 1913, the British physicist William Henry Bragg and his son William Lawrence Bragg discovered that just a few variables control the appearance of an X-ray diffraction pattern. These are shown in Figure 12.50, which illustrates the conditions necessary to obtain constructive interference of the X rays from successive layers of atoms (planes of atoms) in a crystal. A beam of X rays having a wavelength λ strikes the layers at an angle θ. Constructive interference causes an intense diffracted beam to emerge at the same angle θ. The Braggs derived an equation, now called the **Bragg equation**, relating λ, θ, and the distance between the planes of atoms, d,

$$n\lambda = 2d \sin\theta \tag{12.5}$$

TOOLS Bragg equation

where n is a whole number. The Bragg equation is the basic tool used by scientists in the study of solid structures.

Figure 12.50 | **The diffraction of X rays from successive layers of atoms in a crystal.** The layers of atoms are separated by a distance d. The X rays of wavelength λ enter and emerge at an angle θ relative to the layers of the atoms. For the emerging beam of X rays to have any intensity, the condition $n\lambda = 2d \sin\theta$ must be fulfilled, where n is a whole number.

---

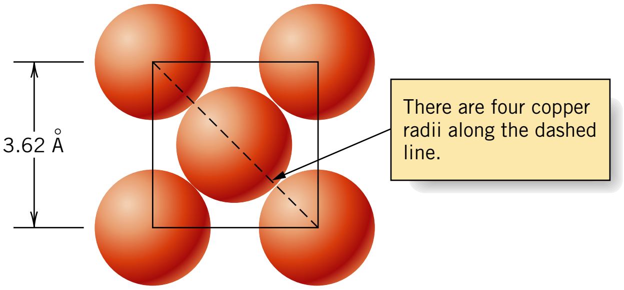
[4] Modern X-ray diffraction instruments use electronic devices to detect and measure the angles and intensities of the diffracted X rays.

To determine the structure of a crystal, the angles θ at which diffracted X-ray beams emerge from a crystal are measured. These angles are used to calculate the distances between the various planes of atoms in the crystal. The calculated interplanar distances are then used to work backward to deduce where the atoms in the crystal must be located so that layers of atoms are indeed separated by these distances. For complicated molecules and proteins, this is not a simple task, and some sophisticated mathematics as well as computers are needed to accomplish it. The efforts, however, are well rewarded because the calculations give the locations of atoms within the unit cell and the distances between them. This information, plus a lot of chemical "common sense," is used by chemists to arrive at the shapes and sizes of the molecules in the crystal. Example 12.7 illustrates how such data are used.

Example 12.7
Using Crystal Structure Data to Calculate Atomic Sizes

X-ray diffraction measurements reveal that copper crystallizes with a face-centered cubic lattice in which the unit cell length is 3.62 Å (see Figure 12.38). What is the radius of a copper atom expressed in angstroms and in picometers?

Analysis: We are given the length of the unit cell, 3.62 Å, and the shape of the unit cell, face-centered cubic. In Figure 12.38, we see that copper atoms are in contact along a diagonal (the dashed line) that runs from one corner of a face to another corner.



By geometry, we can calculate the length of this diagonal, which equals four times the radius of a copper atom. Once we calculate the radius in angstrom units we can convert to picometers.

Assembling the Tools: The two tools we will use are the arrangement of the atoms in the shape of the unit cell and the equation for determining the lengths of the sides of a right triangle, *a* and *b*, and the hypotenuse, *d* (the dotted line in the figure above):

$$a^2 + b^2 = d^2$$

Also, we will use the conversion factors for converting angstroms to picometers:

$$1\ \text{Å} = 1 \times 10^{-10}\ \text{m}$$
$$1\ \text{pm} = 1 \times 10^{-12}\ \text{m}$$

Solution: The unit cell is a cube, so the two sides of the triangle are the same length, l. Using the equation $a^2 + b^2 = d^2$, we can substitute l for a and b and rearrange the equation

$$l^2 + l^2 = d^2$$
$$2l^2 = d^2$$
$$\sqrt{2l^2} = d$$
$$\sqrt{2} \times l = d$$

We can now substitute in the actual length of the side of the unit cell and solve it.

$$\text{d} = \sqrt{2} \times (3.62\ \text{Å}) = 5.12\ \text{Å}$$

If we call the radius of the copper atom r_{Cu}, then the diagonal equals $4 \times r_{\text{Cu}}$. Therefore,

$$\begin{aligned} 4 \times r_{\text{Cu}} &= 5.12\ \text{Å} \\ r_{\text{Cu}} &= 1.28\ \text{Å} \end{aligned}$$

The calculated radius of the copper atom is 1.28 Å.

Next, we convert this to picometers:

$$1.28\ \cancel{\text{Å}} \times \frac{1 \times 10^{-10}\ \cancel{\text{m}}}{1\ \cancel{\text{Å}}} \times \frac{1\ \text{pm}}{1 \times 10^{-12}\ \cancel{\text{m}}} = 128\ \text{pm}$$

■ **Is the Answer Reasonable?** It's difficult to get an intuitive feel for the sizes of atoms, so we should be careful to check the calculation. The length of the diagonal seems about right; it is longer than the edge of the unit cell. If we look again at the diagram above, we can see that along the diagonal there are four copper radii. The rest of the arithmetic is okay, so our answer is correct.

12.13 | Crystal Types and Physical Properties

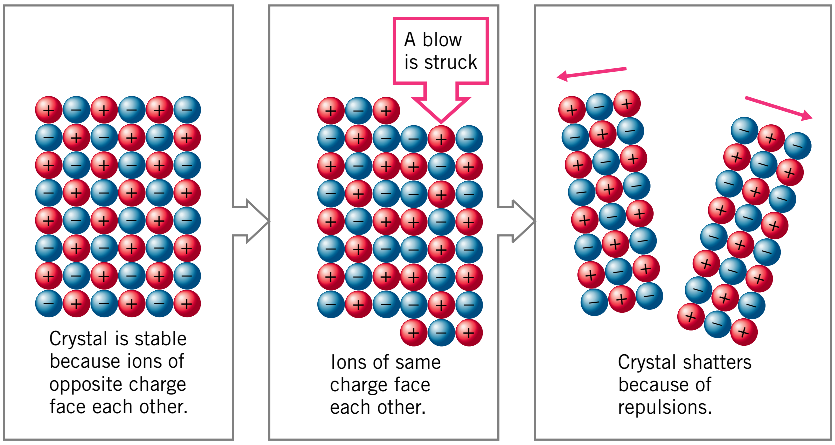
Solids exhibit a wide range of properties. Some, such as diamond, are very hard, whereas others, such as ice and naphthalene (moth flakes), are relatively soft. Some, such as salt crystals, have high melting points whereas others, such as candle wax, melt at low temperatures. Also, some conduct electricity, but others are nonconducting. Physical properties such as these depend on the kinds of particles in the solid as well as on the strengths of the attractive forces holding the solid together. Even though we can't make exact predictions about such properties, some generalizations do exist. In discussing them, it is convenient to divide crystals into four types: ionic, molecular, covalent, and metallic.

Ionic Crystals

Ionic crystals have ions at the lattice sites and the binding between them is mainly electrostatic, which is essentially non-directional. As a result, the kind of lattice formed is determined mostly by the relative sizes of the ions and their charges. When the crystal forms, the ions arrange themselves to maximize attractions and minimize repulsions.

Because electrostatic forces are strong, ionic crystals tend to be hard. They also tend to have high melting points because the ions have to be given a lot of kinetic energy to enable them to break free of the lattice and enter the liquid state. The forces between ions can also be used to explain the brittle nature of many ionic compounds. For example, when struck by a hammer, a salt crystal shatters into many small pieces. A view at the atomic level reveals how this could occur (Figure 12.51). The slight movement of a layer of ions within an ionic crystal suddenly places ions of the *same* charge next to each other, and for that instant there are large repulsive forces that split the solid.

In the solid state, ionic compounds do not conduct electricity because the charges present are not able to move. However, when melted, ionic compounds are good conductors of electricity. Melting frees the electrically charged ions to move.



A blow is struck
Crystal is stable because ions of opposite charge face each other.
Ions of same charge face each other.
Crystal shatters because of repulsions.

Figure 12.51 | **An ionic crystal shatters when struck.** In this microview we see that striking an ionic crystal causes some of the layers to shift. This can bring ions of like charge face to face. The repulsions between the ions can then force parts of the crystal apart, causing the crystal to shatter.

Molecular Crystals

■ Molecular crystals are soft because little energy is needed to separate the particles or cause them to move past each other.

Molecular crystals are solids in which the lattice sites are occupied either by atoms (as in solid argon or krypton) or by molecules (as in solid sulfur, PF_5, SO_2, or H_2O). If the molecules of such solids are relatively small, the crystals tend to be soft and have low melting points because the particles in the solid experience relatively weak intermolecular attractions. In crystals of argon, for example, the attractive forces are exclusively London forces. In SO_2, which is composed of polar molecules, there are dipole–dipole attractions as well as London forces. And, in water crystals (ice), the molecules are held in place primarily by strong hydrogen bonds. Molecular compounds do not conduct electricity either in the solid or liquid state because they are unable to transport electrical charges.

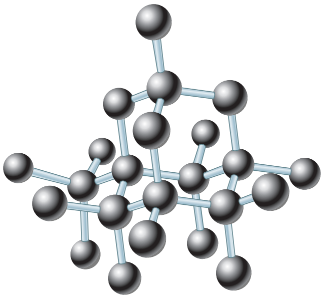


Figure 12.52 | **The structure of diamond.** Each carbon atom is covalently bonded to four others at the corners of a tetrahedron. This is just a tiny portion of a diamond; the structure extends throughout the entire diamond crystal.

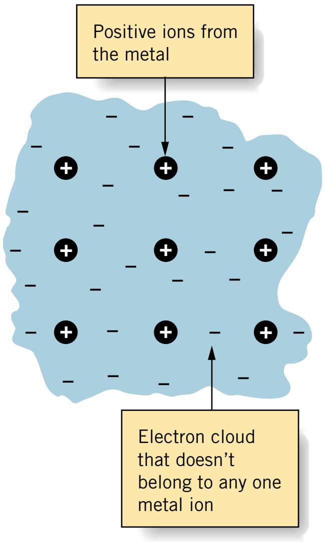
Covalent Crystals

Covalent crystals are solids in which lattice positions are occupied by atoms that are covalently bonded to other atoms at neighboring lattice sites. The result is a crystal that is essentially one gigantic molecule. These solids are sometimes called **network solids** because of the interlocking network of covalent bonds extending throughout the crystal in all directions. A typical example is diamond (see Figure 12.52). Covalent crystals tend to be very hard and to have very high melting points because of the strong attractions between covalently bonded atoms. Other examples of covalent crystals are quartz (SiO_2, found in some types of sand) and silicon carbide (SiC, a common abrasive used in sandpaper). Covalent crystals are poor conductors of electricity, although some, such as silicon, are semiconductors.

Metallic Crystals

■ The band theory of solids discussed in Chapter 10 takes a close look at electronic structures of different kinds of solids.

Metallic crystals have properties that are quite different from those of the other three types. Metallic crystals conduct heat and electricity well, and they have the luster characteristically associated with metals. A number of different models have been developed to explain the properties of metals. One of the simplest models views the lattice positions of a metal lattice structure as being occupied by *positive ions* (nuclei plus core electrons). Surrounding them is a "cloud" of electrons formed by the valence electrons, which extends throughout the entire solid (see Figure 12.53). The electrons in this cloud belong to no single positive ion, but rather to the metal as a whole. Because the electrons aren't localized on any one atom, they are free to move easily, which accounts for the high electrical conductivity of metals. The electrons can also carry kinetic energy rapidly through the solid, so metals are also good conductors of heat. This model explains the luster of metals, too. When light



Positive ions from the metal
Electron cloud that doesn't belong to any one metal ion

Figure 12.53 | **The "electron sea" model of a metallic crystal.** In this highly simplified view of a metallic solid, metal atoms lose valence electrons to the solid as a whole and exist as positive ions surrounded by a mobile "sea" of electrons.

shines on the metal, the loosely held electrons vibrate easily and readily re-emit the light with essentially the same frequency and intensity.

Some metals, like tungsten, have very high melting points. Others, such as sodium (mp = 97.8 °C) and mercury (mp = −38.83 °C), have quite low melting points. To some extent, the melting point depends on the charge of the positive ions in the metallic crystal. The Group 1A metals have just one valence electron, so their cores are cations with a 1+ charge, which are only weakly attracted to the "electron sea" that surrounds them. Atoms of the Group 2A metals, however, form ions with a 2+ charge. These are attracted more strongly to the surrounding electron sea, so the Group 2A metals have higher melting points than their neighbors in Group 1A. Metals with very high melting points, like tungsten, must have very strong attractions between their atoms and between the atoms and the electron sea, which suggests that there probably is some covalent bonding between them as well.

The different ways of classifying crystals and a summary of their general properties are given in Table 12.7.

TOOLS

Properties of crystal types

Table 12.7 **Types of Crystals**

Crystal Type	Particles Occupying Lattice Sites	Type of Attractive Force	Typical Examples	Typical Properties
Ionic	Positive and negative ions	Attractions between ions of opposite charge	NaCl, $CaCl_2$, $NaNO_3$	Relatively hard; brittle; high melting points; nonconductors of electricity as solids, but conduct when melted
Molecular	Atoms or molecules	Dipole–dipole attractions, London forces, hydrogen bonding	HCl, SO_2, N_2, Ar, CH_4, H_2O	Soft; low melting points; nonconductors of electricity in both solid and liquid states
Covalent (network)	Atoms	Covalent bonds between atoms	Diamond, SiC (silicon carbide), SiO_2 (sand, quartz)	Very hard; very high melting points; nonconductors of electricity
Metallic	Positive ions	Attractions between positive ions and an electron cloud that extends throughout the crystal	Cu, Ag, Fe, Na, Hg	Range from very hard to very soft; melting points range from high to low; conduct electricity in both solid and liquid states; have characteristic luster

Example 12.8
Identifying Crystal Types from Physical Properties

The metal osmium, Os, forms an oxide with the formula OsO_4. The soft crystals of OsO_4 melt at 40 °C, and the resulting liquid does not conduct electricity. To which crystal type does solid OsO_4 probably belong?

■ **Analysis:** You might be tempted to suggest that the compound is ionic simply because it is formed from a metal and a nonmetal. However, the properties of the compound are inconsistent with it being ionic. Therefore, we have to consider that there may be exceptions to the generalization discussed earlier about metal–nonmetal compounds. If so, what do the properties of OsO_4 suggest about its crystal type?

■ **Assembling the Tools:** Table 12.7 lists the properties of the different types of crystals. We can use this information in the table as a tool to solve this problem.

■ **Solution:** The characteristics of the OsO_4 crystals—softness and a low melting point—suggest that solid OsO_4 is a molecular solid and that it contains molecules of OsO_4. This is further supported by the fact that liquid OsO_4 does not conduct electricity, which is evidence for the lack of ions in the liquid.

■ **Is the Answer Reasonable?** There's not much we can do to check ourselves here except to review our analysis.

Practice Exercises

12.19 | Stearic acid is an organic acid that has a chain of 18 carbon atoms. It is a soft solid with a melting point of 70 °C. What crystal type best describes this compound? (*Hint:* Determine the dominant attractive forces that cause stearic acid to be a solid at room temperature.)

12.20 | Boron nitride, which has the empirical formula BN, melts at 2730 °C and is almost as hard as a diamond. What is the probable crystal type for this compound?

12.21 | Crystals of elemental sulfur are easily crushed and melt at 113 °C to give a clear yellow liquid that does not conduct electricity. What is the probable crystal type for solid sulfur?

CHEMISTRY OUTSIDE THE CLASSROOM | 12.2

Giant Crystals

The most common crystals that we use are salt crystals in our salt shakers. These crystals are less than a millimeter on an edge. However, in 2000, giant gypsum crystals were discovered by miners 300 meters below the Naica mountain in Mexico. These crystals measure up to 11 meters in length and can weigh up to 55 tons. Originally, the crystals were submerged, undisturbed, in an aqueous solution of calcium sulfate at 58 °C, which allowed them to slowly grow into these gigantic forms over many thousands of years. Gypsum is unusual in that it becomes less soluble as the temperature increases. If the temperature had been cooler, the crystals would have been smaller, because more calcium sulfate would have been in solution. Since the solution was kept at such a warm temperature, however, the crystals were able to grow larger and larger as more calcium sulfate precipitated.

Another interesting aspect of this cave is that while the temperature is 58 °C, the air is between 90 and 100% humidity. Under these conditions, a person would be one of the coolest objects in the cave, since body temperature is 37 °C. Breathing this air would cause the water in the air to condense in the lungs as it cooled inside the body. A person could only stay in the cave for 10 minutes at a time without drowning.

(NG Image Collection)

Summary

Physical Properties: Gases, Liquids, and Solids. Gases expand to fill the entire volume of a container. Liquids and solids retain a constant volume if transferred from one container to another. Solids also retain a constant shape. These characteristics are related to how tightly packed the particles are and to the relative strengths of the intermolecular attractions in the different states of matter. Most physical properties depend primarily on intermolecular attractions. In gases, these attractions are weak because the molecules are so far apart. They are much stronger in liquids and solids, where the particles are packed together tightly.

Intermolecular Attractions. Polar molecules attract each other by **dipole–dipole attractions**, which arise because the positive end of one dipole attracts the negative end of another. Nonpolar molecules are attracted to each other by **London dispersion forces**, which are **instantaneous dipole–induced dipole attractions**. London forces are present between all particles, including atoms, polar and nonpolar molecules, and ions. Among different substances, London forces increase with an increase in the size of a particle's electron cloud; they also increase with increasing chain length among molecules such as the hydrocarbons. Compact molecules experience weaker London forces than similar long-chain molecules. For large molecules, the cumulative effect of large numbers of weak London force interactions can be quite strong and outweigh other intermolecular attractions. **Hydrogen bonding**, a special case of dipole–dipole attractions, occurs between molecules in which hydrogen is covalently bonded to a small, very electronegative atom—principally, nitrogen, oxygen, or fluorine. Hydrogen bonding is much stronger than the other types of intermolecular attractions. **Ion–dipole attractions** occur when ions interact with polar substances. **Ion–induced dipole attractions** result when an ion creates a dipole in a neighboring nonpolar molecule or ion.

General Properties of Liquids and Solids. Properties that depend mostly on the closeness of the packing of particles are **compressibility** (or the opposite, incompressibility) and **diffusion**. Diffusion is slow in liquids and almost nonexistent in solids at room temperature. Properties that depend mostly on the strengths of intermolecular attractions are the **retention of volume and shape, surface tension**, and the **ease of evaporation. Surface tension** is related to the energy needed to expand a liquid's surface area. A liquid can **wet** a surface if its molecules are attracted to the surface about as strongly as they are attracted to each other. The **evaporation** of liquids and solids is endothermic and produces a cooling effect. The overall rate of evaporation increases with increasing surface area. The rate of evaporation from a given surface area of a liquid increases with increasing temperature and with decreasing intermolecular attractions. The evaporation of a solid is called **sublimation**.

Changes of State. Changes from one physical state to another—namely, **fusion**, freezing, **vaporization, condensation, deposition**, or **sublimation**—can occur as dynamic equilibria. In a **dynamic equilibrium**, opposing processes occur continually at equal rates, so over time there is no apparent change in the composition of the system. For liquids and solids, equilibria are established when vaporization occurs in a sealed container. A solid is in equilibrium with its liquid at the melting point.

Vapor Pressures. When the rates of evaporation and condensation of a liquid are equal, the vapor above the liquid exerts a pressure called the **equilibrium vapor pressure** (or more commonly, just the **vapor pressure**). The vapor pressure is controlled by the rate of evaporation *per unit surface area.* When the intermolecular attractive forces are large, the rate of evaporation is small and the vapor pressure is small. Vapor pressure increases with increasing temperature because the rate of evaporation increases as the temperature rises. The vapor pressure is independent of the *total* surface area of the liquid. Solids have vapor pressures just as liquids do.

Boiling Point. A substance boils when its vapor pressure equals the prevailing atmospheric pressure. The **normal boiling point** of a liquid is the temperature at which its vapor pressure equals 1 atm. Substances with high boiling points have strong intermolecular attractions.

Energy Changes Associated with Changes of State. On a **heating curve**, flat portions correspond to phase changes in which the heat added changes the potential energies of the particles without changing their average kinetic energy. On a **cooling curve, supercooling** sometimes occurs when the temperature of the liquid drops below the freezing point of the substance. **Superheating** occurs when the temperature of a liquid rises above its boiling point. The enthalpy changes for melting, the vaporization of a liquid, and sublimation are the **molar heat of fusion**, ΔH_{fusion}, the **molar heat of vaporization**, $\Delta H_{\text{vaporization}}$, and the **molar heat of sublimation**, $\Delta H_{\text{sublimation}}$, respectively. They are all endothermic and are related in size as follows: $\Delta H_{\text{fusion}} < \Delta H_{\text{vaporization}} < \Delta H_{\text{sublimation}}$. The sizes of these enthalpy changes are large for substances with strong intermolecular attractive forces.

Heats of Vaporization and the Clausius–Claperyon Equation. The heat of vaporization of a substance is related to the variation of the vapor pressure with changes in temperature. This is a linear relationship between the natural log of the pressure and the reciprocal of the temperature as given in the equation

$$\ln \frac{P_1}{P_2} = \frac{\Delta H_{\text{vap}}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$

Le Châtelier's Principle. When the equilibrium in a system is upset by a disturbance, the system changes in a direction that minimizes the disturbance and, if possible, brings the system back to equilibrium. By this principle, we find that raising the temperature favors an endothermic change. Decreasing the volume favors a change toward a more dense phase.

Phase Diagrams. Temperatures and pressures at which equilibria can exist between phases are depicted graphically in a **phase diagram**. The three equilibrium lines intersect at the **triple point**. The liquid–vapor line terminates at the **critical point**. At the **critical temperature**, a liquid has a vapor pressure equal to its **critical pressure**. Above the critical temperature a liquid phase cannot be formed; the single phase that exists is called a **supercritical fluid**. The equilibrium lines also divide a phase diagram into temperature–pressure regions in which a substance can exist in just a single phase. Water is different from most substances in that its melting point decreases with increasing pressure.

Crystalline Solids. Crystalline solids have highly ordered arrangements of particles within them, which can be described in terms of repeating three-dimensional arrays of points called **lattices**. The simplest portion of a lattice is its **unit cell**. Many structures can be described with the same lattice by associating different units (i.e., atoms, molecules, or ions) to lattice points and by changing the dimensions of the unit cell. All crystals can be classified into one of the 14 different lattice types shown in Table 12.6. Three cubic unit cells are possible—**simple cubic, face-centered cubic**, and **body-centered cubic**. Sodium chloride and many other alkali metal halides crystallize in the **rock salt structure**, which contains four formula units per unit cell. Two modes of closest packing of atoms are **cubic closest packing (ccp)** and **hexagonal closest packing (hcp)**. The ccp structure has an A-B-C-A-B-C- . . . alternating stacking of layers of spheres; the hcp structure has an A-B-A-B- . . . stacking of layers. **Amorphous** solids lack the internal structure of crystalline solids. Glass is an amorphous solid and is sometimes called a **supercooled liquid**.

X-Ray Diffraction. Information about crystal structures is obtained experimentally from **X-ray diffraction patterns** produced by the constructive and destructive interference of X rays scattered by atoms. Distances between planes of atoms in a crystal can be calculated by the Bragg equation, $n\lambda = 2d \sin \theta$, where n is a whole number, λ is the wavelength of the X rays, d is the distance between planes of atoms producing the diffracted beam, and θ is the angle at which the diffracted X-ray beam emerges relative to the planes of atoms producing the diffracted beam.

Crystal Types. Crystals can be divided into four general types: **ionic, molecular, covalent**, and **metallic**. Their properties depend on the kinds of particles within the lattice and on the attractions between the particles, as summarized in Table 12.7.

Tools for Problem Solving

The following tools were introduced in this chapter. Study them carefully so you can select the appropriate tool when needed.

Types of intermolecular forces (page 535)

London forces, dipole–dipole interactions, and hydrogen bonding are the three intermolecular forces that are responsible for the intermolecular attractions between molecules in the liquid and solid states. Ion–dipole and ion–induced dipole attractions are the interactions of ions with polar and nonpolar substances. See the summary table on page 535. From molecular structure, we can determine whether a molecule is polar or not and whether it has N—H or O—H bonds. This lets us predict and compare the strengths of intermolecular attractions.

Factors that affect the rate of evaporation: temperature and intermolecular forces (page 542)

As the temperature of a substance increases, the average kinetic energy of the molecules in the substance increases, and the rate of evaporation increases. The stronger the intermolecular forces, the slower is the rate of evaporation.

Factors that affect vapor pressure (page 545)

The two factors that affect the vapor pressure of a substance are the temperature of the system and the intermolecular forces. Therefore, we can compare the strengths of the intermolecular forces based on the relative magnitudes of the vapor pressures at a given temperature. The amount of substance present and the volume of the space for the vapor do not affect the vapor pressure as long as some of the liquid or solid is present.

Boiling points and intermolecular forces (page 547)

These allow us to compare the strengths of intermolecular forces in substances based on their boiling points. The normal boiling point of a liquid is the boiling point of the liquid at 1 atm.

Enthalpy changes during phase changes (page 549)

These changes allow us to compare the strengths of intermolecular forces in substances based on relative values of $\Delta H_{\text{vaporization}}$ and $\Delta H_{\text{sublimation}}$.

Heat of fusion (page 550)
The amount of heat required to melt a given amount of a substance is given by

$$q = n \times \Delta H_{\text{fusion}}$$

Clausius–Clapeyron equation (page 553)
The relationship between vapor pressure, heats of vaporization, and temperature is

$$\ln \frac{P_1}{P_2} = \frac{\Delta H_{\text{vap}}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$

Le Châtelier's principle (page 555)
Le Châtelier's principle enables us to predict the direction in which the position of equilibrium is shifted when a dynamic equilibrium is upset by a disturbance. You should be able to predict how the position of equilibrium between phases is affected by temperature and pressure changes.

Phase diagrams (page 556)
We use a phase diagram to identify temperatures and pressures at which equilibrium can exist between phases of a substance, and to identify conditions under which only a single phase can exist.

Cubic unit cells (page 562)
The three basic cubic lattice structures are simple cubic, face-centered cubic, and body-centered cubic. By knowing the arrangements of atoms in these unit cells, we can use the dimensions of the unit cell to calculate atomic radii and other properties.

Counting atoms in unit cells (page 562)
The stoichiometry of the atoms in the unit cell must equal the stoichiometry of the compound. The number of atoms in the unit cell can be counted by adding up the parts of the atoms that are contained in the unit cell: $\frac{1}{8}$ for an atom in a corner, $\frac{1}{4}$ for an atom on an edge, $\frac{1}{2}$ for an atom in a face, and 1 for an atom wholly in the unit cell.

Bragg equation (page 569)

$$n\lambda = 2d \sin \theta$$

Using the wavelength of X rays and the angles at which X rays are diffracted from a crystal, the distances between planes of atoms can be calculated.

Properties of crystal types (page 573)
By examining certain physical properties of a solid (i.e., the hardness, melting point, and electrical conductivity in the solid and liquid states), we can often predict the nature of the particles that occupy lattice sites in the solid and the kinds of attractive forces between them.

PLUS = *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com.** **ILW** = An Interactive Learningware solution is available for this problem. **OH** = An Office Hour video is available for this problem. Review Problems are presented in pairs separated by blue rules. Answers to problems whose numbers appear in blue are given in Appendix B. More challenging problems are marked with an asterisk *.

Review Questions

Comparisons among the States of Matter

12.1 Why are the intermolecular attractive forces stronger in liquids and solids than they are in gases?

12.2 Compare the behavior of gases, liquids, and solids when they are transferred from one container to another.

12.3 For a given substance, how do the intermolecular attractive forces compare in its gaseous, liquid, and solid states?

12.4 Why do intermolecular attractions weaken as the distances between the molecules increase?

Intermolecular Attractions

12.5 Which kinds of attractive forces, intermolecular or intramolecular, are responsible for chemical properties? Which kind are responsible for physical properties?

12.6 What are *London forces*? How are they affected by the sizes of the atoms in a molecule? How are they affected by the number of atoms in a molecule? How are they affected by the shape of a molecule?

12.7 Define *polarizability*. How does this property affect the strengths of London forces?

12.8 Describe *dipole–dipole attractions*.

12.9 Which nonmetals, besides hydrogen, are most often involved in hydrogen bonding? Why these elements and not others?

12.10 Which is expected to have the higher boiling point, C_8H_{18} or C_4H_{10}? Explain your choice.

12.11 Ethanol and dimethyl ether have the same molecular formula, C_2H_6O. Ethanol boils at 78.4 °C, whereas dimethyl ether boils at −23.7 °C. Their structural formulas are

CH_3CH_2OH
ethanol

CH_3OCH_3
dimethyl ether

Explain why the boiling point of the ether is so much lower than the boiling point of ethanol.

12.12 How do the strengths of covalent bonds and dipole–dipole attractions compare? How do the strengths of ordinary dipole–dipole attractions compare with the strengths of hydrogen bonds?

12.13 Which would give a stronger ion–dipole interaction with water molecules: Al^{3+} or Na^+?

12.14 For each pair, which ion produces the stronger ion-induced dipole attractions with oxygen molecules?

(a) O^{2-} or S^{2-}, **(b)** Mg^{2+} or Al^{3+}

General Properties of Liquids and Solids

12.15 Name two physical properties of liquids and solids that are controlled primarily by how tightly packed the particles are. Name three that are controlled mostly by the strengths of the intermolecular attractions.

12.16 Why does diffusion occur more slowly in liquids than in gases? Why does diffusion occur extremely slowly in solids?

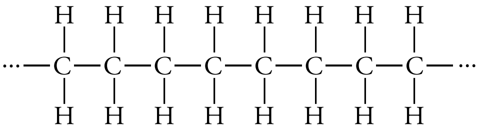
12.17 On the basis of kinetic theory, would you expect the rate of diffusion in a liquid to increase or decrease as the temperature is increased? Explain your answer.

12.18 What is *surface tension*? Why do molecules at the surface of a liquid behave differently from those within the interior?

12.19 Which liquid is expected to have the larger surface tension at a given temperature, CCl_4 or H_2O? Explain your answer.

12.20 What does *wetting* of a surface mean? What is a *surfactant?* What is its purpose and how does it function?

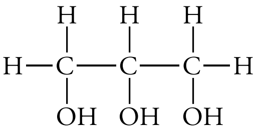
12.21 Polyethylene plastic consists of long chains of carbon atoms, each of which is also bonded to hydrogens, as shown in the following structure:



$$\begin{array}{ccccccccccccccccc}
 & H & & H & & H & & H & & H & & H & & H & & H & \\
 & | & & | & & | & & | & & | & & | & & | & & | & \\
\cdots- & C & - & C & - & C & - & C & - & C & - & C & - & C & - & C & -\cdots \\
 & | & & | & & | & & | & & | & & | & & | & & | & \\
 & H & & H & & H & & H & & H & & H & & H & & H &
\end{array}$$

Water forms beads when placed on a polyethylene surface. Why?

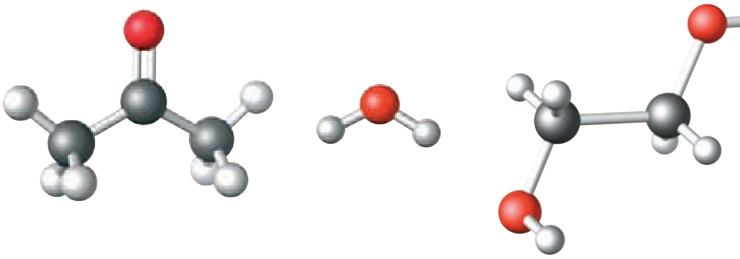
12.22 The structural formula for glycerol is



$$\begin{array}{ccccccccc}
 & & H & & H & & H & & \\
 & & | & & | & & | & & \\
H & - & C & - & C & - & C & - & H \\
 & & | & & | & & | & & \\
 & & OH & & OH & & OH & &
\end{array}$$

Would you expect this liquid to wet glass surfaces? Explain your answer.

12.23 Acetone (CH_3COCH_3), water, and ethylene glycol (CH_2OHCH_2OH) are listed here, and shown below in ball-and-stick figures, in the order of increasing viscosity for these three compounds. Why is this the correct order?



12.24 On the basis of what happens on the molecular level, why does evaporation lower the temperature of a liquid?

12.25 On the basis of the distribution of kinetic energies of the molecules of a liquid, explain why increasing the liquid's temperature increases the rate of evaporation.

12.26 How is the rate of evaporation of a liquid affected by increasing the surface area of the liquid? How is the rate of evaporation affected by the strengths of intermolecular attractive forces?

12.27 During the cold winter months, snow often disappears gradually without melting. How is this possible? What is the name of the process responsible for this phenomenon?

Changes of State and Equilibrium

12.28 What terms do we use to describe the following changes of state?

(a) solid → gas,
(b) gas → solid,
(c) liquid → gas,
(d) gas → liquid,
(e) solid → liquid,
(f) liquid → solid

12.29 When a molecule escapes from the surface of a liquid by evaporation, it has a kinetic energy that's much larger than the average KE. Why is it likely that after being in the vapor for a while its kinetic energy will be much less? If this molecule collides with the surface of the liquid, is it likely to bounce out again?

12.30 Why does a molecule of a vapor that collides with the surface of a liquid tend to be captured by the liquid, even if the incoming molecule has a large kinetic energy?

12.31 When an equilibrium is established in the evaporation of a liquid into a sealed container, we refer to it as a *dynamic equilibrium*. Why?

12.32 Viewed at the molecular level, what is happening when a dynamic equilibrium is established between the liquid and solid forms of a substance? What is the temperature called at which there is an equilibrium between a liquid and a solid?

12.33 Is it possible to establish an equilibrium between a solid and its vapor? Explain.

Vapor Pressure

12.34 Define *equilibrium vapor pressure.* Why do we call the equilibrium involved a *dynamic equilibrium*?

12.35 Explain why changing the volume of a container in which there is a liquid–vapor equilibrium has no effect on the equilibrium vapor pressure.

12.36 Why doesn't a change in the surface area of a liquid cause a change in the equilibrium vapor pressure?

12.37 What effect does increasing the temperature have on the equilibrium vapor pressure of a liquid? Why?

12.38 Why does moisture condense on the outside of a cool glass of water in the summertime?

12.39 Why do we feel more uncomfortable in humid air at 90 °F than in dry air at 90 °F?

Boiling Points of Liquids

12.40 Define *boiling point* and *normal boiling point.*

12.41 Why does the boiling point vary with atmospheric pressure?

12.42 Mt. Kilimanjaro in Tanzania is the tallest peak in Africa (19,340 ft). The normal barometric pressure at the top of this mountain is about 345 torr. At what Celsius temperature would water be expected to boil there? (See Figure 12.29.)

12.43 When liquid ethanol begins to boil, what is present inside the bubbles that form?

12.44 The radiator cap of an automobile engine is designed to maintain a pressure of approximately 15 lb/in.^{2} above normal atmospheric pressure. How does this help prevent the engine from "boiling over" in hot weather?

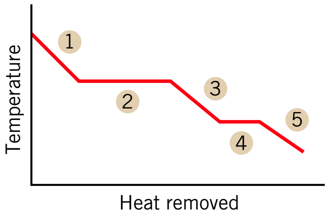
12.45 Butane, C_4H_{10}, has a boiling point of -0.5 °C (which is 31 °F). Despite this, liquid butane can be seen sloshing about inside a typical butane lighter, even at room temperature. Why isn't the butane boiling inside the lighter at room temperature?

12.46 Why does H_2S have a lower boiling point than H_2Se? Why does H_2O have a much higher boiling point than H_2S?

12.47 An H—F bond is more polar than an O—H bond, so HF forms stronger hydrogen bonds than H_2O. Nevertheless, HF has a lower boiling point than H_2O. Explain why this is so.

Energy Changes that Accompany Changes of State

12.48 The following is a cooling curve for one mole of a substance:



(a) On which portions of this graph do we find the average kinetic energy of the molecules of the substance changing?

(b) On which portions of this graph is the amount of heat removed related primarily to a lowering of the potential energy of the molecules?

(c) Which portion of the graph corresponds to the release of the heat of vaporization?

(d) Which portion of the graph corresponds to the release of the heat of fusion?

(e) Which is larger: the heat of fusion or the heat of vaporization?

(f) On the graph, indicate the melting point of the solid.

(g) On the graph, indicate the boiling point of the liquid.

(h) On the drawing, indicate how supercooling of the liquid would affect the graph.

12.49 Why is $\Delta H_{\text{vaporization}}$ larger than ΔH_{fusion}? How does $\Delta H_{\text{sublimation}}$ compare with $\Delta H_{\text{vaporization}}$? Explain your answer.

12.50 Would the "heat of condensation," $\Delta H_{\text{condensation}}$, be exothermic or endothermic?

12.51 Hurricanes can travel for thousands of miles over warm water, but they rapidly lose their strength when they move over a large land mass or over cold water. Why?

12.52 Ethanol (grain alcohol) has a molar heat of vaporization of 39.3 kJ/mol. Ethyl acetate, a common solvent, has a molar heat of vaporization of 32.5 kJ/mol. Which of these substances has the larger intermolecular attractions?

12.53 A burn caused by steam is much more serious than one caused by the same amount of boiling water. Why?

12.54 Arrange the following substances in order of their increasing values of $\Delta H_{\text{vaporization}}$: **(a)** HF, **(b)** CH_4, **(c)** CF_4, **(d)** HCl.

Clausius–Clapeyron Equation

12.55 According to the Clausius–Clapeyron equation, how does the vapor pressure of a substance change as the temperature increases?

12.56 Why can't Celsius temperatures be used in the Clausius–Clapeyron equation?

Le Châtelier's Principle

12.57 State Le Châtelier's principle in your own words.

12.58 What do we mean by the *position of equilibrium*?

12.59 Use Le Châtelier's principle to predict the effect of adding heat in the equilibrium: solid + heat $\rightleftharpoons$ liquid.

12.60 Use Le Châtelier's principle to explain why lowering the temperature lowers the vapor pressure of a solid.

Phase Diagrams

12.61 For most substances, the solid is more dense than the liquid. Use Le Châtelier's principle to explain why the melting point of such substances should *increase* with increasing pressure. Sketch the phase diagram for such a substance, being sure to have the solid–liquid equilibrium line slope in the correct direction.

12.62 Define *critical temperature* and *critical pressure.*

12.63 What is a supercritical fluid? Why is supercritical CO_2 used to decaffeinate coffee?

12.64 What phases of a substance are in equilibrium at the triple point?

12.65 Why doesn't CO_2 have a normal boiling point?

12.66 At room temperature, hydrogen can be compressed to very high pressures without liquefying. On the other hand, butane becomes a liquid at high pressure (at room temperature). What does this tell us about the critical temperatures of hydrogen and butane?

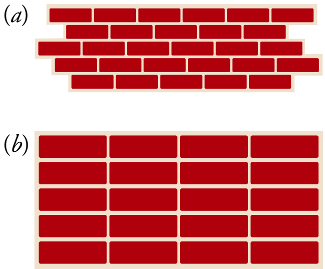
Crystalline Solids and X-Ray Diffraction

12.67 What is the difference between a crystalline solid and an amorphous solid?

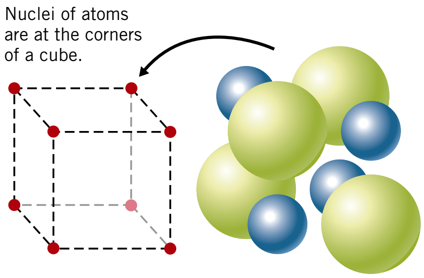
12.68 What is a *lattice*? What is a *unit cell*?

12.69 What relationship is there between a crystal lattice and its unit cell?

12.70 The diagrams that follow illustrate two typical arrangements of paving bricks in a patio or driveway. Sketch the unit cell that corresponds to each pattern of bricks.



12.71 The figure below illustrates the way the atoms of two different elements are packed in a certain solid. The nuclei occupy positions at the corners of a cube. Is this cube the unit cell for this substance? Explain your answer.



12.72 Make a sketch of a layer of sodium ions and chloride ions in a NaCl crystal. Indicate how the ions are arranged in a face-centered cubic pattern, regardless of whether we place lattice points at the Cl^- ions or the Na^+ ions.

12.73 How do the crystal structures of copper and gold differ? In what way are they similar? On the basis of the locations of the elements in the periodic table, what kind of crystal structure would you expect for silver?

12.74 What kind of lattice does zinc sulfide have? What kind of lattice does calcium fluoride have?

12.75 Only 14 different kinds of crystal lattices are possible. How can this be true, considering the fact that there are millions of different chemical compounds that are able to form crystals?

12.76 Write the Bragg equation and define the symbols.

12.77 Why can't $CaCl_2$ or $AlCl_3$ form crystals with the same structure as NaCl?

Crystal Types

12.78 What kinds of particles are located at the lattice sites in a metallic crystal?

12.79 What kinds of attractive forces exist between particles in **(a)** molecular crystals, **(b)** ionic crystals, and **(c)** covalent crystals?

12.80 Why are covalent crystals sometimes called *network solids*?

Amorphous Solids

12.81 What does the word *amorphous* mean?

12.82 What is an amorphous solid? Compare what happens when crystalline and amorphous solids are broken into pieces.

Review Problems

Intermolecular Attractions and Molecular Structure

12.83 Which liquid evaporates faster at 25 °C, diethyl ether (an anesthetic) or butanol (a solvent used in the preparation of shellac and varnishes)? Both have the molecular formula $C_4H_{10}O$, but their structural formulas are different:

$CH_3CH_2CH_2CH_2OH$ butanol

$CH_3CH_2-O-CH_2CH_3$ diethyl ether

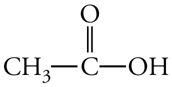
OH **12.84** Which compound should have the higher vapor pressure at 25 °C, butanol or diethyl ether? Which should have the higher boiling point?

12.85 What kinds of intermolecular attractive forces (i.e., dipole–dipole, London, and hydrogen bonding) are present in the following substances?

(a) HF **(b)** PCl_3 **(c)** SF_6 **(d)** SO_2

12.86 What kinds of intermolecular attractive forces are present in the following substances?

(a)



$CH_3-\overset{\overset{O}{\|}}{C}-OH$

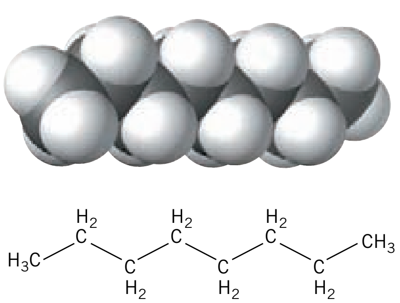
(b) H_2S

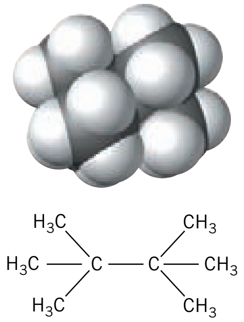
(c) SO_3 **(d)** CH_3NH_2

OH **12.87** Consider the compounds $CHCl_3$ (chloroform, an important solvent that was once used as an anesthetic) and $CHBr_3$ (bromoform, which has been used as a sedative). Compare the strengths of their dipole–dipole attractions and the strengths of their London forces. Their boiling points are 61 °C and 149 °C, respectively. For these compounds, which kinds of attractive forces (i.e., dipole–dipole or London) are more important in determining their boiling points? Justify your answer.

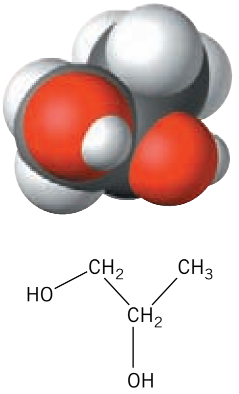
12.88 Carbon dioxide does not liquefy at atmospheric pressure, but instead forms a solid that sublimes at −78 °C. Nitrogen dioxide forms a liquid that boils at 21 °C at atmospheric pressure. How do these data support the statement that CO_2 is a linear molecule whereas NO_2 is nonlinear?

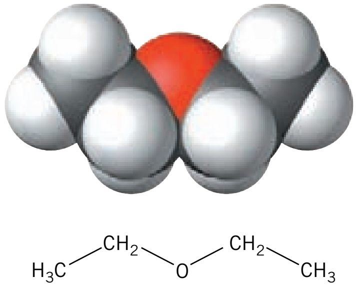
12.89 Which of the following isomers of octane should have the higher viscosity?





12.90 Which molecule below will wet a greasy glass surface more effectively, propylene glycol (left) or diethyl ether (right).





12.91 Which should have the higher boiling point, ethanol (CH_3CH_2OH, found in alcoholic beverages) or ethanethiol (CH_3CH_2SH, a foul-smelling liquid found in the urine of rabbits that have feasted on cabbage)?

12.92 How do the strengths of London forces compare in $CO_2(l)$ and $CS_2(l)$? Which of these is expected to have the higher boiling point? (Check your answer by referring to the *Handbook of Chemistry and Physics*, which is available in your school library.)

OH **12.93** The following are the vapor pressures of some relatively common chemicals measured at 20 °C:

Benzene, C_6H_6	80 torr
Acetic acid, $HC_2H_3O_2$	11.7 torr
Acetone, C_3H_6O	184.8 torr
Diethyl ether, $C_4H_{10}O$	442.2 torr
Water	17.5 torr

Arrange these substances in order of increasing intermolecular attractive forces.

12.94 The boiling points of some common substances are as follows:

Ethanol, C_2H_5OH	78.4 °C
Ethylene glycol, $C_2H_4(OH)_2$	197.2 °C
Water	100 °C
Diethyl ether, $C_4H_{10}O$	34.5 °C

Arrange these substances in order of increasing strengths of intermolecular attractions.

12.95 What intermolecular forces must the following substances overcome in the process of vaporization? **(a)** ethanol (C_2H_5OH), **(b)** acetonitrile (H_3CCN), and **(c)** sodium chloride (NaCl)?

12.96 What intermolecular attractions will be formed when the following substances condense from the gas phase? **(a)** hexane (C_6H_{14}), **(b)** acetone (H_3CCOCH_3), and **(c)** argon?

Energy Changes that Accompany Changes of State

OH **12.97** The molar heat of vaporization of water at 25 °C is +43.9 kJ/mol. How many kilojoules of heat would be required to vaporize 125 mL (0.125 kg) of water?

12.98 The molar heat of vaporization of acetone, C_3H_6O, is 30.3 kJ/mol at its boiling point. How many kilojoules of heat would be liberated by the condensation of 5.00 g of acetone?

12.99 Suppose 45.0 g of water at 85 °C is added to 105.0 g of ice at 0.0 °C. The molar heat of fusion of water is 6.01 kJ/mol, and the specific heat of water is 4.18 J/g °C. On the basis of these data, **(a)** what will be the final temperature of the mixture and **(b)** how many grams of ice will melt?

12.100 A cube of solid benzene (C_6H_6) at its melting point and weighing 10.0 g is placed in 10.0 g of water at 35 °C. Given that the heat of fusion of benzene is 9.92 kJ/mol, to what temperature will the water have cooled by the time all of the benzene has melted?

Heats of Vaporization

12.101 Mercury is used in barometers since it has such a low vapor pressure. The heat of vaporization of mercury is 59.2 kJ mol^{-1}, and its normal boiling point is 629.9 K. What is the vapor pressure of mercury at 298.2 K?

12.102 The heat of vaporization of water is 43.9 kJ mol^{-1}, and its normal boiling point is 373 K. Estimate the vapor pressure of water at 351 K.

12.103 We can determine the heat of vaporization by using the Clausius–Clapeyron equation if we know the vapor pressures of a substance at two different temperatures. Determine the heat of vaporization of diethyl ether if the vapor pressure is 1.0 mm Hg at −74.3 °C and 425 mm Hg at 18.7 °C.

12.104 If the vapor pressure of ethylene glycol is 7.23 mm Hg at 95.1 °C and 755 mm Hg at 197.1 °C, what is the heat of vaporization of ethylene glycol?

Phase Diagrams

12.105 Sketch the phase diagram for a substance that has a triple point at −15.0 °C and 0.30 atm, melts at −10.0 °C at 1 atm, and has a normal boiling point of 90 °C.

12.106 Based on the phase diagram sketched in Problem 12.105, below what pressure will the substance undergo sublimation? How does the density of the liquid compare with the density of the solid?

12.107 According to Figure 12.31, what phase(s) should exist for CO_2 at **(a)** −60 °C and 6 atm, **(b)** −60 °C and 2 atm, **(c)** −40 °C and 10 atm, and **(d)** −57 °C and 5.2 atm?

OH **12.108** Looking at the phase diagram for CO_2 (Figure 12.31), how can we tell that solid CO_2 is more dense than liquid CO_2?

Crystalline Solids and X-Ray Diffraction

12.109 How many zinc and sulfide ions are present in the unit cell of zinc sulfide? (See Figure 12.42.)

12.110 How many copper atoms are within the face-centered cubic unit cell of copper? (*Hint:* See Figure 12.38 and add up all of the *parts* of atoms in the fcc unit cell.)

OH ILW **12.111** The atomic radius of nickel is 1.24 Å. Nickel crystallizes in a face-centered cubic lattice. What is the length of the edge of the unit cell expressed in angstroms and in picometers?

12.112 Silver forms face-centered cubic crystals. The atomic radius of a silver atom is 144 pm. Draw the face of a unit cell with the nuclei of the silver atoms at the lattice points. The atoms are in contact along the diagonal. Calculate the length of an edge of this unit cell.

12.113 Potassium ions have a radius of 133 pm, and bromide ions have a radius of 195 pm. The crystal structure of potassium bromide is the same as for sodium chloride. Estimate the length of the edge of the unit cell in potassium bromide.

12.114 The unit cell edge in sodium chloride has a length of 564.0 pm. The sodium ion has a radius of 95 pm. What is the *diameter* of a chloride ion?

OH **12.115** Calculate the angles at which X rays of wavelength 229 pm will be observed to be defracted from crystal planes spaced **(a)** 1.0×10^3 pm apart and **(b)** 2.5×10^2 pm apart. Assume $n = 1$ for both calculations.

12.116 Calculate the interplanar spacings (in picometers) that correspond to defracted beams of X rays at $\theta = 20.0°$, 27.4°, and 35.8°, if the X rays have a wavelength of 141 pm. Assume that $n = 1$.

12.117 Cesium chloride forms a simple cubic lattice in which Cs^+ ions are at the corners and a Cl^- ion is in the center (see Figure 12.41). The cation–anion contact occurs along the *body diagonal* of the unit cell. (The body diagonal starts at one corner and then runs through the center of the cell to the opposite corner.). The length of the edge of the unit cell is 412.3 pm. The Cl^- ion has a radius of 181 pm. Calculate the radius of the Cs^+ ion.

12.118 Rubidium chloride has the rock salt structure. Cations and anions are in contact along the edge of the unit cell, which is 658 pm long. The radius of the chloride ion is 181 pm. What is the radius of the Rb^+ ion?

Crystal Types

12.119 Tin(IV) chloride, $SnCl_4$, has soft crystals with a melting point of −30.2 °C. The liquid is nonconducting. What type of crystal is formed by $SnCl_4$?

12.120 Elemental boron is a semiconductor, is very hard, and has a melting point of about 2250 °C. What type of crystal is formed by boron?

12.121 Columbium is another name for one of the elements. This element is shiny, soft, and ductile. It melts at 2468 °C, and the solid conducts electricity. What kind of solid does columbium form?

12.122 Elemental phosphorus consists of soft white "waxy" crystals that are easily crushed and melt at 44 °C. The solid does not conduct electricity. What type of crystal does phosphorus form?

12.123 Indicate which type of crystal (i.e., ionic, molecular, covalent, or metallic) each of the following would form when it solidifies: **(a)** Br_2, **(b)** LiF, **(c)** MgO, **(d)** Mo, **(e)** Si, **(f)** PH_3, and **(g)** NaOH.

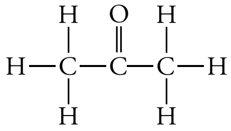
12.124 Indicate which type of crystal (i.e., ionic, molecular, covalent, or metallic) each of the following would form when it solidifies: **(a)** O_2, **(b)** H_2S, **(c)** Pt, **(d)** KCl, **(e)** Ge, **(f)** $Al_2(SO_4)_3$, and **(g)** Ne.

Additional Exercises

12.125 List *all* of the attractive forces that exist in solid Na_2SO_3.

OH **12.126** Calculate the mass of water vapor present in 10.0 L of air at 20.0 °C if the relative humidity is 75%.

12.127 Should acetone molecules be attracted to water molecules more strongly than to other acetone molecules? Explain your answer. The structure of acetone is as follows:



$$\mathrm{H{-}\underset{\underset{H}{|}}{\overset{\overset{H}{|}}{C}}{-}\overset{\overset{O}{\|}}{C}{-}\underset{\underset{H}{|}}{\overset{\overset{H}{|}}{C}}{-}H}$$

OH **12.128** Acetic acid has a heat of fusion of 10.8 kJ/mol and a heat of vaporization of 24.3 kJ/mol.

$$HC_2H_3O_2(s) \rightarrow HC_2H_3O_2(l) \qquad \Delta H_{\text{fusion}} = 10.8 \text{ kJ/mol}$$
$$HC_2H_3O_2(l) \rightarrow HC_2H_3O_2(g) \qquad \Delta H_{\text{vaporization}} = 24.3 \text{ kJ/mol}$$

Use Hess's law to estimate the value for the heat of sublimation of acetic acid in kilojoules per mole.

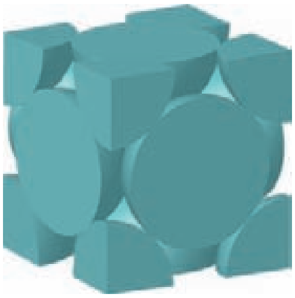
*__12.129__ Melting point is sometimes used as an indication of the extent of ionic bonding in a compound—the higher the melting point, the more ionic the substance. On this basis, oxides of metals seem to become less ionic as the charge on the metal ion increases. Thus, Cr_2O_3 has a melting point of 2266 °C whereas CrO_3 has a melting point of only 196 °C. The explanation often given is similar in some respects to explanations of the variations in the strengths of certain intermolecular attractions given in this chapter. Provide an explanation for the greater degree of electron sharing in CrO_3 as compared with Cr_2O_3.

*__12.130__ When warm, moist air sweeps in from the ocean and rises over a mountain range, it expands and cools. Explain how this cooling is related to the attractive forces between gas molecules. Why does this cause rain to form? When the air drops down the far side of the range, its pressure rises as it is compressed. Explain why this causes the air temperature to rise. How does the humidity of this air compare with the air that originally came in off the ocean? Now explain why the coast of California is lush farmland, whereas valleys (such as Death Valley) that lie to the east of the tall Sierra Nevada mountains are arid and dry.

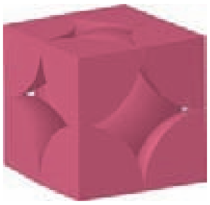
12.131 Gold crystallizes in a face-centered cubic lattice. The edge of the unit cell has a length of 407.86 pm. The density of gold is 19.31 g/cm^3. Use these data and the atomic mass of gold to calculate the value of Avogadro's number.

OH *__12.132__ Gold crystallizes with a face-centered cubic unit cell with an edge length of 407.86 pm. Calculate the atomic radius of gold in units of picometers.

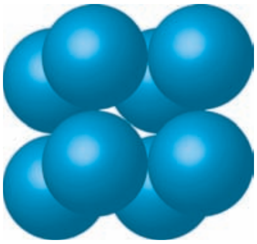
12.133 Identify the type of unit cell belonging to the following structures:



(*a*)



(*b*)



(*c*)

*__12.134__ Calculate the amount of empty space (in pm^3) in simple cubic, body-centered cubic, and face-centered cubic unit cells if the lattice points are occupied by identical atoms with a diameter of 1.00 pm. Which of these structures gives the most efficient packing of atoms?

12.135 Silver has an atomic radius of 144 pm. What would be the density of silver in g cm^{-3} if it were to crystallize in **(a)** a simple cubic lattice, **(b)** a body-centered cubic lattice, and **(c)** a face-centered cubic lattice? The actual density of silver is 10.6 g cm^{-3}. Which cubic lattice does silver have?

***12.136** Potassium chloride crystallizes with the rock salt structure. When bathed in X rays, the layers of atoms corresponding to the surfaces of the unit cell produce a diffracted beam of X rays at an angle of 12.8°. Calculate the density of KCl.

12.137 Why do clouds form when the humid air of a weather system called a *warm front* encounters the cool, relatively dry air of a *cold front*?

Multi-Concept Problems

***12.138** There are 270 Calories in a Hershey's® Milk Chocolate bar. If all of the energy in the bar were used to heat up 75 mL of ice at −25 °C, how hot would the water get? What state would the water be in? The following data might be useful: $\Delta H_{\text{vap}} = 43.9$ kJ/mol, $\Delta H_{\text{fusion}} = 6.02$ kJ/mol, $\Delta H_{\text{sublimation}} = 49.9$ kJ/mol, specific heat of ice = 2.05 J g^{-1} $°C^{-1}$, specific heat of water = 4.18 J g^{-1} $°C^{-1}$, and specific heat of steam = 2.08 J g^{-1} $°C^{-1}$. Assume that the specific heat of water does not change with temperature.

***12.139** Freeze-drying is a process used to preserve food. If strawberries are to be freeze-dried, then they would be frozen to −80 °C and subjected to a vacuum of 0.001 torr. As the water is removed, it is frozen to a cold surface in the freeze-drier. If 150 mL of water has to be removed from a batch of strawberries, how much energy would be required? What changes of state are taking place? At any given time, how much water is in the atmosphere if the volume of the freeze-drier is 5 liters? If it takes one hour to remove one mL of water, how long will it take to freeze-dry the strawberries?

Exercises in Critical Thinking

12.140 Supercritical CO_2 is used to decaffeinate coffee. Propose other uses for supercritical fluids.

12.141 Freshly precipitated crystals are usually very small. Over time the crystals tend to grow larger. How can we use the concept of dynamic equilibrium to explain this phenomenon?

12.142 What are some "everyday" applications of Le Châtelier's principle? For example, we turn up the heat in an oven to cook a meal faster.

12.143 Lubricants, oils, greases, and so on are very important in everyday life. Explain how a lubricant works in terms of intermolecular forces.

12.144 Galileo's thermometer is a tube of liquid that has brightly colored glass spheres that float or sink depending on the temperature. Using your knowledge from the past two chapters, explain all of the processes that are involved in this thermometer.

12.145 Use the Clausius–Clapeyron equation to plot the vapor pressure curve of a gas that has a heat of vaporization of 21.7 kJ mol^{-1} and a boiling point of 48 °C. Compare your results to the other vapor pressure curves in this chapter.

12.146 Will the near weightless environment of the international space station have any effect on intermolecular forces and chemical reactions? What types of chemical reactions may benefit from a weightless environment?

13

Mixtures at the Molecular Level: Properties of Solutions

Chapter Outline

13.1 | Intermolecular Forces and the Formation of Solutions

13.2 | Heats of Solution

13.3 | Solubility as a Function of Temperature

13.4 | Henry's Law

13.5 | Temperature-Independent Concentration Units

13.6 | Temperature-Dependent Concentration Units

13.7 | Colligative Properties

13.8 | Heterogeneous Mixtures

It is a relatively rare event to encounter a pure substance. Most things we see, purchase and use are mixtures that are either homogeneous or heterogeneous. On the grocery shelf in our photo, we observe an array of products that are obviously mixtures. Some of the bottles contain Italian salad dressing which is definitely a heterogeneous mixture. Other bottles contain mixtures that we can consider to be homogeneous solutions. In this chapter we expand upon the fundamental properties of pure gases, liquids and solids that we developed in Chapters 11 and 12 to consider what happens when we make homogeneous mixtures of these substances. Susan Kaprov

This Chapter in Context

In Chapter 5 we discussed solutions as a medium for carrying out chemical reactions. Our focus at that time was on the kinds of reactions that take place in solution, and in particular, those that occur when water is the solvent. In this chapter we will examine how the addition of a solute affects the physical properties of the mixture. In our daily lives we take advantage of many of these effects. For example, we add ethylene glycol (antifreeze) to the water in a car's radiator to protect it against freezing and overheating because water has a lower freezing point and higher boiling point when solutes are dissolved in it.

Here we will study not only aqueous solutions, but also solutions involving other solvents. We will concentrate on liquid solutions, although solutions can also be gaseous or solid. In fact, all gases mix completely at the molecular level, so the gas mixtures we examined in Chapter 11 were gaseous solutions. Solid solutions, called alloys, include such materials as brass and bronze. Other solid solutions include paraffin wax which is a mixture of long-chain hydrocarbons, and gemstones such as ruby, garnet, and jade, which are solid solutions where metal ions contribute to their distinctive colors.

Gemstones are examples of solid solutions

Gem Name	Mineral	Colorant Atom(s)
Ruby	Al_2O_3	Cr, Fe
Sapphire	Al_2O_3	Cr, Ti, Fe
Turquoise	$CuAl_6(PO_4)_4(OH)_8 \cdot 5H_2O$	Cu
Emerald	$Be_3Al_2Si_6O_{18}$	Cr, V
Lapis lazuli	$(Na, Ca)_8(AlSiO_4)_6(SO_4,S,Cl)_2$.	S
Jade	$NaAlSi_2O_6$	Cr
Amethyst	SiO_2	Mn
Tanzanite	$Ca_2Al_3(SiO_4)(Si_2O_7)O(OH)$	Cr
Malachite	$Cu_2CO_3(OH)_2$	Cu

13.1 | Intermolecular Forces and the Formation of Solutions

There is a wide variation in the ability of liquids to dissolve solutes. For example, water and gasoline do not dissolve in each other, but water and ethanol can be mixed in all proportions. Similarly, a salt such as potassium bromide will dissolve in water but not in liquid hydrocarbons such as paint thinner. To understand the reasons for these differences, we must examine the factors that drive solution formation as well as those that inhibit it.

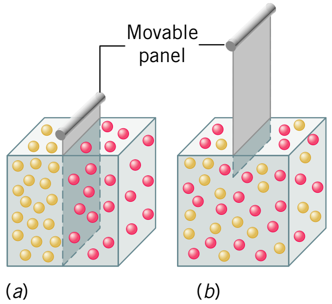


Figure 13.1 | **Mixing of gases.** When two gases, initially in separate compartments (*a*), suddenly find themselves in the same container (*b*), they mix spontaneously.

Gas Molecules and Spontaneous Mixing

In Chapter 11 you learned that all gases mix spontaneously to form homogeneous mixtures (i.e., solutions). If two gases are placed in separate compartments of a container such as that in Figure 13.1, and the movable partition between them is removed, the molecules will begin to intermingle. The random motions of the molecules will cause them to diffuse one into the other until a uniform mixture is achieved.

The spontaneous mixing of gases illustrates one of nature's strong "driving forces" for change. *A system, left to itself, will tend toward the most probable state.*[1] At the instant we remove the partition, the container holds two separate gas samples, in contact but unmixed. This represents a highly improbable state because of the natural motions of the molecules. The vastly more probable distribution is one in which the molecules are thoroughly mixed, so formation of the gaseous solution involves a transition from a highly improbable state to a highly probable one.

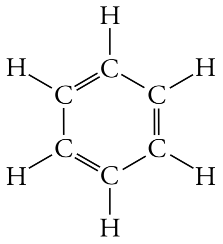
---

[1] In Chapter 19 this driving force will be called *entropy.*

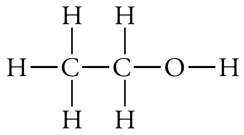
The drive to attain the most probable state favors the formation of *any* solution. What limits the ability of most substances to mix completely, however, are intermolecular forces of attraction. Such attractions are negligible in gases, so regardless of the chemical makeup of the molecules, the forces are unable to prevent them from mixing. That's why all gases spontaneously form solutions with each other. In liquids and solids, however, the situation is very different because intermolecular attractions are so much stronger.

Liquids Dissolving in Liquids

For a liquid solution to form, there must be a balance among the attractive forces so the natural tendency of particles to intermingle can proceed. In other words, the attractive forces between molecules within the solvent and between molecules within the solute must be about as strong as attractions between solute and solvent molecules. Let's look at two examples, mixtures of water with benzene and with ethanol.



benzene
(nonpolar)



ethanol
(contains a polar OH group)

Water and benzene (C_6H_6) are insoluble in each other. In water, there are strong hydrogen bonds between the molecules; in benzene the molecules attract each other by relatively weak London forces and are not able to form hydrogen bonds. Suppose that we did manage to disperse water molecules in benzene. As they move about, the water molecules would occasionally encounter each other. Because they attract each other so much more strongly than they attract benzene molecules, hydrogen bonds would cause water molecules to stick together at each such encounter. This would continue to happen until all the water was in a separate phase. Thus, a solution of water in benzene would not be stable and would gradually separate into two phases. We say water and benzene are **immiscible,** meaning they are mutually insoluble.

Water and ethanol (C_2H_5OH), on the other hand, are **miscible,** meaning that they are soluble in all proportions. This is because water and ethanol molecules can form hydrogen bonds with each other in mixtures that are nearly equivalent to those in the separate pure liquids (Figure 13.2). Mixing these molecules offers little resistance, so they are able to mingle relatively freely.

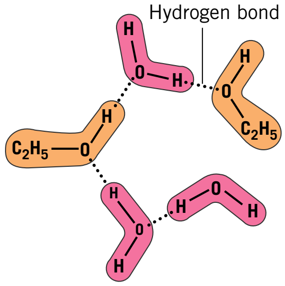


Figure 13.2 | **Hydrogen bonds in aqueous ethanol.** Ethanol molecules form hydrogen bonds (···) to water molecules.

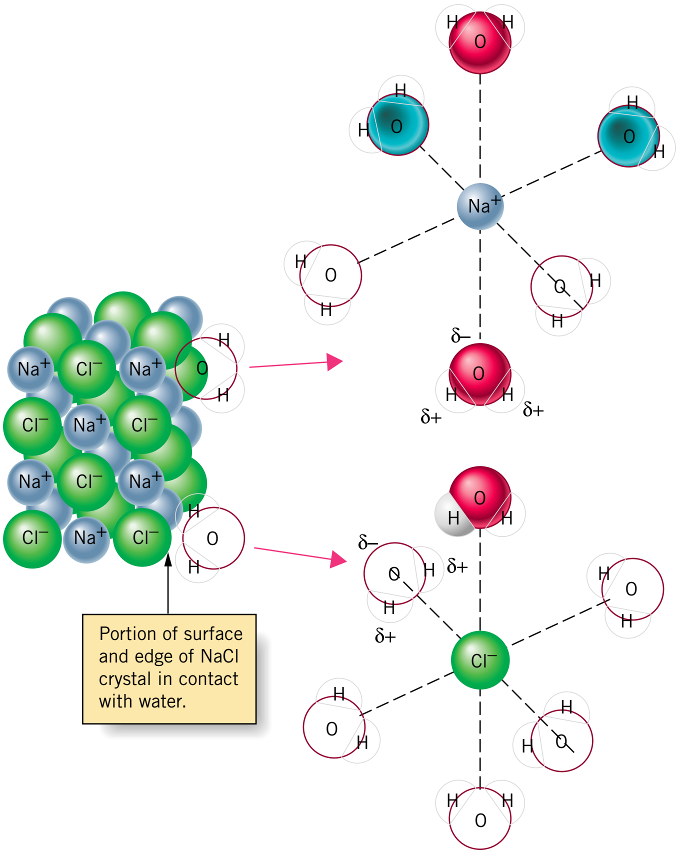
Like Dissolves Like Rule

Observations like those for benzene–water and ethanol–water mixtures led to a generalization often called the **"like dissolves like" rule:** when solute and solvent have molecules "like" each other in polarity, they tend to form a solution. When solute and solvent molecules are quite different in polarity, solutions of any appreciable concentration do not form. The rule has long enabled chemists to use chemical composition and molecular structure to predict the likelihood of two substances dissolving in each other.

TOOLS
"Like dissolves like" rule

The Solubility of Solids in Liquids

The "like dissolves like" principle also applies to the solubility of solids in liquid solvents. Polar solvents tend to dissolve polar and ionic compounds, whereas nonpolar solvents tend to dissolve nonpolar compounds.



Portion of surface and edge of NaCl crystal in contact with water.

Figure 13.3 | **Hydration of ions.** Hydration involves a complex redirection of forces of attraction and repulsion. Before this solution forms, water molecules are attracted only to each other, and Na$^+$ and Cl$^-$ ions have only each other to be attracted to in the crystal. In the solution, the ions have water molecules to take the places of their oppositely charged counterparts; in addition, water molecules are attracted to ions even more than they are to other water molecules.

■ Water molecules collide everywhere along the crystal surface, but *successful* collisions—those that dislodge ions—are more likely to occur at corners and edges.

Figure 13.3 depicts a section of a crystal of NaCl in contact with water. The dipoles of water molecules orient themselves so that the negative ends of some point toward Na$^+$ ions and the positive ends of others point at Cl$^-$ ions. In other words, *ion–dipole* attractions occur that tend to tug and pull ions from the crystal. At the corners and edges of the crystal, ions are held by fewer neighbors within the solid and so are more readily dislodged than those elsewhere on the crystal's surface. As water molecules dislodge these ions, new corners and edges are exposed, and the crystal continues to dissolve.

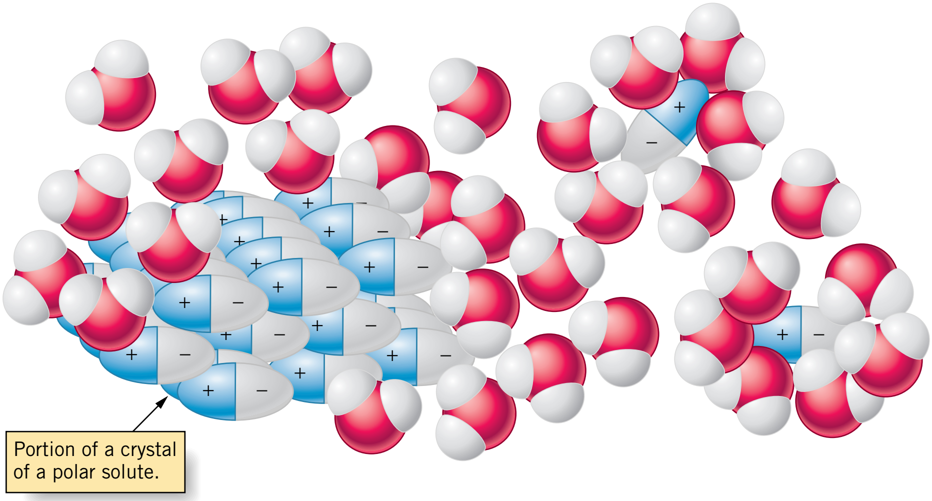
As they become free, the ions become completely surrounded by water molecules (also shown in Figure 13.3). The phenomenon is called the **hydration** of ions. The *general* term for the surrounding of a solute particle by solvent molecules is **solvation,** so hydration is just a special case of solvation. Ionic compounds are able to dissolve in water when the attractions between water dipoles and ions overcome the attractions of the ions for each other within the crystal.

Similar events explain why solids composed of polar molecules, like those of sugar, dissolve in water (see Figure 13.4). Attractions between the solvent and solute dipoles help to dislodge molecules from the crystal and bring them into solution. Again we see that "like dissolves like," because a polar solute dissolves in a polar solvent.

■ 
Sugar molecules such as this have polar OH groups that can form hydrogen bonds with water.

The same reasoning explains why nonpolar solids like wax are soluble in nonpolar solvents such as benzene. Wax is a solid mixture of long-chain hydrocarbons, held together by London forces. The attractions between benzene molecules are also London forces, of comparable strength, so molecules of the wax can easily be dispersed among those of the solvent.

When intermolecular attractive forces within solute and solvent are sufficiently different, the two do not form a solution. For example, ionic solids or very polar molecular solids (like sugar) have strong attractions between their particles that cannot be overcome by attractions to molecules of a nonpolar solvent such as benzene.



Portion of a crystal of a polar solute.
+
−

Figure 13.4 | **Hydration of a polar molecule.** A polar molecule of a molecular compound (such as the sugar glucose) can trade the forces of attraction it experiences for other molecules of its own kind for forces of attraction to molecules of water in an aqueous solution.

13.2 | Heats of Solution

Because intermolecular attractive forces are important when liquids and solids are involved, the formation of a solution is inevitably associated with energy exchanges. The total energy absorbed or released when a solute dissolves in a solvent at constant pressure to make a solution is called the *molar enthalpy of solution*,[2] or usually just the **heat of solution, ΔH_{soln}.**

Energy is required to separate the particles of solute and also those of the solvent and make them spread out to make room for each other. This step is *endothermic*, because we must overcome the attractions between molecules to spread the particles out. However, once the particles come back together as a *solution*, energy is released as the attractive forces between approaching solute and solvent particles decrease the system's potential energy. This is an *exothermic* change. The enthalpy of solution, ΔH_{soln}, is simply the net result of these two opposing enthalpy contributions.

Solutions of Solids in Liquids

Because enthalpy, H, is a state function, the magnitude of ΔH_{soln} doesn't depend on the path we take from the separated solute and solvent to the solution. For a solid dissolving in a liquid, it is convenient to imagine a two-step path.

Step 1. *Vaporize the solid to form individual solute particles.* The particles are molecules for molecular substances and ions for ionic compounds. The energy absorbed is equal in magnitude to, but with the opposite sign, as the lattice energy of the solid.

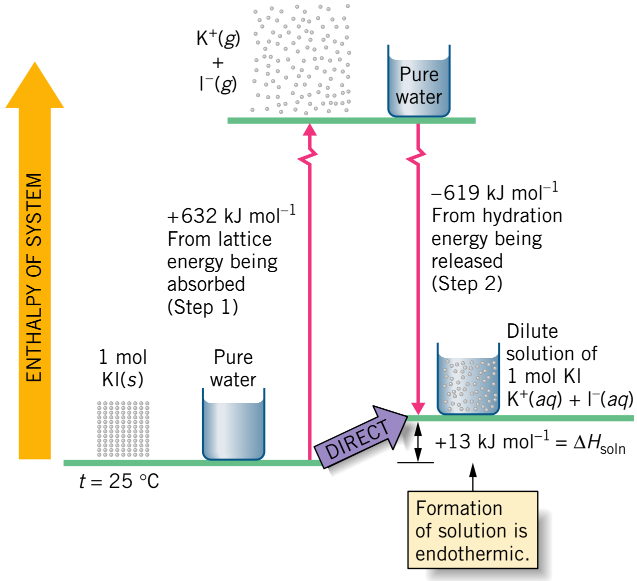
Step 2. *Bring the separated gaseous solute particles into the solvent to form the solution.* This step is exothermic, and the enthalpy change when the particles from one mole of solute are dissolved in the solvent is called the **solvation energy**. If the solvent is water, the solvation energy can also be called the **hydration energy**.

The enthalpy diagram showing these steps for potassium iodide is given in Figure 13.5. Step 1 corresponds to the negative of the lattice energy of KI, which is represented by the thermochemical equation.

$$\text{KI}(s) \longrightarrow \text{K}^+(g) + \text{I}^-(g) \qquad \Delta H = +632 \text{ kJ}$$

---

[2] As a solute is dissolved, the properties of the solvent change because of the presence of previously dissolved solute. Therefore, even if we know the molar heat of solution, we cannot precisely calculate the heat evolved when more, or less, than one mole of solute is dissolved in a liter of solvent.



ENTHALPY OF SYSTEM
$K^+(g)$ + $I^-(g)$
Pure water
+632 kJ mol^{-1} From lattice energy being absorbed (Step 1)
−619 kJ mol^{-1} From hydration energy being released (Step 2)
Dilute solution of 1 mol KI $K^+(aq) + I^-(aq)$
1 mol KI(s)
Pure water
DIRECT
+13 kJ mol^{-1} = ΔH_{soln}
t = 25 °C
Formation of solution is endothermic.

Figure 13.5 | **Enthalpy diagram for the heat of solution of one mole of potassium iodide.** Adding the negative of the lattice energy to the hydration energy gives a positive value for ΔH_{soln}, indicating the solution process is endothermic.

Step 2 corresponds to the hydration energy of gaseous K^+ and I^- ions.

$$K^+(g) + I^-(g) \longrightarrow K^+(aq) + I^-(aq) \qquad \Delta H = -619 \text{ kJ}$$

The *enthalpy of solution* is obtained from the sum of the equations for Steps 1 and 2 and is the enthalpy change when one mole of crystalline KI dissolves in water (corresponding to the direct path in Figure 13.5).

$$KI(s) \longrightarrow K^+(aq) + I^-(aq) \qquad \Delta H_{soln} = +13 \text{ kJ}$$

The value of ΔH_{soln} indicates that the solution process is endothermic for KI, in agreement with the observation that when KI is added to water and the mixture is stirred, it becomes cool as the KI dissolves.

Table 13.1 provides a comparison between values of ΔH_{soln} obtained by the method described above and values obtained by direct measurements. The agreement between calculated and measured values doesn't seem particularly impressive, but this is partly because lattice and hydration energies are not precisely known and partly because the model used in our analysis is evidently too simple. Notice, however, that when "theory" predicts relatively large heats of solution, the experimental values are also relatively large, and that both values have the same sign (except for NaBr). Notice also that the variations among the values follow the same trends when we compare the three chloride salts—LiCl, NaCl, and KCl—or the three bromide salts—LiBr, NaBr, and KBr.

■ Small percentage errors in very large numbers can cause huge uncertainties in the *differences* between such numbers.

Solutions of Liquids in Liquids

To consider heats of solution when liquids dissolve in liquids, it's useful to imagine a three-step path going from the initial to the final state (see Figure 13.6). We will designate one liquid as the solute and the other as the solvent.

Step 1. *Expand the solute liquid.* First, we imagine that the molecules of one liquid are moved apart just far enough to make room for molecules of the other liquid. Because we have to overcome forces of attraction, this step increases the system's potential energy and so is *endothermic*.

Table 13.1 **Lattice Energies, Hydration Energies, and Heats of Solution for Some Group 1A Metal Halides**

			ΔH_{soln}[a]	
Compound	**Lattice Energy (kJ mol^{-1})**	**Hydration Energy (kJ mol^{-1})**	**Calculated[b] ΔH_{soln} (kJ mol^{-1})**	**Measured ΔH_{soln} (kJ mol^{-1})**
LiCl	−853	−883	−30	−37.0
NaCl	−786	−770	+16	+3.9
KCl	−715	−686	+29	+17.2
LiBr	−807	−854	−47	−49.0
NaBr	−747	−741	+6	−0.602
KBr	−682	−657	+25	+19.9
KI	−649	−619	+30	+20.33

Solution

Figure 13.6 | **Enthalpy of solution for the mixing of two liquids.** To analyze the enthalpy change for the formation of a solution of two liquids, we can imagine the hypothetical steps shown here. **Step 1:** The molecules of the liquid designated as the solvent move apart slightly to make room for the solute molecules, an endothermic process. **Step 2:** The molecules of the solute are made to take up a larger volume to make room for the solvent molecules, which is also an endothermic change. **Step 3:** The expanded samples of solute and solvent spontaneously intermingle, their molecules also attracting each other, making the step exothermic.

Step 2. *Expand the solvent liquid.* The second step is like the first, but is done to the other liquid (the solvent). On an enthalpy diagram (Figure 13.7) we have climbed two energy steps and have both the solvent and the solute in their slightly "expanded" conditions.

Step 3. *Mix the expanded liquids.* The third step brings the molecules of the expanded solvent and solute together to form the solution. Because the molecules of the two liquids experience mutual forces of attraction, bringing them together lowers the system's potential energy, so Step 3 is exothermic. The value of ΔH_{soln} will, again, be the net energy change for these steps.

Ideal Solutions

The enthalpy diagram in Figure 13.7 shows the special case when the sum of the energy inputs for Steps 1 and 2 is equal to the energy released in Step 3, so the overall value of ΔH_{soln} is zero. This is very nearly the case when we make a solution of benzene and carbon tetrachloride. Attractive forces between molecules of benzene are almost exactly the same as those between molecules of CCl_4, or between molecules of benzene and those of CCl_4. If all such intermolecular forces were identical, the net ΔH_{soln} would be exactly zero, and the resulting solution would be called an **ideal solution**. Be sure to notice the difference between an *ideal solution* and an *ideal gas*. In an ideal gas, there are *no* attractive forces. In an ideal solution, there are attractive forces, but they are all the *same*.

For most liquids that are mutually soluble, ΔH_{soln} is not zero. Instead, heat is either given off or absorbed. For example, acetone and water are liquids that form a solution exothermically (ΔH_{soln} is negative.). With these liquids, the third step releases more energy

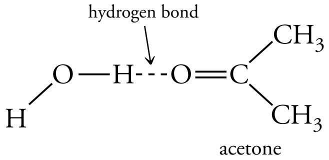
DIRECT FORMATION
For an ideal solution, $\Delta H_{\text{soln}} = 0$. $\Delta H_1 + \Delta H_2 = -\Delta H_3$

Figure 13.7 | **Enthalpy changes in the formation of an ideal solution.** The three-step and the direct-formation paths both start and end at the same place with the same enthalpy outcome. The sum of the positive ΔH values for the two endothermic steps, 1 and 2, numerically equals the negative ΔH value for the exothermic step, 3. The net ΔH for the formation of an ideal solution is therefore zero.

than the sum of the first two, chiefly because molecules of water and acetone attract each other more strongly than acetone molecules attract each other. This is because water molecules can form hydrogen bonds to acetone molecules in the solution, but acetone molecules cannot form hydrogen bonds to other acetone molecules in the pure liquid.



hydrogen bond
acetone

$CH_3CH_2CH_2CH_2CH_2CH_3$
hexane

Another pair of liquids, ethanol and hexane form a solution endothermically. In this case, the release of energy in the third step is not enough to compensate for the energy demands of Steps 1 and 2, so the solution cools as it forms. Since hydrogen-bonded ethanol molecules attract each other more strongly than they can attract hexane molecules, hexane molecules cannot push their way into ethanol without added energy to disrupt some of the hydrogen bonding between ethanol molecules.

Gas Solubility

Unlike solid and liquid solutes, only very weak attractions exist between gas molecules, so the energy required to "expand the solute" is negligible. The heat absorbed or released when a gas dissolves in a liquid has essentially two contributions, as shown in Figure 13.8:

1. *Energy is absorbed when "pockets" in the solvent are opened to hold gas molecules.* The solvent must be expanded slightly to accommodate the molecules of the gas. This requires a small energy input, since attractions between solvent molecules must be overcome. Water is a special case; it already contains open holes in its network of loose hydrogen bonds around room temperature. For water, very little energy is required to create pockets that can hold gas molecules.
2. *Energy is released when gas molecules occupy these pockets.* Intermolecular attractions between the gas molecules and the surrounding solvent molecules lower the total energy, and energy is released as heat. The stronger the attractions are, the more heat is released. Water is capable of forming hydrogen bonds with some gases, such as ammonia and hydrogen fluoride, while organic solvents often can't.

(b)

Figure 13.8 | **A molecular model of gas solubility.** (*a*) A gas dissolves in an organic solvent. Energy is absorbed to open "pockets" in the solvent that can hold the gas molecules. In the second step, energy is released when the gas molecules enter the pockets, where they are attracted to the solvent molecules. Here the solution process is shown to be endothermic. (*b*) At room temperature, water's loose network of hydrogen bonds already contains pockets that can accommodate gas molecules, so little energy is needed to prepare the solvent to accept the gas. In the second step, energy is released as the gas molecules take their places in the pockets, where they experience attractions to the water molecules. In this case, the solution process is exothermic.

A larger amount of heat is released when a gas molecule is placed in the pocket in water than when it is placed in organic solvents.

These factors lead to two generalizations. *First, heats of solution for gases in organic solvents are often endothermic* because the energy required to open up pockets is greater than the energy released by attractions formed between the gas and solvent molecules. *Second, heats of solution for gases in water are often exothermic* because water already contains pockets to hold the gas molecules, and energy is released when water and gas molecules attract each other.

13.3 | Solubility as a Function of Temperature

By "solubility" we mean the mass of solute that forms a *saturated* solution with a given mass of solvent at a specified temperature. The units often are grams of solute per 100 g of solvent. In such a solution there is a dynamic equilibrium between the undissolved solute and the solute dissolved in the solution, as shown in the equation below and in Figure 13.9.

$$\underset{\text{(Solute contacts the saturated solution.)}}{\text{solute}_{\text{undissolved}}} \rightleftharpoons \underset{\text{(Solute is in the saturated solution.)}}{\text{solute}_{\text{dissolved}}}$$

As long as the temperature is held constant, the concentration of the solute in the solution remains the same. However, if the temperature of the mixture changes, this equilibrium tends to be upset and either more solute will dissolve or some will precipitate. To analyze how temperature affects solubility we can use Le Châtelier's principle, which we introduced in Chapter 12. Recall that this principle tells us that if a system at equilibrium is disturbed, the system will change in a direction that counteracts the disturbance and returns the system to equilibrium (if it can).

To increase the temperature of a solution, heat (energy) is added. When solute dissolves in a solvent, heat is absorbed or evolved. As in Section 12.9, heat is the factor through which Le Châtelier's principle is applied. Let's consider a common situation in which energy is absorbed when the last few solute molecules are dissolved in preparing a saturated solution.[3]

$$\text{solute}_{\text{undissolved}} + \text{energy} \rightleftharpoons \text{solute}_{\text{dissolved}} \tag{13.1}$$

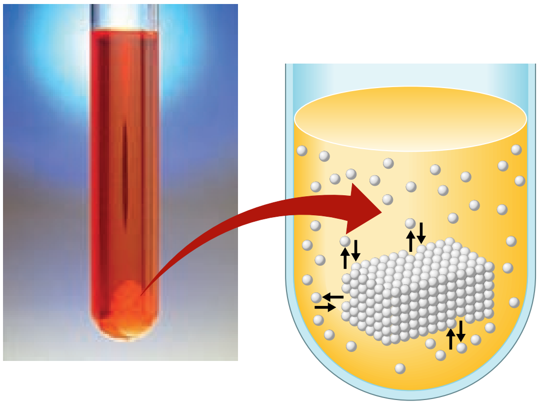

Figure 13.9 | **Molecular view of a saturated solution.** A saturated solution involves a dynamic equilibrium between the solid crystal and the dissolved particles. The arrows indicate that dissolving is occurring as rapidly as crystallization. *(Charles D. Winters/PhotoResearchers)*

---

[3] The heat of solution depends on the solute and the solvent. When preparing a solution, the added solute can be considered to be unchanging as it is added to the solution; however, the solvent does change. At the start, we add solute to pure solvent. Later in the process, we are adding solute to a mixture of solvent and solute. The solution process is one where solute is added to a continuously changing solvent. We find that the incremental heat of solution (i.e., heat evolved per gram of solute added) changes as the solvent changes and can even change from exothermic to endothermic. Interestingly, the incremental heats of solution of solutes added to a nearly saturated solution are almost all endothermic.

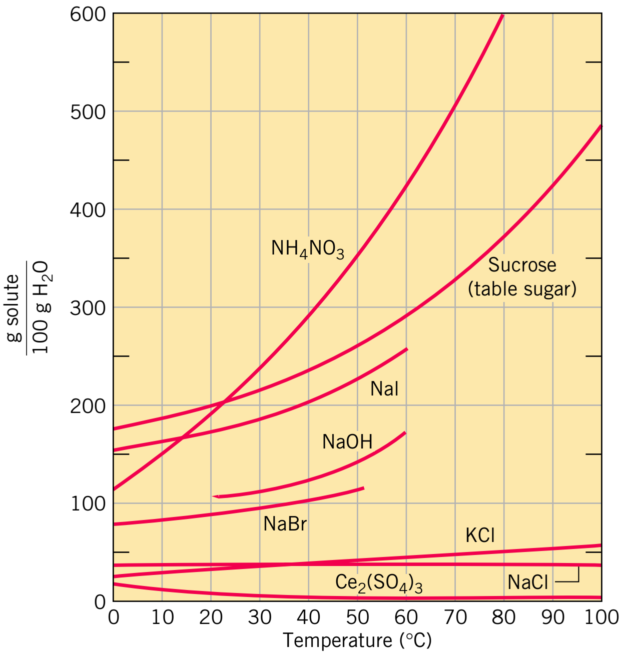

Figure 13.10 | **Solubility in water versus temperature for several substances.** Most substances become more soluble when the temperature of the solution is increased, but the amount of this increased solubility varies considerably.

According to Le Châtelier's principle, when we add heat energy to raise the temperature, the system responds by consuming some of the energy we've added. This causes the equilibrium in Equation 13.1 to "shift to the right." In other words, more solute is dissolved when equilibrium is reestablished. Thus, *when the solution process is endothermic (and it usually is endothermic near the saturation point), raising the temperature will increase the solubility of the solute.* This is a common situation for solids dissolving in liquid solvents. How much the solubility is affected by temperature varies widely, as seen in Figure 13.10.

Some solutes, such as cerium(III) sulfate, $Ce_2(SO_4)_3$, become *less* soluble with increasing temperature (Figure 13.10). Energy must be *released* from a saturated solution of $Ce_2(SO_4)_3$ to make more solute dissolve. For its equilibrium equation, we must show "energy" on the right side because heat is released.

$$\text{solute}_{\text{undissolved}} \rightleftharpoons \text{solute}_{\text{dissolved}} + \text{energy} \qquad \textbf{(13.2)}$$

Raising the temperature by adding heat causes dissolved solute to precipitate.

Temperature and Gas Solubility

Table 13.2 lists the solubilities of several common gases in water at different temperatures, but all under 1 atm of pressure. In water, gases such as oxygen are usually more soluble at colder temperatures. Dissolved oxygen in lakes, streams, and oceans is extracted through the gills of marine animals. Fish generally seek colder waters because of the higher concentration of oxygen. **Hypoxia,** a condition in which oxygen concentrations are critically low, has been known to cause massive fish kills.

The solubility of gases, like other solubilities, can increase or decrease with temperature, depending on the gas and the solvent. For example, the solubilities of H_2, N_2, CO, He, and Ne actually increase with rising temperature in common organic solvents like carbon tetrachloride, toluene, and acetone.

Table 13.2 Solubilities of Common Gases in Water[a]

	Temperature			
Gas	**0 °C**	**20 °C**	**50 °C**	**100 °C**
Nitrogen, N_2	0.0029	0.0019	0.0012	0
Oxygen, O_2	0.0069	0.0043	0.0027	0
Carbon dioxide, CO_2	0.335	0.169	0.076	0
Sulfur dioxide, SO_2	22.8	10.6	4.3	1.8[b]
Ammonia, NH_3	89.9	51.8	28.4	7.4[c]

[a] Solubilities are in grams of solute per 100 g of water when the gaseous space over the liquid is saturated with the gas and the total pressure is 1 atm.

[b] Solubility at 90 °C.

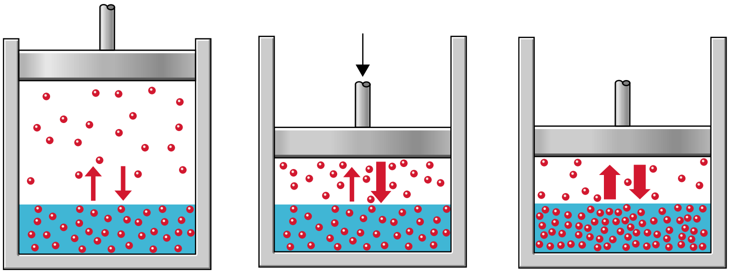
[c] Solubility at 96 °C.

13.4 | Henry's Law

The solubility of a gas in a liquid increases with increasing pressure. To understand this at the molecular level, imagine the following equilibrium established in a closed container fitted with a movable piston (Figure 13.11*a*).

$$\text{gas} + \text{solvent} \rightleftharpoons \text{solution} \tag{13.3}$$

If the piston is pushed down (Figure 13.11*b*), the gas is compressed and its pressure increases. This causes the concentration of the gas molecules over the solution to increase, so the rate at which the gas dissolves is now greater than the rate at which it leaves the solution. Eventually, equilibrium is reestablished when the concentration of the gas in the solution has increased enough to make the rate of escape equal to the rate at which the gas dissolves (Figure 13.11*c*). At this point, the concentration of the gas in the solution is higher than before.



(*a*) (*b*) (*c*)

Figure 13.11 | **How pressure increases the solubility of a gas in a liquid.** (*a*) At some specific pressure, equilibrium exists between the vapor phase and the solution. (*b*) An increase in pressure upsets the equilibrium. More gas molecules are dissolving than are leaving the solution. (*c*) More gas has dissolved and equilibrium is restored.

The effect of pressure on the solubility of a gas can also be explained by Le Châtelier's principle and Equation 13.3. In this case, the disturbance is an increase in the pressure of the gas above the solution. How could the system counteract the pressure increase? The answer is: by having more gas dissolve in the solution. In this way, the pressure of the gas is reduced and the concentration of the gas in the solution is increased. In other words, increasing the pressure of the gas will cause the gas to become more soluble.

Figure 13.12 shows how the solubility in water of oxygen and nitrogen vary with pressure. The straight lines on the graph indicate that the concentration of the gas is directly proportional to its pressure above the solution. This is expressed quantitatively by **Henry's law**, which states that *the concentration of a gas in a liquid at any given temperature is directly proportional to the partial pressure of the gas over the solution.*

- William Henry (1774–1836), an English chemist, first reported the relationship between gas solubility and pressure.

Henry's law

$$C_{\text{gas}} = k_{\text{H}} P_{\text{gas}} \qquad (T \text{ is constant}) \tag{13.4}$$

where C_{gas} is the concentration of the gas and P_{gas} is the partial pressure of the gas above the solution. The proportionality constant, k_{H}, called the Henry's law constant, is unique to each gas. The equation is an approximation that works best at low concentrations and pressures and for gases that do not react with the solvent.

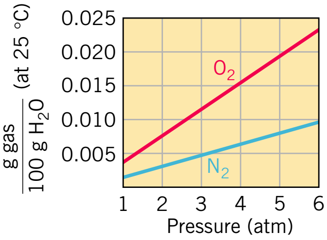


Figure 13.12 | **Solubility in water versus pressure for two gases**. The amount of gas that dissolves increases as the pressure is raised.

Bottled carbonated beverages fizz when the bottle is opened because the sudden drop in pressure causes a sudden drop in gas solubility. *(Andy Washnik)*

An alternate (and commonly used) form of Henry's law is

$$\frac{C_1}{P_1} = \frac{C_2}{P_2} \tag{13.5}$$

where the subscripts 1 and 2 refer to initial and final conditions, respectively. By taking the ratio, the Henry's law constant cancels.

Example 13.1
Solubility of Nitrogen Using Henry's Law

At 20.0 °C the solubility of N_2 in water is 0.0152 g L^{-1} when the partial pressure of nitrogen is 585 torr. What will be the solubility of N_2 in water at 20.0 °C when its partial pressure is 823 torr?

■ **Analysis:** This problem deals with the effect of gas pressure on gas solubility, so Henry's law applies.

■ **Assembling the Tools:** We use Henry's law in its form given by Equation 13.5 because it lets us avoid having to know or calculate the Henry's law constant.

■ **Solution:** Let's gather the data first, making sure to distinguish between the initial (C_1 and P_1) and final conditions (C_2 and P_2).

$$\begin{aligned} C_1 &= 0.0152 \text{ g L}^{-1} \qquad & C_2 &= \text{unknown} \\ P_1 &= 585 \text{ torr} & P_2 &= 823 \text{ torr} \end{aligned}$$

Using Equation 13.5, we have

$$\frac{0.0152 \text{ g L}^{-1}}{585 \text{ torr}} = \frac{C_2}{823 \text{ torr}}$$

After multiplying both sides by 823 torr we solve for C_2,

$$C_2 = 0.0214 \text{ g L}^{-1}$$

The solubility under the higher pressure is 0.0214 g L^{-1}.

■ **Is the Answer Reasonable?** In relationship to the initial concentration, the size of the answer makes sense because Henry's law tells us to expect a greater solubility at the higher pressure.

Practice Exercises

13.1 | At 25 °C and standard pressure, a hydrogen sulfide solution can be made by bubbling $H_2S(g)$ into water; the result is a 0.11 molar solution. Since $H_2S(g)$ is more dense than air we can assume that a layer of pure $H_2S(g)$ at atmospheric pressure covers the solution. What is the value of Henry's law constant, and is the solubility of $H_2S(g)$ much greater or smaller than other gases mentioned in this section? If so, suggest a reason for the difference. (*Hint:* What is the pressure of the $H_2S(g)$?)

13.2 | How many grams of nitrogen and oxygen are dissolved in 125 g of water at 20.0 °C when the water is saturated with air? At 1.00 atm pressure, the solubility of pure oxygen in water is 0.00430 g O_2/100.0 g H_2O, and the solubility of pure nitrogen in water is 0.00190 g N_2/100.0 g H_2O. In pure, dry air, P_{N_2} equals 593 torr and P_{O_2} equals 159 torr.

Solutions of Gases that React with Water

The gases sulfur dioxide, ammonia, and, to a lesser extent, carbon dioxide are far more soluble in water than are oxygen or nitrogen (see Table 13.2). Part of the reason is that SO_2, NH_3, and CO_2 molecules have polar bonds and sites of partial charge that attract water molecules, forming hydrogen bonds to help hold the gases in solution. Ammonia molecules, in addition, not only can accept hydrogen bonds from water (O—H···N) but also can donate them through their N—H bonds (N—H···O).

The more soluble gases, dissolved, also react with water to some extent as the following chemical equilibria show.

$$CO_2(aq) + H_2O \rightleftharpoons H_2CO_3(aq) \rightleftharpoons H^+(aq) + HCO_3^-(aq)$$
$$SO_2(aq) + H_2O \rightleftharpoons H^+(aq) + HSO_3^-(aq)$$
$$NH_3(aq) + H_2O \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

The forward reactions contribute to the higher concentrations of the gases in solution, as compared to gases such as O_2 and N_2 that do not react with water at all. Gaseous sulfur trioxide is very soluble in water because it reacts *quantitatively* (i.e., completely) with water to form sulfuric acid.[4]

$$SO_3(g) + H_2O \longrightarrow H^+ + HSO_4^-(aq)$$

13.5 | Temperature-Independent Concentration Units

In Section 5.6 you learned that for stoichiometry, *molar concentration* or *molarity,* mol/L, is a convenient unit of concentration because it lets us measure out moles of a solute simply by measuring volumes of solution. For studying physical and chemical properties, at different temperatures, molarity is not preferred because the molarity of a solution varies slightly with temperature. Most liquids expand slightly when heated, so a given solution will have a larger volume, and therefore a lower ratio of moles to volume, as its temperature is raised. When our measurements must be made at several different temperatures, temperature-independent concentration units are used. The most common of these are *percentage by mass*, *molality*, and *mole fraction* (or *mole percent*).

Percent Concentration

Concentrations of solutions are often expressed as a **percentage by mass** (sometimes called a *percent by weight*), which gives grams of solute per 100 grams of solution. Percentage by mass is indicated by % (w/w), where the "w" stands for "weight." To calculate a percentage by mass from solute and solution masses, we can use the **mass fraction** (the mass of solute divided by the mass of the solution) and multiply it by 100% as shown in the following formula:

$$\text{Percentage by mass} = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100\% \qquad \textbf{(13.6)}$$

TOOLS

Percentage by mass

---

[4] The "concentrated sulfuric acid" of commerce has a concentration of 93 to 98% H_2SO_4, or roughly 18 *M*. This solution takes up water avidly and very exothermically, removing moisture even out of humid air itself (and so must be kept in stoppered bottles). Because it is dense, oily, sticky, and highly corrosive, it must be handled with extreme care. Safety goggles and gloves must be worn when dispensing concentrated sulfuric acid. When making a more dilute solution, *always pour (slowly with stirring) the concentrated acid into the water.* If water is poured onto concentrated sulfuric acid, it can layer on the acid's surface, because the density of the acid is so much higher than water's (1.8 g mL^{-1} vs. 1.0 g mL^{-1} for water). At the interface, such intense heat can be generated that the steam thereby created could explode from the container, spattering acid around.

For example, a solution labeled "0.85% (w/w) NaCl" is one in which the ratio of solute to solution is 0.85 g of NaCl to 100.00 g of NaCl solution. This suggests that the percent concentration can be used as a conversion factor as illustrated in the following example. Also illustrated in this example is that often, the "(w/w)" symbol is omitted when writing mass percents.[5]

Percentages could also be called *parts per hundred*. Other similar expressions of concentration are *parts per million* (ppm) and *parts per billion* (ppb), where 1 ppm equals 1 g of component in 10^6 g of the mixture and 1 ppb equals 1 g of component in 10^9 g of the mixture. By analogy, we can see that ppm is simply the mass fraction multiplied by 10^6 ppm and ppb is the mass fraction multiplied by 10^9 ppb.

Example 13.2
Using Percent Concentrations

Seawater is typically 3.5% sea salt and has a density of 1.03 g mL^{-1}. How many grams of sea salt would be needed to prepare enough seawater solution to completely fill a 62.5 L aquarium?

Analysis: We need the number of grams of sea salt in 62.5 L of seawater solution. To solve the problem, we'll need a relationship that links seawater and sea salt. The percent concentration in Equation 13.6 is the link we need. We will assume that the percent is a percentage by mass.

Assembling the Tools: We can write "3.5% sea salt" as the following conversion equality:

$$3.5\ \text{g sea salt} \Leftrightarrow 100\ \text{g soln}$$

Density (see Section 2.5 page 51) provides the next conversion equality,

$$1.03\ \text{g soln} \Leftrightarrow 1.00\ \text{mL soln}$$

Finally, we will use the SI prefixes in Table 2.4, page 35 to convert mL to liters.

Solution: We will start by writing the question in equation form:

$$62.5\ \text{L soln} \Leftrightarrow ?\ \text{g sea salt}$$

The hard work has been done. We just need to assemble the information in a logical sequence and cancel the units.

$$62.5\ \cancel{\text{L soln}} \times \frac{1000\ \cancel{\text{mL soln}}}{1\ \cancel{\text{L soln}}} \times \frac{1.03\ \cancel{\text{g soln}}}{1\ \cancel{\text{mL soln}}} \times \frac{3.5\ \text{g sea salt}}{100\ \cancel{\text{g soln}}} = 2.3 \times 10^3\ \text{g sea salt}$$

Is the Answer Reasonable? If seawater is about 4% sea salt, 100 g of seawater should contain about 4 g of salt. A liter of seawater weighs about 1000 g, so it would contain about 40 g of salt. We have about 60 L of seawater, which would contain 60 × 40 g of salt, or 2400 g of salt. This is not too far from our answer, so the answer seems reasonable.

---

[5] Clinical laboratories sometimes report concentrations as **percent by mass/volume**, using the symbol "%(w/v)":

$$\text{percent by mass/volume} = \frac{\text{mass of solute (g)}}{\text{volume of solution (mL)}} \times 100\%$$

For example, a solution that is 4%(w/v) $SrCl_2$ contains 4 g of $SrCl_2$ dissolved in 100 mL of solution. Notice that with a percent by mass, we can use any units for the mass of the solute and mass of the solution, as long as they are the same for both. With percent by mass/volume, we *must* use grams for the mass of solute and milliliters for the volume of solution. If a percent concentration does not include a (w/v) or (w/w) designation, we assume that it is a percentage by mass.

Practice Exercises

13.3 | What volume of water at 20.0 °C ($d = 0.9982 \text{ g cm}^{-3}$) is needed to dissolve 45.0 g of sucrose to make a 10.0 %(w/w) solution? (*Hint:* You need the mass of water to solve this problem.)

13.4 | How many grams of NaBr are needed to prepare 25.0 g of 1.00%(w/w) NaBr solution in water? How many grams of water are needed? How many milliliters are needed, given that the density of water at room temperature is 0.988 g mL^{-1}?

13.5 | Muriatic acid is the commercial name for hydrochloric acid that can be purchased from hardware stores as a solution that is 37%(w/w) HCl. What mass of this solution contains 7.5 g of HCl?

Molal Concentration

The number of moles of solute per kilogram of *solvent* is called the **molal concentration** or the **molality** of a solution. The usual symbol for molality is ***m***.

$$\text{Molality} = m = \frac{\text{mol of solute}}{\text{kg of solvent}} \tag{13.7}$$

TOOLS

Molal concentration

For example, if we dissolve 0.500 mol of sugar in 1.00 kg of water, we have a 0.500 *m* solution of sugar. We would not need a volumetric flask to prepare the solution, because we weigh the solvent. Some important physical properties of a solution are related in a simple way to its molality, as we'll soon see.

It is important not to confuse *molarity* with *molality*.

$$\text{Molality} = m = \frac{\text{mol of solute}}{\text{kg of } \textit{solvent}} \qquad \text{Molarity} = M = \frac{\text{mol of solute}}{\text{L of } \textit{solution}}$$

■ Be sure to notice that molality is defined per kilogram of *solvent*, not kilogram of solution.

As we pointed out at the beginning of this section, the molarity of a solution changes slightly with temperature, but molality does not. Therefore, molality is more convenient in experiments involving temperature changes. As we saw with molarity, molality can be used as a conversion factor. For example, the sugar solution above gives us the following equivalence:

$$0.500 \text{ mol sugar} \Leftrightarrow 1.00 \text{ kg H}_2\text{O}$$

When water is the solvent, a solution's molarity approaches its molality as the solution becomes more dilute. In very dilute solutions, 1.00 L of *solution* is nearly 1.00 L of pure water, which has a mass close to 1.00 kg. Under these conditions, the ratio of moles/liter (molarity) is very nearly the same as the ratio of moles/kilogram (molality).

■ This only applies when the solvent is water. For other solvents, molarity and molality have quite different values for the same solution.

Example 13.3
Preparation of a Solution of a Given Molality

An experiment calls for a 0.150 *m* solution of sodium chloride in water. How many grams of NaCl would have to be dissolved in 500.0 g of water to prepare a solution of this molality?

■ **Analysis:** In this problem, we are given two numerical values: the molality and the mass of water. Since we just saw that the molality can be used as a conversion factor, we will use to determine the mass of NaCl we need to dissolve in 500.0 g of water.

■ **Assembling the Tools:** First, we can use the given molality to write

$$0.150 \text{ mol NaCl} \Leftrightarrow 1.00 \text{ kg H}_2\text{O}$$

Next we need to determine the molar mass of NaCl (22.99 + 35.45 = 58.44 g NaCl mol^{-1}) to write the conversion equality between moles and mass,

$$1 \text{ mol NaCl} = 58.44 \text{ g NaCl}$$

Solution: We now write the question in equation form as

$$500.0 \text{ g } H_2O = ? \text{ g NaCl}$$

and then we write the appropriate conversion factors as shown next.

$$500.0 \ \cancel{\text{g } H_2O} \times \frac{0.150 \ \cancel{\text{mol NaCl}}}{1.00 \times 10^3 \ \cancel{\text{g } H_2O}} \times \frac{58.44 \text{ g NaCl}}{1 \ \cancel{\text{mol NaCl}}} = 4.38 \text{ g NaCl}$$

When 4.38 g of NaCl is dissolved in 500.0 g of H_2O, the concentration is 0.150 *m* NaCl.

Is the Answer Reasonable? We'll round the formula mass of NaCl to 60, so 0.15 mol would weigh about 9 g. A 0.15 *m* solution would contain about 9 g NaCl in 1.00 kg of water. If we used only 500 g of water, we would need half as much salt, or about 4.5 g. Our answer is close to this, so it seems reasonable.

Practice Exercises

13.6 | If you prepare a solution by dissolving 44.00 g of sodium sulfate in 250.0 g of water, what is the molality of the solution? Is the molarity of this solution numerically larger or smaller than its molality? (*Hint:* Recall the definition of molality and molarity—see Sections 5.6 and 13.5 above.)

13.7 | Water freezes at a lower temperature when it contains solutes. To study the effect of methanol on the freezing point of water, we might begin by preparing a series of solutions of known molalities. Calculate the number of grams of methanol (CH_3OH) needed to prepare a series of solutions from 0.050 to 0.250 *m* in 0.050 *m* increments. For each solution use 200.0 g of water.

13.8 | What mass of a 0.853 molal solution of iron(III) nitrate is needed to obtain (a) 0.0200 moles of iron(III) nitrate, (b) 0.0500 moles of Fe^{3+} ions, (c) 0.00300 moles of nitrate ions?

Mole Fraction and Mole Percent

Mole fraction and mole percent are important tools that were discussed in Chapter 11 (page 502), so for the sake of completeness we will just review the definitions. The mole fraction, X_A, of a substance A is given by

$$X_A = \frac{n_A}{n_A + n_B + n_C + n_D + \cdots + n_Z} \tag{13.8}$$

where n_A, n_B, n_C, . . . , n_Z are the numbers of moles of each component, *A, B, C*, . . . , *Z* respectively. The sum of all mole fractions for a mixture must always equal 1. The **mole percent** is obtained by multiplying the mole fraction by 100 mol%.

$$\text{mol percent A} = \frac{n_A}{n_A + n_B + n_C + n_D + \cdots + n_Z} \times 100 \text{ mol\%} \tag{13.9}$$

The mole fractions of all components of a mixture add up to 1.00, so the mole percents must add up to 100 mol%.

Conversions among Concentration Units

There are times when we need to change from one concentration unit to another. The following example shows that, when converting from one temperature-independent concentration unit to another, all the information we need is in the definitions of the units. As you perform more complex conversions, it may be helpful to construct a table of data similar to the one below. Then you will have all the information needed at your fingertips.

Solvent	Solute	Solution
Mass	Mass	Total mass
Moles	Moles	Total moles
Volume	Volume	Total volume
Solvent molar mass	Solute molar mass	Density

Use a table such as this to keep track of solution data. Items in green are often found in tables if not given in a problem. Red items are replaced with known data. Perform conversions, as needed, to fill in remaining boxes.

Example 13.4
Finding Molality from Mass Percent

Brine is a fairly concentrated solution of sodium chloride in water. One use for brine is in the curing process for certain cheeses, where the concentration of brine affects the quality of the cheese. A supplier offers a cheese manufacturer a good price on 1.90 *m* brine. The cheesemaker needs a 10.0% (w/w) aqueous NaCl solution. Show whether or not the 1.90 *m* brine solution will be okay to use.

- **Analysis:** In this problem we have a choice of methods to compare 1.90 *m* and 10.0% (w/w) brine to see whether they are equivalent. We can convert molality to %(w/w) or %(w/w) to molality. Let's do the latter conversion of %(w/w) to molality. First, we write the conversion we are asked to perform in equation form.

$$\frac{10.0\ \text{g NaCl}}{100.0\ \text{g NaCl soln}} \quad \text{to} \quad \frac{?\ \text{mol NaCl}}{1.00\ \text{kg water}}$$

This will involve conversion of mass to moles for NaCl and g to kg for water.

- **Assembling the Tools:** The equality for converting mass to moles is

$$58.44\ \text{g NaCl} = 1.00\ \text{mol NaCl}$$

We need to convert 100.0 g of the NaCl solution to the mass of water. Since the mass of the solution is the mass of solute plus the mass of water, we write

$$100.0\ \text{g NaCl solution} = 10.0\ \text{g NaCl} + 90.0\ \text{g}\ H_2O$$

From this we can write the equivalence

$$100.0\ \text{g NaCl solution} \Leftrightarrow 90.0\ \text{g}\ H_2O$$

Then we will use the SI prefixes for the conversion of grams to kilograms.

- **Solution:** First, we write the question as an equation,

$$\frac{10.0\ \text{g NaCl}}{100.0\ \text{g NaCl soln}} = \frac{?\ \text{mol NaCl}}{1\ \text{kg water}}$$

We can see that the logical first step will be to convert the mass of NaCl to moles. Then in two conversions we convert the mass of solution to kg of water

$$\frac{10.0\ \text{g}\ \cancel{\text{NaCl}}}{100.0\ \text{g}\ \cancel{\text{NaCl soln}}} \times \frac{1\ \text{mol NaCl}}{58.44\ \text{g}\ \cancel{\text{NaCl}}} \times \frac{100.0\ \text{g}\ \cancel{\text{NaCl soln}}}{90.0\ \cancel{\text{g water}}} \times \frac{1000\ \cancel{\text{g water}}}{1\ \text{kg water}} = 1.90\ m\ \text{NaCl}$$

We conclude that 10.0% NaCl solution would also be 1.90 molal and the supplier's product is acceptable.

Is the Answer Reasonable? A convenient rounding of the numbers in our calculation to one significant figure might be

$$\frac{10\text{ }\cancel{\text{g NaCl}}}{100\text{ g }\cancel{\text{NaCl soln}}} \times \frac{1\text{ mol NaCl}}{50\text{ }\cancel{\text{g NaCl}}} \times \frac{100\text{ g }\cancel{\text{NaCl soln}}}{100\text{ }\cancel{\text{g water}}} \times \frac{1000\text{ }\cancel{\text{g water}}}{1\text{ kg water}} = 2\ m\text{ NaCl}$$

This is close to our calculated value, and we conclude we were correct. Notice that rounding the 58.6 down to 50 compensates for rounding 90 up to 100, so our estimate is closer to the correct number. We do not need a calculator for this estimate. First, cancel five zeros from the numerator numbers and five zeros from the denominator numbers. This leaves you with 10/5 = 2.

Practice Exercises

13.9 | A bottle on the stockroom shelf reads 52% sodium hydroxide solution. What is the molality of this solution? (*Hint:* Recall that the % means (w/w) percentage.)

13.10 | A certain sample of concentrated hydrochloric acid is 37.0% HCl. Calculate the molality of this solution.

13.6 | Temperature-Dependent Concentration Units

In Chapter 5 we were introduced to molarity as a concentration unit and to its usefulness as a conversion factor.

$$M = \frac{\text{moles of solute}}{\text{liters of solution}} \tag{13.10}$$

The molarity is also temperature dependent because the denominator will change with changes in temperature. Another temperature-dependent concentration unit is the mass–volume percentage, defined as

Volume/volume percentages (%v/v) are also sometimes used for liquid solutions. This is the number of mL of solute in 100 mL of solution.

$$\%(\text{w/v}) = \frac{\text{grams solute}}{\text{mL solution}} \times 100\% \tag{13.11}$$

Conversions between the two temperature-dependent units are done in two steps: first, the numerators can be converted between moles and mass, and second, the denominators are then a simple conversion between mL and L units.

When we want to convert between a temperature-dependent concentration unit such as molarity and a temperature-independent unit such as molality, we need to know the density of the solution. Example 13.5 illustrates this method.

Example 13.5
Finding Molarity from Mass Percent

A certain supply of concentrated hydrochloric acid has a concentration of 36.0% HCl. The density of the solution is 1.19 g mL^{-1}. Calculate the molar concentration of HCl.

Analysis: Recall the definitions of percentage by mass and molarity. We must perform the following conversion:

$$\frac{36.0\text{ g HCl}}{100\text{ g HCl soln}} \quad \text{to} \quad \frac{?\text{ mol HCl}}{1\text{ L HCl soln}}$$

We have two conversions to perform. In the numerator we need to convert the mass of HCl to moles HCl, and in the denominator we convert the mass of solution to liters of solution.

Assembling the Tools: We need the mass-to-moles equality for HCl. The molar mass of HCl is 36.46, and we write the equality as

$$1.000\text{ mol HCl} = 36.46\text{ g HCl}$$

We use the density to write the equality

$$1.19\text{ g solution} = 1.00\text{ mL solution}$$

Finally, we use the SI prefixes to obtain the correct volume units.

Solution: We first write the question in equation form,

$$\frac{36.0\text{ g HCl}}{100\text{ g HCl soln}} = ?\,\frac{\text{mol HCl}}{1\text{ L HCl soln}}$$

We can do the conversions in either order. Here, we'll convert the numerator first:

$$\frac{36.0\text{ g }\cancel{\text{HCl}}}{100\text{ g }\cancel{\text{HCl soln}}} \times \frac{1\text{ mol HCl}}{36.46\text{ g }\cancel{\text{HCl}}} \times \frac{1.19\text{ g }\cancel{\text{HCl soln}}}{1.00\ \cancel{\text{mL HCl soln}}} \times \frac{1000\ \cancel{\text{mL HCl soln}}}{1\text{ L HCl soln}} = 11.8\ M\text{ HCl}$$

So 36.0% HCl is also 11.8 M HCl.

Is the Answer Reasonable? We can estimate the answer in our head. First, cancel the 36 g HCl in the numerator and the 36.46 g HCl in the denominator to give ~1.0 (shown in red below). Now we divide 1000 in the numerator by 100 in the denominator to get 10 (shown in blue). All that is left is $1.19 \times 10 = 11.9\ M$ as shown below.

$$\frac{36.0}{100} \times \frac{1\text{ mol HCl}}{36.46} \times \frac{1.19}{1.00} \times \frac{1000}{1\text{ L HCl soln}} = 11.9\ M\text{ HCl}$$

This is very close to our calculated answer and we can be confident in our result.

Practice Exercises

13.11 | Hydrobromic acid can be purchased as 40.0% solution. The density of this solution is 1.38 g mL^{-1}. What is the molar concentration of hydrobromic acid in this solution?

13.12 | One gram of aluminum nitrate is dissolved in 1.00 liter of water at 20.0 °C. The density of water at this temperature is 0.9982 g cm^{-3} and the density of the resulting solution is 0.9989 g cm^{-3}. Calculate the molarity and molality of this solution.

Practice Exercise 13.12 illustrates that when the concentration of an aqueous solution is very low—one gram per liter, for example—the molality and the molarity are very close to the same numerical value. As a result, we can conveniently interchange molality and molarity when aqueous solutions are very dilute.

13.7 | Colligative Properties

The physical properties of solutions to be studied in this and succeeding sections are called **colligative properties**, because they depend mostly on the concentrations of particles in mixtures, not on their chemical identities. We start with an examination of the effects of solutes on the vapor pressures of solvents in liquid solutions.

■ After the Greek *kolligativ*, depending on number and not on nature.

Raoult's Law

■ Francois Marie Raoult (1830–1901) was a French scientist.

All liquid solutions of *nonvolatile* solutes (solutes that have no tendency to evaporate) have lower vapor pressures than their pure solvents. The vapor pressure of such a solution is proportional to how much of the solution actually consists of the solvent. This proportionality is given by **Raoult's law**, which says that the vapor pressure of the solution, P_{solution}, equals the mole fraction of the solvent, X_{solvent}, multiplied by its vapor pressure when pure, $P°_{\text{solvent}}$. In equation form, Raoult's law is expressed as follows.

TOOLS Raoult's law

Raoult's Law equation

$$P_{\text{solution}} = X_{\text{solvent}}\, P°_{\text{solvent}} \tag{13.12}$$

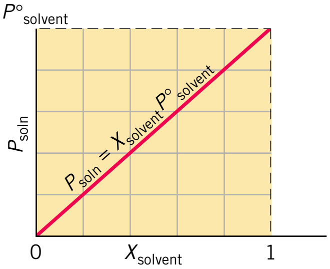

Figure 13.13 | **A Raoult's law plot.**

Because of the form of this equation, a plot of P_{solution} versus X_{solvent} should be *linear* at all concentrations when the system obeys Raoult's law (see Figure 13.13).

Notice that the mole fraction in Raoult's law refers to the solvent, not the solute. Usually we're more interested in the effect of the *solute's* mole fraction concentration, X_{solute}, on the vapor pressure. We can show that the change in vapor pressure, ΔP, is directly proportional to the mole fraction of solute, X_{solute}, as follows.[6]

$$\Delta P = X_{\text{solute}}\, P°_{\text{solvent}} \tag{13.13}$$

The change in vapor pressure equals the mole fraction of the solute times the solvent's vapor pressure when pure.

Example 13.6
Determining Vapor Pressures with Raoult's Law

Carbon tetrachloride has a vapor pressure of 155 torr at 20 °C. This solvent can dissolve candle wax, which is essentially nonvolatile. Although candle wax is a mixture, we can take its molecular formula to be $C_{22}H_{46}$ (molar mass = 311 g mol^{-1}). Without any change in temperature, by how much will the vapor pressure of CCl_4 be lowered when a solution is prepared by dissolving 10.0 g of wax in 40.0 g of CCl_4 (molar mass = 154 g mol^{-1})? What is the final vapor pressure of this solution?

■ **Analysis:** This question uses Raoult's law, which, in turn, uses mole fractions that are determined using our previously learned mole conversions. We have to work backward through this sequence to determine the change in vapor pressure of the solution. We then use that change to determine the actual vapor pressure.

---

[6] To derive Equation 13.13, note that the value of ΔP is simply the following difference.

$$\Delta P = (P°_{\text{solvent}} - P_{\text{solution}})$$

The mole fractions for our two-component system, X_{solvent} and X_{solute}, must add up to 1; it's the nature of mole fractions.

$$X_{\text{solvent}} = 1 - X_{\text{solute}}$$

We now insert this expression for X_{solvent} into the Raoult's law equation.

$$P_{\text{solution}} = X_{\text{solvent}} P°_{\text{solvent}}$$
$$P_{\text{solution}} = (1 - X_{\text{solute}}) P°_{\text{solvent}} = P°_{\text{solvent}} - X_{\text{solute}} P°_{\text{solvent}}$$

So, by rearranging terms,

$$X_{\text{solute}} P°_{\text{solvent}} = P°_{\text{solvent}} - P_{\text{solution}} = \Delta P$$

This result gives us Equation 13.13.

Assembling the Tools: We will use the version of Raoult's law as given in Equation 13.13. Since we know the vapor pressure of the pure solvent, we will have to use Equation 13.8 to determine the mole fraction of the solute to determine the change in vapor pressure.

$$X_{\text{solute}} = \frac{n_{\text{solute}}}{n_{\text{solvent}} + n_{\text{solute}}}$$

We are given the masses of the solvent and solute and can calculate the moles of each in order to use this equation. We use our mass-to-moles equalities to determine the moles of CCl_4 and $C_{22}H_{46}$.

$$1 \text{ mol } CCl_4 = 154 \text{ g } CCl_4 \qquad \text{and} \qquad 1 \text{ mol } C_{22}H_{46} = 311 \text{ g } C_{22}H_{46}$$

For the second part of the problem, we can use Raoult's law, Equation 13.12, or simply subtract the decrease in vapor pressure from the vapor pressure of pure carbon tetrachloride. The subtraction seems simpler, so we will use it.

Solution: Working backward in our analysis, we first have to determine the moles of each substance in the mixture. Our calculations are

$$\text{For } CCl_4 \qquad 40.0 \ \cancel{\text{g } CCl_4} \times \frac{1 \text{ mol } CCl_4}{154 \ \cancel{\text{g } CCl_4}} = 0.260 \text{ mol } CCl_4$$

$$\text{For } C_{22}H_{46} \qquad 10.0 \ \cancel{\text{g } C_{22}H_{46}} \times \frac{1 \text{ mol } C_{22}H_{46}}{311 \ \cancel{\text{g } C_{22}H_{46}}} = 0.0322 \text{ mol } C_{22}H_{46}$$

The total number of moles is 0.292 mol. Now we can calculate the mole fraction of the solute, $C_{22}H_{46}$,

$$X_{C_{22}H_{46}} = \frac{0.0322 \ \cancel{\text{mol}}}{0.292 \ \cancel{\text{mol}}} = 0.110$$

The amount that the vapor pressure is lowered, ΔP, will be this particular mole fraction, 0.110, times the vapor pressure of pure CCl_4 (155 torr at 20 °C), calculated by Equation 13.13.

$$\Delta P = 0.110 \times 155 \text{ torr} = 17.0 \text{ torr}$$

The presence of the wax in the CCl_4 lowers the vapor pressure of the CCl_4 by 17.0 torr. The actual vapor pressure will be 155 torr − 17 torr = 138 torr.

Is the Answer Reasonable? Our quickest check is that the vapor pressure is lowered and the amount it is lowered is approximately 10% of the original vapor pressure. Ten percent of 155 is close to our answer, 17.0 torr, and we are satisfied that it is reasonable. The last step to get the total vapor pressure is an easy subtraction.

Practice Exercises

13.13 | Dibutyl phthalate, $C_{16}H_{22}O_4$ (molar mass 278 g mol^{-1}), is an oil sometimes used to soften plastic articles. Its vapor pressure is negligible around room temperature. What is the vapor pressure, at 20.0 °C, of a solution of 20.0 g of dibutyl phthalate in 50.0 g of pentane, C_5H_{12} (molar mass 72.2 g mol^{-1})? The vapor pressure of pure pentane at 20.0 °C is 541 torr. (*Hint:* Calculate mole fractions first.)

13.14 | Acetone (molar mass = 58.0 g mol^{-1}) has a vapor pressure at a given temperature of 162 torr. At the same temperature, how many grams of nonvolatile stearic acid (molar mass = 284.5 g mol^{-1}) must be added to 156 g of acetone to decrease its vapor pressure to 155 torr?

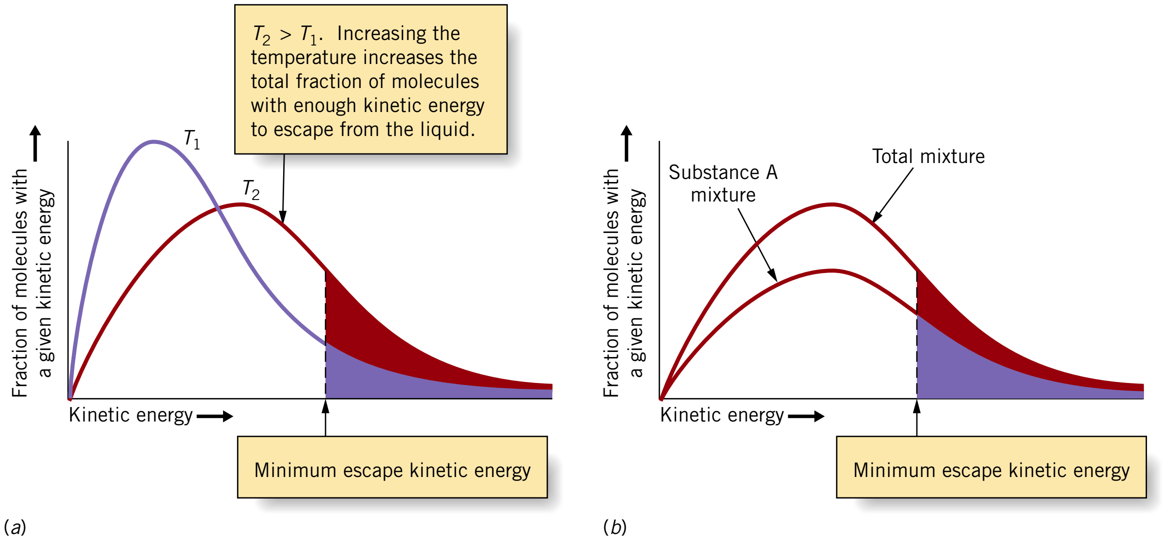

Figure 13.14 | **Kinetic energy distributions explain decreases in vapor pressure.** (*a*) Two KE distribution curves, one at a high temperature T_{high} and one at a low temperature T_{low}. The purple-shaded portion for the low temperature shows a decrease in the fraction of molecules able to escape the liquid phase compared to the purple and red areas combined for the high temperature curve. (*b*) A KE distribution curve for a mixture with a 0.333 mole fraction of nonvolatile solute mixed with the same volatile solvent as in (*a*). The purple-shaded area represents the fraction of volatile molecules able to leave the liquid phase. The purple and red areas combined represent the fraction of all molecules with that energy, but the molecules represented by the red area cannot vaporize until they achieve a much higher KE.

Raoult's Law and a Nonvolatile Solute

In Chapter 12 we saw that the vapor pressure of a volatile liquid changes with temperature. In particular, if we lower the temperature, the vapor pressure decreases. Figure 13.14*a* illustrates that the lowered vapor pressure was due to a smaller fraction of all molecules having enough energy to leave the liquid state. Figure 13.14*b* shows how a similar decrease in the fraction of energetic molecules results from the presence of a nonvolatile solute.

In Figure 13.14*b* the lower curve represents the KE distribution for the volatile part of the mixture, substance *A*, and the KE distribution for the nonvolatile substance, *B*, is added to it to obtain the upper curve that represents the KE distribution for the entire solution. We can see that the height of the lower curve is consistently 2/3 that of the upper curve. This is because we assumed a mole fraction of 0.667 for *A*. Also, the fraction of *all* molecules that exceed the kinetic energy needed by *A* to escape the solution has not changed. What has changed is that only 2/3 of those molecules are *A*—the rest are *B* and they can't escape the solution. The molecular view of this effect is shown in Figure 13.15.

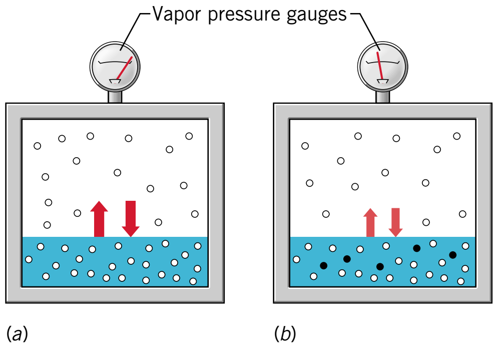

Figure 13.15 | **Molecular view of a nonvolatile solute reducing the vapor pressure of a solvent.** (*a*) Equilibrium between a pure solvent and its vapor. With a high number of solvent molecules in the liquid phase, the rate of evaporation and condensation is relatively high. (*b*) In the solution, some of the solvent molecules have been replaced with solute molecules. There are fewer solvent molecules available to evaporate from solution. The evaporation rate is lower. When equilibrium is established, there are fewer molecules in the vapor. The vapor pressure of the solution is less than that of the pure solvent.

Raoult's Law and Two Volatile Solutes

When two (or more) components of a liquid solution can evaporate, the vapor contains molecules of each. Each volatile substance contributes its own partial pressure to the total pressure. By Raoult's law, the partial pressure of a particular component is directly proportional to the component's mole fraction in the solution. By Dalton's law of partial pressures, the total vapor pressure will be the sum of all the partial pressures. To calculate these partial pressures, we use the Raoult's law equation for each component.

When component A is present in a mole fraction of X_A, its partial pressure (P_A) is this fraction of its vapor pressure when pure—namely, P_A°.

$$P_A = X_A P_A^\circ$$

By the same argument, the partial pressure of component B, is

$$P_B = X_B P_B^\circ$$

■ Remember, P_A and P_B here are the *partial* pressures as calculated by Raoult's law.

The total pressure of the solution of liquids A and B is then, by Dalton's law of partial pressures, the sum of P_A and P_B.

$$P_{\text{solution}} = X_A P_A^\circ + X_B P_B^\circ \tag{13.14}$$

TOOLS

Raoult's law for two volatile solvents

Notice that Equation 13.14 contains the Raoult's law equation as a special case. If one component—say, component B—is nonvolatile, it has no vapor pressure (P_B° is zero) so the $X_B P_B^\circ$ term drops out, leaving the Raoult's law equation, 13.13.

Example 13.7

Calculating the Vapor Pressure of a Solution of Two Volatile Liquids

Acetone is a solvent for both water and molecular liquids that do not dissolve in water, like benzene. At 22 °C, acetone has a vapor pressure of 164 torr. The vapor pressure of water at 22 °C is 18.5 torr. Assuming that the mixture obeys Raoult's law, what would be the vapor pressure of a solution of acetone and water with 50.0 mol% of each?

■ **Analysis and Tools:** To find P_{total} we need to calculate the individual partial pressures and then add them together. Our tool is Equation 13.14.

■ **Solution:** A concentration of 50.0 mol% corresponds to a mole fraction of 0.500, so

$$\begin{aligned} P_{\text{acetone}} &= 0.500 \times 164 \text{ torr} = 82.0 \text{ torr} \\ P_{\text{water}} &= 0.500 \times 18.5 \text{ torr} = \underline{9.25 \text{ torr}} \\ P_{\text{total}} &= 91.2 \text{ torr} \end{aligned}$$

■ **Is the Answer Reasonable?** The vapor pressure of the solution (91.2 torr) has to be much higher than that of pure water (18.5 torr) because of the volatile acetone, but much less than that of pure acetone (164 torr) because of the high mole fraction of water. The answer seems reasonable.

Practice Exercises

13.15 | At 20.0 °C, the vapor pressure of cyclohexane, a nonpolar hydrocarbon, is 66.9 torr and that of toluene, a hydrocarbon related to benzene, is 21.1 torr. What is the vapor pressure of a solution of the two at 20.0 °C when toluene is present at a mole fraction of 0.250? (*Hint:* Recall that all mole fractions of the components of a mixture must add up to 1.00.)

13.16 | Using the information from Practice Exercise 13.15, calculate the expected vapor pressure of a mixture of cyclohexane and toluene that consists of 122 grams of each liquid.

Only ideal solutions obey Raoult's law exactly. The vapor pressures of real solutions are sometimes higher or sometimes lower than Raoult's law would predict. These differences between ideal and real solution behavior are quite useful. They can tell us whether the attractive forces in the pure solvents, before mixing, are stronger or weaker than the attractive forces in the mixture. Comparing experimental vapor pressures with the predictions of Raoult's law provide a simple way to compare the relative strengths of attractions between molecules in solution. When the attractions between unlike molecules in the mixture are stronger than those in the pure solvents, the experimental vapor pressure will be lower than calculated with Raoult's law. Conversely, when the attractions between unlike molecules in the mixture are weaker than those in the pure solvents, the experimental vapor pressure will be larger than Raoult's law predicts.

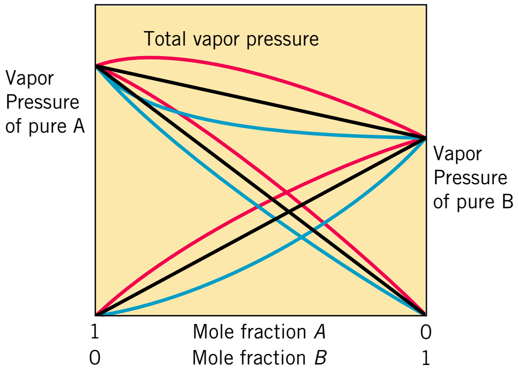

Figure 13.16 | **Vapor pressure vesus mole fraction of ideal and nonideal solutions.** Solutions are made with two volatile solvents. (*a*) The black lines represent an ideal solution, where the attractive forces in the mixture and pure liquids are the same and $\Delta H_{\text{soln}} = 0$. (*b*) Blue lines represent solutions that have an exothermic ΔH_{soln} and have stronger attractions in the mixture. (*c*) Red lines represent solutions that have an endothermic ΔH_{soln} and have weaker attractions in the mixture.

Referring back to Figure 13.7, we can see that when attractions between the unlike molecules in the mixture are stronger than those in the pure solvents, we should expect Step 3, the mixing process, to be more exothermic than Steps 1 and 2 combined. Therefore, a lower vapor pressure than expected indicates an exothermic heat of mixing that should be easily observed as a warming of the mixture. Similarly, if the vapor pressure of the mixture is greater than expected by Raoult's law, the heat of mixing will be endothermic. Figure 13.16 illustrates the shapes of the vapor pressure versus mole fraction curves for ideal solutions and two types of nonideal solutions.

Freezing Point Depression and Boiling Point Elevation

The lowering of the vapor pressure produced by the presence of a nonvolatile solute affects both the boiling and freezing points of a solution. This is illustrated for water in Figure 13.17. In this phase diagram, the solid blue lines correspond to the three equilibrium lines in the phase diagram for pure water, which we discussed in Section 12.10. Adding a nonvolatile solute lowers the vapor pressure of the solution, giving a new liquid–vapor equilibrium line for the solution, which is shown as the red line connecting points *A* and *B*.

When the solution freezes, the solid that forms is pure ice; there is no solute within the ice crystals. This is because the highly ordered structure of the solid doesn't allow solute molecules to take the place of water molecules. As a result, both pure water and the solution have the same solid–vapor equilibrium line on the phase diagram. Point *A* on the diagram is at the intersection of the liquid–vapor and solid–vapor equilibrium lines for the

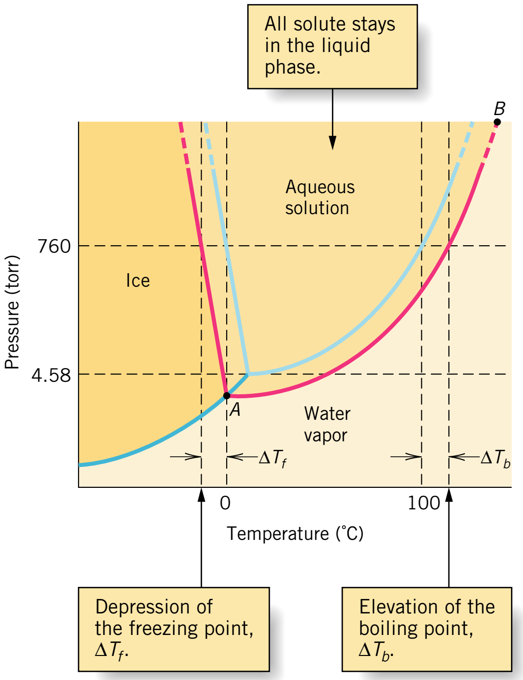

Figure 13.17 | **Phase diagrams for water and an aqueous solution.** Phase diagram for pure water (blue lines) and an aqueous solution of a nonvolatile solute (red lines).

solution and represents the new triple point for the solution. Rising from this triple point is the solid–liquid equilibrium line for the solution, shown in red.

If we look at where the solid–liquid and liquid–vapor lines cross the 1 atm (760 torr) pressure line, we can find the normal freezing and boiling points. For water (the blue lines), the freezing point is 0 °C and the boiling point is 100 °C. Notice that the solid–liquid line for the solution meets the 760 torr line at temperatures *below* 0 °C. In other words, the freezing point of the solution is below that of pure water. The amount by which the freezing point is lowered is called the **freezing point depression** and is given the symbol ΔT_f. Similarly, we can see that the liquid–vapor line for the solution crosses the 760 torr line at a temperature *above* 100 °C, so the solution boils at a higher temperature than pure water. The amount by which the boiling point is raised is called the **boiling point elevation.** It is given the symbol ΔT_b.

■ Recall that the definition of the normal boiling and freezing points specifies that the pressure is 1 atm.

Freezing point depression and boiling point elevation are both colligative properties. The magnitudes of ΔT_f and ΔT_b are proportional to the concentration of solute and solvent molecules. Molality (m) is the preferred concentration expression (rather than mole fraction or percent by mass) because of the resulting simplicity of the equations relating ΔT to concentration. The following equations work reasonably well only for dilute solutions, however.

$$\Delta T_f = K_f m \qquad (13.15)$$

$$\Delta T_b = K_b m \qquad (13.16)$$

TOOLS

Freezing point depression; boiling point elevation

K_f and K_b are proportionality constants and are called, respectively, the **molal freezing point depression constant** and the **molal boiling point elevation constant.** The values of both K_f and K_b are characteristic of each solvent (see Table 13.3). The units of each constant are °C m^{-1}. Thus, the value of K_f for a given solvent corresponds to the number of degrees of freezing point lowering for each molal unit of concentration. The K_f for water is 1.86 °C m^{-1}. A 1.00 m solution in water freezes at 1.86 °C *below* the normal freezing point of 0.00 °C, or at −1.86 °C. A 2.00 m solution should freeze at −3.72 °C. (We say "should" because systems are seldom this ideal.) Similarly, because K_b for water is 0.51 °C m^{-1}, a 1.00 m aqueous solution at 1 atm pressure boils at (100.00 + 0.51) °C or 100.51 °C, and a 2.00 m solution should boil at 101.02 °C.

Table 13.3 Molal Boiling Point Elevation and Freezing Point Depression Constants

Solvent	BP (°C)	K_b (°C m^{-1})	MP (°C)	K_f (°C m^{-1})
Water	100	0.51	0	1.86
Acetic acid	118.3	3.07	16.6	3.90
Benzene	80.2	2.53	5.45	5.07
Chloroform	61.2	3.63	−63.5	4.68
Camphor	—	—	178.4	39.7
Cyclohexane	80.7	2.69	6.5	20.2

Example 13.8
Estimating a Freezing Point Using a Colligative Property

Estimate the freezing point, at 1.0 atm, of a solution made from 10.0 g of urea, $CO(NH_2)_2$ (molar mass 60.06 g mol^{-1}), and 125 g of water.

■ **Analysis:** We need to use the appropriate equation for the freezing point depression. To use that equation we need to use the appropriate calculations to determine the molality of the solution.

Assembling the Tools: The main tool we need is expressed in Equation 13.15, the freezing point depression. We can look up the value for K_f and write the expression as

$$\Delta T_f = (1.86\ ^\circ\text{C}\ m^{-1})\ m$$

The equation for molality is

$$m = \frac{\text{mol urea}}{\text{kg water}}$$

and we use the molar mass of urea to convert the mass to the moles we need.

Solution: We write the equation that needs to be solved.

$$\Delta T_f = (1.86\ ^\circ\text{C molal}^{-1})\ m$$

Now to start the process for determining the molality, we'll convert grams of urea to moles.

$$10.0\ \cancel{\text{g CO(NH}_2\text{)}_2} \times \frac{1\ \text{mol CO(NH}_2\text{)}_2}{60.06\ \cancel{\text{g CO(NH}_2\text{)}_2}} = 0.166\ \text{mol CO(NH}_2\text{)}_2$$

and the 125 g to 0.125 kg of water. The molality is calculated as

$$\text{molality} = \frac{0.166\ \text{mol}}{0.125\ \text{kg}} = 1.33\ m$$

Now we solve the freezing point depression problem using the molality we just determined.

$$\begin{aligned}\Delta T_f &= (1.86\ ^\circ\text{C}\ \cancel{m^{-1}})(1.33\ \cancel{m}) \\ &= 2.47\ ^\circ\text{C}\end{aligned}$$

The solution should freeze at 2.47 °C below 0 °C, or at −2.47 °C.

Is the Answer Reasonable? For every unit of molality, the freezing point must be depressed by about 2 °C. The molality of this solution is between 1 m and 2 m, so we expect the freezing point depression to be between about 2 °C and 4 °C.

Practice Exercises

13.17 | In making candy, a certain recipe calls for heating an aqueous sucrose solution to the "soft-ball" stage, which has a boiling point of 235–240 °F. What is the range of mass percentages of the solutions of sugar ($C_{12}H_{22}O_{11}$) that boil at those two temperatures? (*Hint:* Remember that temperature changes are in °C.)

13.18 | How many grams of glucose (molar mass = 180.9 g mol^{-1}) must be dissolved in 255 g of water to raise the boiling point to 102.36 °C?

Determining Molar Masses

We have described freezing point depression and boiling point elevation as *colligative* properties; they depend on the relative *numbers* of particles, not on their kinds. Because the effects are proportional to molal concentrations, experimentally measured values of ΔT_f or ΔT_b can be useful for calculating the molar masses of unknown solutes. To do this, let's examine the molality part of the temperature change in Equations 13.15 and 13.16 more closely. If we expand the molality equation we get

$$m = \frac{\text{mol solute}}{\text{kg solvent}} = \frac{\left(\dfrac{\text{g solute}}{\text{molar mass solute}}\right)}{\text{kg solvent}}$$

This indicates that if we measure ΔT_f or ΔT_b and know the mass of solute in each kg of solvent, we can estimate the last remaining unknown, the molar mass. Example 13.9 shows how to estimate molar mass.

Example 13.9
Calculating a Molar Mass from Freezing Point Depression Data

A solution made by dissolving 5.65 g of an unknown molecular compound in 110.0 g of benzene froze at 4.39 °C. What is the molar mass of the solute?

■ **Analysis:** To calculate the molar mass (i.e., g mol^{-1}), we need to know two things about the same sample: the number of moles and the number of grams. In this example, we've been given the number of grams, and we have to use the remaining data to calculate the number of moles. We will need to expand the molarity part of the freezing point depression equation to do this, as suggested previously.

■ **Assembling the Tools:** Our basic tool is the freezing point depression equation 13.15.

$$\Delta T_f = K_f m$$

We will also use the definition of molality

$$m = \frac{\text{mol solute}}{\text{kg solvent}} \quad \text{and} \quad \text{mol solute} = \frac{\text{g solute}}{\text{molar mass solute}}$$

along with the expanded form for ΔT_f,

$$\Delta T_f = T_{f\ \text{pure}} - T_{f\ \text{observed}}$$

■ **Solution:** Table 13.3 tells us that the melting point of pure benzene is 5.45 °C and that the value of K_f for benzene is 5.07 °C m^{-1}. The amount of freezing point depression is

$$\Delta T_f = 5.45\ ^\circ\text{C} - 4.39\ ^\circ\text{C} = 1.06\ ^\circ\text{C}$$

We now use Equation 13.15 to find the molality of the solution,

$$\Delta T_f = K_f m$$

$$\text{molality} = \frac{\Delta T_f}{K_f} = \frac{1.06\ ^\circ\text{C}}{5.07\ ^\circ\text{C}\ m^{-1}} = 0.209\ m$$

This means that for every kilogram of benzene in the solution, there are 0.209 mol of solute. However, we have only 110.0 g or 0.1100 kg of benzene, so the actual number of moles of solute in the given solution is

$$0.1100\ \text{kg benzene} \times \frac{0.209\ \text{mol solute}}{1\ \text{kg benzene}} = 0.0230\ \text{mol solute}$$

We can now obtain the molar mass. There are 5.65 g of solute and 0.0230 mol of solute. Using the expression for calculating moles of solute we can write

$$0.0230\ \text{mol solute} = \frac{5.65\ \text{g solute}}{\text{molar mass solute}}$$

With a simple rearrangement,

$$\text{molar mass solute} = \frac{5.65\ \text{g solute}}{0.0230\ \text{mol solute}} = 246\ \text{g mol}^{-1}$$

The mass of one mole of the solute is 246 g.

Is the Answer Reasonable? A common mistake to avoid is using the given value of the freezing point, 4.39 °C, in Equation 13.15, instead of calculating ΔT_f. A check shows that we *have* calculated ΔT_f correctly. The ratio of ΔT_f to K_f is about 1/5, or 0.2 *m*, which corresponds to a ratio of 0.2 mol solute per 1 kg of benzene. The solution prepared has only 0.1 kg of solvent, so to have the same ratio, the amount of solute must be about 0.02 mol (2×10^{-2} mol). The sample weighs about 5 g, and dividing 5 g by 2×10^{-2} mol gives 2.5×10^2 g/mol, or 250 g/mol. This is very close to the answer we obtained, so we can feel confident it's correct.

Practice Exercises

13.19 | A solution made by dissolving 3.46 g of an unknown compound in 85.0 g of benzene froze at 4.13 °C. What is the molar mass of the compound? (*Hint:* Recall the equation for calculating moles of a substance to find the key relationship.)

13.20 | A mixture is prepared that is 5.0 %(w/w) of an unknown substance mixed with naphthalene (molar mass = 128.2 g mol^{-1}). The freezing point of this mixture is found to be 77.3 °C. What is the molar mass of the unknown substance? (The melting point of naphthalene is 80.2 °C and $K_f = 6.9$ °C m^{-1}.)

Osmosis

In living things, membranes of various kinds keep mixtures and solutions organized and separated. Yet some substances have to be able to pass through membranes so that nutrients and products of chemical work can be distributed correctly. These membranes, in other words, must have a selective *permeability*. They must keep some substances from going through while letting others pass. Such membranes are said to be *semipermeable.*

The degree of permeability varies with the kind of membrane. Cellophane, for example, is permeable to water and small solute particles—ions or molecules—but impermeable to very large molecules, like those of starch or proteins. Special membranes can even be prepared that are permeable only to water, not to any solutes.

Depending on the kind of membrane separating solutions of different concentrations, two similar phenomena, *dialysis* and *osmosis*, can be observed. Both are functions of the relative concentrations of the particles of the dissolved materials on each side of the membrane. Therefore, physical properties of these systems are also classified as colligative properties.

When a membrane is able to let both water and *small* solute particles through, such as the membranes in living systems, the process is called **dialysis**, and the membrane is called a **dialyzing membrane**. It does not permit huge molecules through, like those of proteins and starch. Artificial kidney machines use dialyzing membranes to help remove the smaller molecules of wastes from the blood while letting the blood retain its large protein molecules.

When a semipermeable membrane will let only solvent molecules get through, this movement is called *osmosis*, and the special membrane needed to observe it is called an **osmotic membrane**.

When **osmosis** occurs, there's a net shift of solvent across the membrane from the more dilute solution (or pure solvent) into the more concentrated solution. This happens because there is a tendency toward the equalization of concentrations between the two solutions in contact with one another across the membrane. The rate of passage of solvent molecules through the membrane into the more concentrated solution is greater than their rate of passage in the opposite direction, presumably because at the surface of the membrane the solvent concentration is greater in the more dilute solution (Figure 13.18*a*). This leads to a gradual net flow of water through the membrane into the more concentrated solution.

We observe an effect similar to osmosis if two solutions with unequal concentrations of a nonvolatile solute are placed in a sealed container (Figure 13.18*b*). The rate of evaporation

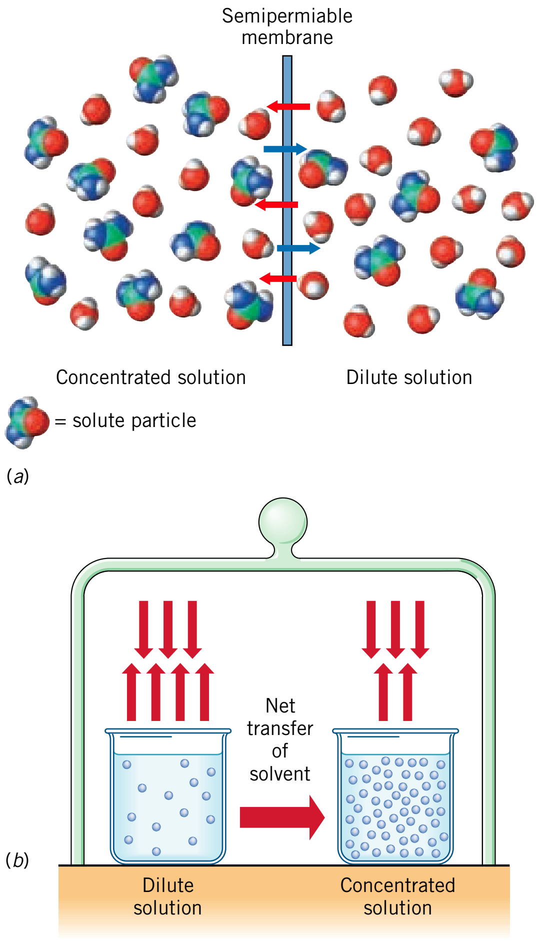

Figure 13.18 | **Principles at work in osmosis.** (*a*) Osmosis. Solvent molecules pass more frequently from the more dilute solution into the more concentrated one, as indicated by the arrows. This leads to a gradual transfer of solvent from the less concentrated solution into the more concentrated one. (*b*) Because the two solutions have unequal rates of evaporation, but the same rate of condensation, there is a gradual net transfer of solvent from the more dilute solution into the more concentrated one.

from the more dilute solution is greater than that of the more concentrated solution, but the rate of return to each is the same because both solutions are in contact with the same gas phase. As a result, neither solution is in equilibrium with the vapor. In the dilute solution, molecules of solvent are evaporating faster than they're condensing. In the concentrated solution, however, just the opposite occurs; more water molecules return to the solution than leave it. Therefore, over time there is a gradual net transfer of solvent from the dilute solution into the more concentrated one until they both achieve the same concentration and vapor pressure.

Osmotic Pressure

An osmosis experiment is illustrated in Figure 13.19. Initially, we have a solution (*B*) in a tube fitted with an osmotic membrane that dips into a container of pure water (*A*). As time passes, the volume of liquid in the tube increases as solvent molecules transfer into the solution. In Figure 13.19*b*, the net transport of water into the solution has visibly increased the volume.

The weight of the rising fluid column in Figure 13.19*b* provides a push or opposing pressure that makes it increasingly more difficult for molecules of water to enter the solution inside the tube. Eventually, this pressure becomes sufficient to stop the osmosis. The exact opposing pressure needed to prevent any osmotic flow *when one of the liquids is pure solvent* is called the **osmotic pressure** of the solution. If we apply further pressure, as illustrated in Figure 13.19*c*, we can force enough water back through the membrane to restore the system to its original condition.

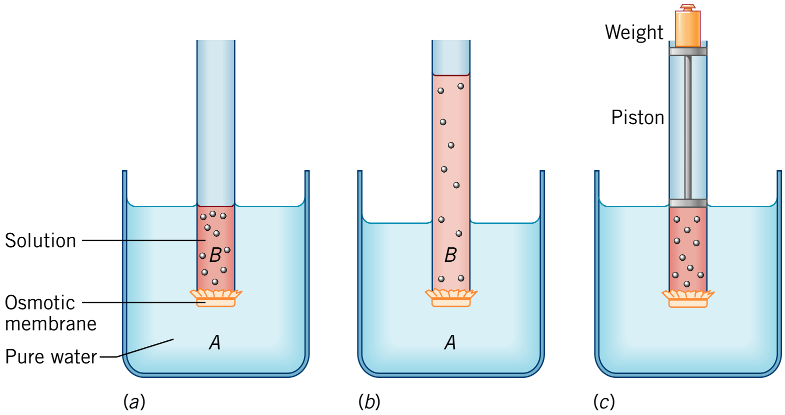

Figure 13.19 | **Osmosis and osmotic pressure.** (*a*) Initial conditions. A solution, *B*, is separated from pure water, *A*, by an osmotic membrane; no osmosis has yet occurred. (*b*) After a while, the volume of fluid in the tube has increased visibly. Osmosis has taken place. (*c*) A back pressure is needed to prevent osmosis. The amount of back pressure is called the osmotic pressure of the solution.

■ Reverse osmosis systems are available for home use at hardware stores. They can be installed to remove impurities and foul tastes from drinking water. Some bottled water available on supermarket shelves contains water that's been purified by reverse osmosis.

Notice that the term "osmotic pressure" uses the word *pressure* in a novel way. Apart from osmosis, a solution does not "have" a special pressure called osmotic pressure. What the solution has is a *concentration* that can generate the occurrence of osmosis and the associated osmotic pressure under the right circumstances. Then, in proportion to the solution's concentration, a specific back pressure is required to prevent osmosis. By *exceeding* this back pressure, osmosis can be reversed. **Reverse osmosis** is widely used to purify seawater, both on ocean-going ships and in arid locations where fresh water is scarce, polluted, or unavailable. (See more details in Chemistry and Current Affairs.)

The symbol for osmotic pressure is the Greek capital pi, Π. In a dilute aqueous solution, Π is proportional both to temperature, T, and molar concentration of the solute in the solution, M:

$$\Pi \propto MT$$

The proportionality constant turns out to be the gas constant, R, so for a *dilute* aqueous solution we can write

$$\Pi = MRT \tag{13.17}$$

TOOLS
Osmotic pressure

Of course, M is the ratio mol/L, which we can write as n/V, where n is the number of moles and V is the volume in liters. If we replace M with n/V in Equation 13.17 and rearrange terms, we have an equation for osmotic pressure identical in form to the ideal gas law.

$$\Pi V = nRT \tag{13.18}$$

Equation 13.18 is the *van't Hoff equation for osmotic pressure.*

Osmotic pressure is of tremendous importance in biology and medicine. Cells are surrounded with membranes that restrict the flow of salts but allow water to pass through freely. To maintain a constant amount of water, the osmotic pressure of solutions on either side of the cell membrane must be identical. For an example, a solution that is 0.85% NaCl by mass has the same osmotic pressure as the contents of red blood cells, and red blood cells bathed in this solution can maintain their normal water content. The solution is said to be *isotonic* with red blood cells. Blood plasma is an isotonic solution.

If the cell is placed in a solution with a salt concentration higher than the concentration within the cell, osmosis causes water to flow out of the cell. Such a solution is said to be *hypertonic*. The cell shrinks and dehydrates, and eventually dies. This process kills freshwater fish and plants that are washed out to sea.

CHEMISTRY AND CURRENT AFFAIRS 13.1

Pure Water by Reverse Osmosis

Many important issues face the world today, but none is more important than the availability of potable (pure and drinkable) water. As Table 1 shows, almost 97% of all water is saltwater found in the oceans and seas. Most of the freshwater is tied up in polar and glacier ice.

Table 1 Water Resources

Water Source	Amount in the World	Amount per Person
All water	1.4×10^9 km^3	0.2 km^3
Freshwater total	3.9×10^7 km^3	5.6×10^6 m^3
Freshwater, icebound	3.3×10^7 km^3	4.8×10^6 m^3
Freshwater, liquid	6.0×10^6 km^3	8.6×10^5 m^3

The average person in a developed country uses approximately 54 m^3 of water per year. While it seems that there may be plenty of water—the problem is availability. Temperate climates get plenty of rain and usually have adequate water in lakes, streams, and aquifers. However, temperate climates often have high population densities, resulting in high water usage along with a greater possibility of water pollution. In arid regions, water is scarce even though the populations may be small. In all cases, natural water is a valuable resource that may have to be augmented using available technology.

There are many technologies that can be used to obtain freshwater. Boiling and condensing water uses too much energy to be practical. However, very large scale, multi-stage vacuum distillation produces about 85% of the desalinized water in the world but requires significant energy input. Reverse osmosis uses less energy and can be designed for smaller applications. Other methods such as ion-exchange, electrodialysis, freezing, and solar dehumidification are also used.

Osmosis, as described in this chapter, involves spontaneous movement of pure solvent (usually water) through a membrane into a solution containing a solute. The tendency of the solvent to move through the membrane is measured as the osmotic pressure. To reverse the flow of water through an osmotic membrane, a pressure that exceeds the osmotic pressure needs to be applied to the solution side of the membrane. The result will be pure water extracted from a solution such as seawater. Figure 1 shows a schematic diagram of a reverse osmosis process. Figure 2 is a photo of a bank of reverse osmosis separation tubes in operation.

(*a*) (*b*) (*c*)

Figure 13.20 | **Effects of isotonic, hypertonic, and hypotonic solutions on red blood cells.** (*a*) In an isotonic solution (0.85% NaCl by mass), solutions on either side of the membrane have the same osmotic pressure, and there is no flow of water across the cell membrane. (*b*) In this hypertonic solution (5.0% NaCl by mass), water flows from areas of lower salt concentration (inside the cell) to areas of higher concentration (the hypertonic solution), causing the cell to dehydrate. (*c*) In this hypotonic solution (0.1% NaCl by mass), water flows from areas of lower salt concentration (the hypotonic solution) to areas of higher concentration (inside the cell). The cell swells and bursts. *(a: Dennis KunkelMicroscopy, Inc./VisualsUnlimited; b, c: Dr. Dennis Kunkel /VisualsUnlimited)*

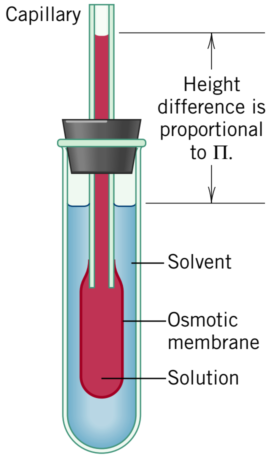

Figure 13.21 | **Simple osmometer.** When solvent moves into the solution by osmosis, the level of the solution in the capillary rises. The height reached can be related to the osmotic pressure of the solution.

On the other hand, water will flow into the cell if it is placed into a solution with an osmotic pressure that is much lower than the osmotic pressure of the cell's contents. Such a solution is called a *hypotonic* solution. A cell placed in distilled water, for example, will swell and burst. If you've ever tried to put in a pair of contact lenses with tap water instead of an isotonic saline solution, you've experienced cell damage from a hypotonic solution. The effects of isotonic, hypotonic, and hypertonic solutions on cells are shown in Figure 13.20.

Obviously, the measurement of osmotic pressure can be very important in preparing solutions that will be used to culture tissues or to administer medicines intravenously. Osmotic pressures can be measured by an instrument called an *osmometer*, illustrated and explained in Figure 13.21. Osmotic pressures can be very high, even in dilute solutions, as Example 13.10 shows.

Example 13.10
Calculating Osmotic Pressure

A very dilute solution, 0.00100 *M* sucrose in water, is separated from pure water by an osmotic membrane. What osmotic pressure in torr develops at 25 °C or 298 K?

■ **Analysis:** This question involves the application of the appropriate form of the osmotic pressure equation. Of course, we must be sure to use the correct value of *R*, so that the units work out correctly.

■ **Assembling the Tools:** We need to use Equation 13.17,

$$\Pi = MRT$$

Since we are given the temperature in kelvins and molarity has units of moles and liters, it is appropriate to choose $R = 0.0821 \text{ L atm mol}^{-1} \text{ K}^{-1}$.

■ **Solution:** Substituting into Equation 13.17, being sure to use the temperature in kelvins so the units cancel correctly,

$$\begin{aligned}\Pi &= (0.00100\ \cancel{\text{mol}}\ \cancel{\text{L}^{-1}})(0.0821\ \cancel{\text{L}}\ \text{atm}\ \cancel{\text{mol}^{-1}}\ \cancel{\text{K}^{-1}})(298\ \cancel{\text{K}})\\ &= 0.0245 \text{ atm}\end{aligned}$$

In torr we have

$$\Pi = 0.0245\ \cancel{\text{atm}} \times \frac{760\ \text{torr}}{1\ \cancel{\text{atm}}} = 18.6\ \text{torr}$$

The osmotic pressure of 0.00100 M sugar in water is 18.6 torr.

■ **Is the Answer Reasonable?** A 1 M solution should have an osmotic pressure of RT. Rounding the gas law constant to 0.08 and the temperature to 300, the osmotic pressure of a 1 M solution should be about 24 atm. The osmotic pressure of an 0.001 M solution should be 1/1000 of this, or about 0.024 atm, which is very close to what we got before we converted to torr.

Practice Exercises

13.21 | What is the osmotic pressure, in mm Hg and mm H_2O, of a protein solution when 5.00 g of the protein (molar mass = 235,000 g mol^{-1}) is used to prepare 100.0 mL of an aqueous solution at 4 °C? (*Hint:* The units needed for this calculation are specified by the value of R that is used.)

13.22 | What is the osmotic pressure in torr of a 0.0115 M glucose solution at body temperature (37 °C)? What are the boiling and freezing points for the same solution?

In the preceding example, you saw that a 0.0010 M solution of sugar has an osmotic pressure of 18.6 torr, which is equivalent to 18.6 mm Hg. This pressure is sufficient to support a column of the solution (which is mostly water) roughly 25 cm or 10 in high. If the solution had been 100 times as concentrated, 0.100 M sugar—(about the same as 1/4 of a teaspoon of sugar in your tea)—the height of the column supported would be roughly 25 m or over 80 ft! Osmotic pressure is one of several mechanisms by which water can reach the top of very tall trees.

Determining Molar Mass

An osmotic pressure measurement taken of a dilute solution can be used to determine the molar concentration of the solute, regardless of its chemical composition. Knowledge of the molarity, along with the mass of the solute in the solution, permits us to calculate the molar mass.

Determination of molar mass by osmotic pressure is much more sensitive than determination by the freezing point depression or boiling point elevation methods. The following example illustrates how osmotic pressure experiments can be used to determine molar mass.

Example 13.11
Determining Molar Mass from Osmotic Pressure

An aqueous solution with a volume of 100.0 mL and containing 0.122 g of an unknown molecular compound has an osmotic pressure of 16.0 torr at 20.0 °C. What is the molar mass of the solute?

■ **Analysis:** As we noted in Example 13.9, to determine a molar mass we need to measure two quantities for the same sample: its mass and the number of moles. Then, the molar mass is the ratio of grams to moles. We're given the number of *grams* of the solute, so we need to find the number of *moles* equivalent to this mass in order to compute the ratio.

■ **Assembling the Tools:** We can use the osmotic pressure Equation 13.18,

$$\Pi V = nRT$$

to calculate the number of moles, n. We need to convert the given pressure to 0.0211 atm. The temperature, 20.0 °C, corresponds to 293 K (273 + 20.0) and the volume of 100.0 mL corresponds to 0.1000 L. Since we are given the mass, we just need the definition of molar mass as the tool to complete the calculation.

■ $16.0\ \text{torr} \times \dfrac{1\ \text{atm}}{760\ \text{torr}} = 0.0211\ \text{atm}$

Solution: First, the number of moles, n, is calculated using the Equation 13.18 (with the data we just converted to the correct units),

$$(0.0211\ \cancel{\text{atm}})(0.1000\ \cancel{\text{L}}) = (n)(0.0821\ \cancel{\text{L}}\ \cancel{\text{atm}}\ \text{mol}^{-1}\ \cancel{\text{K}^{-1}})(293\ \cancel{\text{K}})$$
$$n = 8.77 \times 10^{-5}\text{mol}$$

The molar mass of the solute is the number of grams of solute per mole of solute:

$$\text{Molar mass} = \frac{0.122\ \text{g}}{8.77 \times 10^{-5}\ \text{mol}} = 1.39 \times 10^{3}\ \text{g mol}^{-1}$$

Is the Answer Reasonable? In using Equation 13.18, it is essential that the pressure be in atmospheres when using $R = 0.0821$ L atm mol^{-1} K^{-1}. If all the units cancel correctly (and they do), we've computed the number of moles correctly. The moles of solute is approximately 10×10^{-5}, or 1×10^{-4}. Dividing the mass, roughly 0.12 g, by 1×10^{-4} mol gives 0.12×10^{4} g per mol or 1.2×10^{3} g per mol, which is close to the value we found.

Practice Exercises

13.23 | Estimate the molecular mass of a protein when 137.2 mg of the protein, dissolved in 100.0 mL of water at 4 °C, supports a column of water that is 6.45 cm high. (*Hint:* The answer should be very large. Don't forget to convert cm of water to atmospheres of pressure.)

13.24 | A solution of a carbohydrate prepared by dissolving 72.4 mg in 100 mL of solution has an osmotic pressure of 25.0 torr at 25.0 °C. What is the molecular mass of the compound?

Colligative Properties of Ionic Solutes

The molal freezing point depression constant for water is 1.86 °C m^{-1}. So you might think that a 1.00 m solution of NaCl would freeze at −1.86 °C. Instead, it freezes at −3.37 °C. This greater depression of the freezing point by the salt, which is almost twice 1.86 °C, is not hard to understand if we remember that colligative properties depend on the concentrations of *particles*. We know that NaCl(s) dissociates into ions in water.

$$\text{NaCl}(s) \longrightarrow \text{Na}^{+}(aq) + \text{Cl}^{-}(aq)$$

If the ions are truly separated, 1.00 m NaCl actually has a concentration of dissolved solute particles that is 2.00 m, twice the given molal concentration. Theoretically, 1.00 m NaCl should freeze at $2 \times 1.00\ m \times (-1.86\ °\text{C}\ m^{-1})$ or −3.72 °C. (Why it actually freezes a little higher than this, at −3.37 °C, will be discussed shortly.)

If we made up a solution of 1.00 m $(\text{NH}_4)_2\text{SO}_4$, we would have to consider the following dissociation.

$$(\text{NH}_4)_2\text{SO}_4(s) \longrightarrow 2\text{NH}_4{}^{+}(aq) + \text{SO}_4{}^{2-}(aq)$$

One mole of $(\text{NH}_4)_2\text{SO}_4$ can give a total of 3 mol of ions (2 mol of $\text{NH}_4{}^{+}$ and 1 mol of $\text{SO}_4{}^{2-}$). We would expect the freezing point of a 1.00 m solution of $(\text{NH}_4)_2\text{SO}_4$ to be $3 \times 1.00\ m \times (-1.86\ °\text{C}\ m^{-1}) = -5.58\ °\text{C}$.

When we want to roughly *estimate* a colligative property of a solution of an electrolyte, we recalculate the solution's molality using an assumption about the way the solute dissociates or ionizes. For example, with ionic substances we may assume 100% dissociation, although we will see shortly that this assumption is only true for very dilute solutions.

Example 13.12

Estimating the Freezing Point of a Salt Solution

Estimate the freezing point of aqueous 0.106 m MgCl_2, assuming that it dissociates completely.

Analysis: Equation 13.15 relates a change in freezing temperature to molality, but we now have to include the fact that our solute dissociates into three particles, one Mg^{2+} and two Cl^- ions. Including this additional information allows us to make a better estimate of the freezing point.

Assembling the Tools: We will use the basic freezing point equation, with the K_f for water from Table 13.3.

$$\Delta T_f = (1.86\ ^\circ\text{C}\ m^{-1})\ m$$

However, our molality must be the molality of all ions, not the molality of the salt.

$$\text{MgCl}_2(s) \longrightarrow \text{Mg}^{2+}(aq) + 2\text{Cl}^-(aq)$$

Solution: Because 1 mol of $MgCl_2$ gives 3 mol of ions, the effective (assumed) molality of ions in the solution is three times the molality of the salt, 0.106 *m*.

$$\text{Effective molality} = (3)(0.106\ m) = 0.318\ m$$

The effective molarity is often called the osmolarity in the biological sciences.

Now we can use Equation 13.15.

$$\begin{aligned}\Delta T_f &= (1.86\ ^\circ\text{C}\ m^{-1})(0.318\ m)\\ &= 0.591\ ^\circ\text{C}\end{aligned}$$

The freezing point is depressed below 0.000 °C by 0.591 °C, so we calculate that this solution freezes at −0.591 °C.

Is the Answer Reasonable? The molality of particles, as recalculated, is roughly 0.3, so 3/10th of 1.86 (call it 2) is about 0.6, which, after we add the unit, °C, and subtract from 0 °C gives −0.6 °C, which is close to the answer.

Practice Exercises

13.25 | Calculate the freezing point of aqueous 0.237 *m* LiCl on the assumption that it is 100% dissociated. Calculate the freezing point if the percent dissociation is 0%. (*Hint:* Recall the relationships developed in Section 13.7.)

13.26 | Determine the freezing point of aqueous solutions of $MgSO_4$ that are (a) 0.100 *m*, (b) 0.0100 *m*, and (c) 0.00100 *m*. Which of these could be measured with your laboratory thermometer that is graduated in one °C intervals?

Analyzing and Solving Multi-Concept Problems

A sample of a recently synthesized compound was analyzed by a technician but the analysis of the data is left to you. The technician took 15.00 mL of the substance, which has a density of 1.106 g/mL, and burned it in an excess of oxygen. The carbon dioxide collected weighed 28.63 grams and the water collected weighed 11.71 grams. In another experiment, 1.395 g of the compound was decomposed by heating strongly in the presence of metallic sodium to destroy the organic material and release any chlorine as chloride ions. Those chloride ions are precipitated with silver nitrate and the result is 2.541 g of AgCl. Finally, 5.41 g of this compound were mixed with 85.0 g of benzene and the freezing point was found to be 3.33 °C. What is the formula for the compound?

Analysis We need to determine the empirical formula for the compound and then the molecular formula. Since several methods were used for the analysis, we should calculate the percent composition of the compound, then the empirical formula, and finally the molecular formula. To summarize, for the first part we will use the analytical data to compute the percentage of each element in the compound. In the second part we determine the empirical formula. In the third part we find the molar mass from the freezing point depression. The fourth part will be the determination of the actual formula.

PART 1

Assembling the Tools We need to use the available data to determine the percentage of carbon, hydrogen, and chlorine in the compound. The percentages are calculated as follows:

$$\%\ \text{composition} = \frac{\text{mass of element}}{\text{mass of sample}} \times 100\%$$

We determine the mass of sample from the volume by using the density as a conversion factor as described in Chapter 2. Then we can use the stoichiometric conversions in Chapter 4.

Solution Our first step is to convert the volume of our sample to the mass, using the density,

$$15.00\ \cancel{\text{mL}} \times \frac{1.106\ \text{g}}{1\ \cancel{\text{mL}}} = 16.59\ \text{g sample}$$

Next we can convert the mass of CO_2 to the mass of carbon,

$$28.63\ \cancel{\text{g CO}_2} \times \frac{12.011\ \text{g C}}{44.01\ \cancel{\text{g CO}_2}} = 7.807\ \text{g C}$$

and convert the mass of H_2O to the mass of H,

$$11.71\ \cancel{\text{g H}_2\text{O}} \times \frac{1\ \cancel{\text{mol H}_2\text{O}}}{18.015\ \cancel{\text{g H}_2\text{O}}} \times \frac{2\ \cancel{\text{mol H}}}{1\ \cancel{\text{mol H}_2\text{O}}} \times \frac{1.008\ \text{g H}}{1\ \cancel{\text{mol H}}} = 1.310\ \text{g H}$$

We then calculate the percentage of C and H

$$\%\ \text{C} = \frac{7.807\ \text{g C}}{16.59\ \text{g sample}} \times 100\% = 47.06\%\ \text{C}$$

$$\%\ \text{H} = \frac{1.310\ \text{g H}}{16.59\ \text{g sample}} \times 100\% = 7.900\%\ \text{H}$$

The mass of chlorine is calculated as

$$2.541\ \cancel{\text{g AgCl}} \times \frac{1\ \cancel{\text{mol AgCl}}}{143.32\ \cancel{\text{g AgCl}}} \times \frac{1\ \cancel{\text{mol Cl}}}{1\ \cancel{\text{mol AgCl}}} \times \frac{35.45\ \text{g Cl}}{1\ \cancel{\text{mol Cl}}} = 0.6285\ \text{g Cl}$$

The percentage of chloride in the sample is

$$\%\text{Cl} = \frac{0.6285\ \text{g Cl}}{1.395\ \text{g sample}} \times 100\% = 45.04\%\ \text{Cl}$$

The percentages add up to almost 100%, and we can conclude that there are no other elements in the compound except C, H, and Cl.

PART 2

Assembling the Tools We convert the percentages to mass units, assuming a 100 g sample. Next, we use the stoichiometric conversions from mass to moles for the elements in the compound. Last, we use the procedures in Section 4.3 to determine the empirical formula.

Solution We will convert the percentages to mass and then to moles for the three elements,

$$47.06\ \cancel{\text{g C}} \times \frac{1\ \text{mol C}}{12.011\ \cancel{\text{g C}}} = 3.918\ \text{mol C}$$

$$7.900\ \cancel{\text{g H}} \times \frac{1\ \text{mol H}}{1.008\ \cancel{\text{g H}}} = 7.837\ \text{mol H}$$

$$45.04\ \cancel{\text{g Cl}} \times \frac{1\ \text{mol Cl}}{35.45\ \cancel{\text{g Cl}}} = 1.271\ \text{mol Cl}$$

We divide each of the quantities above by the smallest value, 1.271, to get

3.04 mol C, 6.17 mol H, and 1.00 mol Cl

These numbers are close enough to integers to write

$$3 \text{ mol C}, \quad 6 \text{ mol H}, \quad \text{and} \quad 1 \text{ mol Cl}$$

The empirical formula is C_3H_6Cl.

PART 3

Assembling the Tools We need to determine the molar mass from the freezing point depression, Equation 13.15. The freezing point of pure benzene from Table 13.3 is 5.45 °C and the freezing point depression constant is 5.07 °C m^{-1}. We can calculate the molality, then the molar mass.

Solution The measured freezing point is 3.33 °C and ΔT_f is 2.12 °C. Using Equation 13.15 we write

$$\Delta T_f = 2.12\ °\text{C} = (5.07\ °\text{C}\ m^{-1})\ m$$

The molality is 0.418.
We can expand the definition of molality as

$$\text{molality} = \frac{\text{moles of solute}}{\text{kg solvent}} = \frac{\text{g solute/molar mass solute}}{\text{kg solvent}}$$

Entering the known data we get

$$0.418\ m = \frac{5.41 \text{ g solute/molar mass of solute}}{0.085 \text{ kg solvent}}$$

and the molar mass of the solute is

$$\text{molar mass of solute} = \frac{5.41 \text{ g solute}}{0.085 \text{ kg solvent} \times 0.418\ m} = 152.2 \text{ g mol}^{-1}$$

PART 4

Assembling the Tools Now we need to determine the molecular formula using the method described in Section 4.3. We need to take the molar mass of the molecular formula and divide it by the molar mass of the empirical formula to determine how many empirical formula units are in the complete molecular formula.

Solution We divide the molar mass by the empirical formula mass, and the result should be a small whole number that is the multiplication factor for the formula's subscripts,

$$\frac{152.2}{77.5} = 1.96 = 2$$

Therefore, we multiply all of the subscripts in the empirical formula by 2 and get the formula $C_6H_{12}Cl_2$.

Are the Answers Reasonable? In a four-part problem, if we end up with a simple, whole-number ratio after many calculations, it gives us confidence that the preceding parts were correct. Looking more closely at the first part, the percentage of hydrogen is the smallest, as we expect for the lightest element. In Part 2 we get numbers that are very close to whole-number ratios for the formula. In Part 3 we find a molar mass that is neither extremely small or large, as expected for a freezing point depression experiment. Each part seems to have reasonable results, and we are confident that the final result is correct.

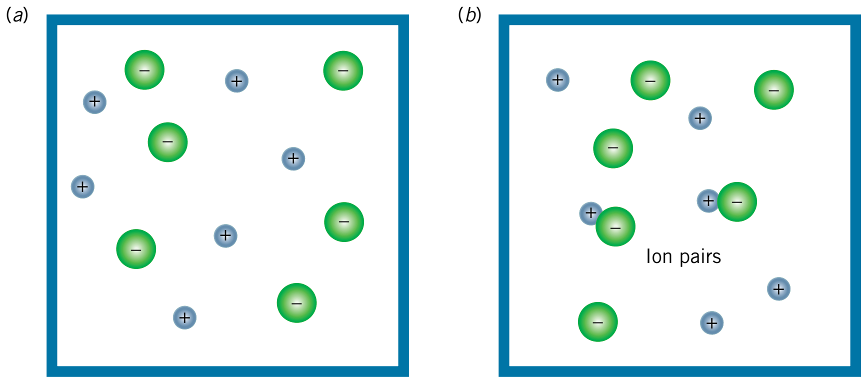

Figure 13.22 | **Ion pairs in a solution of NaCl.** (*a*) If NaCl were completely dissociated in water, the Na^+ and Cl^- ions would be totally independent.
(*b*) Interionic attractions cause some ions to group together as ion pairs, which reduces the total number of independent particles in the solution. In this diagram, two ion pairs are shown. (Water molecules are not shown for clarity.)

Ion Pairing

Experiments show that neither the 1.00 *m* NaCl nor the 1.00 *m* $(NH_4)_2SO_4$ solution described earlier in this section freezes quite as low as calculated. Our assumption that an electrolyte separates *completely* into its ions is incorrect. Some oppositely charged ions exist as very closely associated pairs, called **ion pairs**, which behave as single "molecules" (Figure 13.22). Clusters larger than two ions probably also exist. The formation of ion pairs and clusters makes the actual *particle* concentration in a 1.00 *m* NaCl solution somewhat less than 2.00 *m*. As a result, the freezing point depression of 1.00 *m* NaCl is not quite as large as calculated on the basis of 100% dissociation.

■ "Association" is the opposite of dissociation. It is the coming together of particles to form larger particles.

As solutions of electrolytes are made more and more *dilute*, the observed and calculated freezing points come closer and closer together. At greater dilutions, the **association** (coming together) of ions is less and less a complication because the ions collide less frequently, resulting in relatively fewer ion pairs. Generally, solutes behave more and more as if they were 100% separated into their ions in ever more dilute solutions.

Chemists compare the degrees of dissociation of electrolytes at different dilutions by a quantity called the **van't Hoff factor, *i***. It is the ratio of the observed freezing point depression to the value calculated on the assumption that the solute dissolves as a nonelectrolyte.

$$i = \frac{(\Delta T_f)_{\text{measured}}}{(\Delta T_f)_{\text{calculated as a nonelectrolyte}}}$$

The predicted van't Hoff factor, *i*, is 2 for NaCl, KCl, and $MgSO_4$, which break up into two ions on 100% dissociation. For K_2SO_4, the theoretical value of *i* is 3 because one K_2SO_4 unit gives 3 ions. The actual van't Hoff factors for several electrolytes at different dilutions are given in Table 13.4. Notice that with decreasing concentration (that is, at higher dilutions) the experimental van't Hoff factors agree better with their corresponding hypothetical van't Hoff factors.

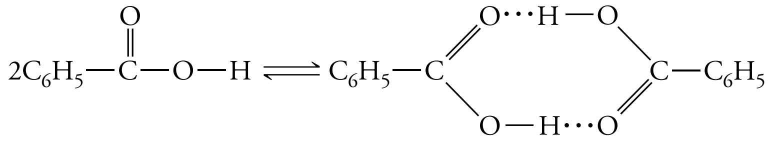
The increase in the percentage dissociation that comes with greater dilution is not the same for all salts. In going from concentrations of 0.1 to 0.001 *m*, the increase in percentage dissociation of KCl, as measured by the change in *i*, is only about 7%. However, for K_2SO_4 the increase for the same dilution is about 22%, a difference caused by the anion, SO_4^{2-}. It has twice the charge as the anion in KCl, and so the SO_4^{2-} ion attracts K^+ more strongly than can Cl^-. Hence, letting an ion of 2− charge and an ion of 1+ charge get farther apart by dilution has a greater effect on their acting independently than giving ions of 1− and 1+ charge more room. When *both* cation and anion are doubly charged, the improvement in percent dissociation with dilution is even greater. We can see from Table 13.4 that there is an almost 50% increase in the value of *i* for $MgSO_4$ as we go from a 0.1 to a 0.001 *m* solution.

Table 13.4 Van't Hoff Factors versus Concentration

	Van't Hoff Factor, *i*			
	Molal Concentration (mol salt/kg water)			Value of *i* if 100% Dissociation Occurred
Salt	0.1	0.01	0.001	
NaCl	1.87	1.94	1.97	2.00
KCl	1.85	1.94	1.98	2.00
K_2SO_4	2.32	2.70	2.84	3.00
$MgSO_4$	1.21	1.53	1.82	2.00

Molecular Association

Some molecular solutes produce *weaker* colligative effects than their molal concentrations would lead us to predict. These unexpectedly weak colligative properties are often evidence that solute molecules are clustering or associating in solution. For example, when dissolved in benzene, benzoic acid molecules associate as **dimers**. They are held together by hydrogen bonds, indicated by the dotted lines in the following equation.



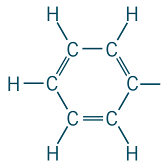
benzoic acid

benzoic acid dimer

■ *Di-* signifies two, so a dimer is the result of the combination of two single molecules.

Because of association, the depression of the freezing point of a 1.00 *m* solution of benzoic acid in benzene is only about one-half the calculated value. By forming a dimer, benzoic acid has an effective molecular mass that is twice as much as normally calculated. The larger effective molecular mass reduces the molal concentration of particles by half, and the effect on the freezing point depression is reduced by one-half.

■ C_6H_5–, called the phenyl group in organic chemistry, has the structure



13.8 | Heterogeneous Mixtures

Up to now we have discussed true solutions, mixtures that have a single phase and are uniform throughout. Heterogeneous mixtures, often called **dispersions**, have two or more phases or are not homogeneous. These are very important chemically since many industrial reactions can be described as heterogeneous and because many consumer products are dispersions of various types. We will consider two types of these dispersions, **suspensions** and **colloids**.

Suspensions

A suspension is characterized by the presence of relatively large particles mixed in a solvent. To prepare such a suspension, a substance can be mixed uniformly in a solvent, or dispersing medium, by mechanical means such as mixing or shaking. However, once the mixing process is stopped, the particles in a suspension will start to coalesce, due to attractive forces, into large particles that will separate into two phases. In other suspensions, such as fine sand dispersed in water, the two phases separate due to gravitational forces.

You may be most familiar with suspensions as common drugs. Solid magnesium hydroxide is suspended in water in a preparation called milk of magnesia. Many antibiotics are aqueous suspensions that you must "shake well before dispensing." Some salad dressings, such as those shown in the opening photograph, fall into the same category and will separate quickly into oil and vinegar layers soon after shaking. The settling process in some suspensions can be accelerated by centrifugation where the gravitational forces are increased many-fold by the high-speed rotation of the centrifuge.

Suspensions involving the gas phase are also familiar. Soot from fires is one example.[7] The result often is a layer of black grime that covers everything outdoors. Dust, some of which is ascribed to meteorites, that settles out of the air and fine droplets of water within a fog are examples of a solid and a liquid suspended in the gas phase respectively. Air bubbles within whipped cream or whipped egg whites are examples of a suspension of a gas in a liquid that will eventually separate, if not eaten first. In whipped cream and egg whites, the suspensions are relatively long lasting; the high viscosity hinders the ability of the gas bubbles to coalesce and form separate phases.

---

[7] Coal- and oil-fired power plants used to be the major sources of soot and other particulates. Modern electrostatic precipitators and scrubbers remove a large majority of these particulates.

Colloids

When the particles in a suspension are very small, Brownian motion (see Section 3.6) keeps them from settling. These mixtures that do not settle, or separate into different phases, are called colloidal dispersions. Generally a colloid particle must have at least one dimension in the range of 1 to 1000 nm. Some of the particles of water in fog and soot in smoke, mentioned previously, qualify as true colloidal substances and do not separate. A small amount of starch dissolved in water is an example of a colloid in an aqueous system, also called a sol. Table 13.5 lists examples of colloidal mixtures and classifies them based on the dispersed phase (i.e., the colloid) and the dispersing phase (the solvent). In many mixtures the sizes of colloidal particles makes them invisible to the naked eye. Although a colloidal mixture may look very much like a true solution, the colloidal particles, with dimensions similar to the wavelengths of visible light, will scatter light. This scattering is called the **Tyndall effect** and can be observed by shining a narrow beam of light through the colloidal mixture. A dramatic illustration of the Tyndall effect is shown in Figure 13.23, where red laser light shines through a series of test tubes.

■ John Tyndall, 1820–1893, a prominent physicist, succeeded Michael Faraday as the Fullerian Professor of Chemistry at the Royal Institution of Great Britain.

Figure 13.23 shows us some colloidal mixtures that look like true solutions. However, other colloidal dispersions, called **emulsions,** may look more like milk or whipped cream. In an emulsion the dispersing phase is a liquid and, often, the concentration of colloidal particles is very high. This means that colloidal particles may have a greater probability of colliding and coalescing, eventually into two phases.

Chemists have devised a variety of strategies to slow or even stop the coalescing of colloidal particles in emulsions. In recent chapters we have learned that we can reduce the frequency of collisions in the liquid phase by (a) lowering the temperature, (b) raising the viscosity, or (c) decreasing attractive forces and increasing repulsive forces. Let's look at an example of each.[8] Old-time ice cream is an emulsion of milk, eggs, cream, sugar, and flavorings. In the case of ice cream, it is kept frozen and the colloidal particles rarely collide. In the whipped cream example, the usually fluid cream has colloidal-size air bubbles incorporated into it, resulting in a very viscous product. Once again, the limited mobility of the colloidal particles keeps them from coalescing. Figure 13.24 illustrates the microscopic view of two types of emulsion: mayonnaise, a liquid–liquid emulsion, and margarine, a liquid–solid emulsion.

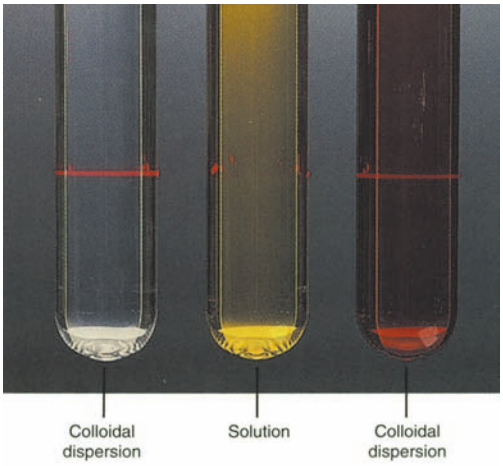


Figure 13.23 | **The Tyndall effect.** Colloidal solutions may appear as true solutions. The first tube contains a colloidal starch dispersion, the second is a true solution of Na_2CrO_4, and the third tube is a colloidal dispersion of Fe_2O_3. A red laser beam passes through all three tubes, and the colloidal dispersions scatter the red light towards the viewer while the true solution does not. *(OPC, Inc.)*

Table 13.5 **Colloidal Systems**

Type	Dispersed Phase[a]	Dispersing Medium	Common Examples
Foam	Gas	Liquid	Soapsuds, whipped cream
Solid foam	Gas	Solid	Pumice, marshmallow
Liquid Aerosol	Liquid	Gas	Mist, fog, clouds, air pollutants
Emulsion	Liquid	Liquid	Cream, mayonnaise, milk
Solid emulsion	Liquid	Solid	Butter, cheese
Smoke	Solid	Gas	Dust, particulates in smog, aerogels
Sol (Colloidal Dispersion)	Solid	Liquid	Starch in water, paint, jellies[b]
Solid sol	Solid	Solid	Alloys, pearls, opals

[a] Colloidal particles are in the dispersed phase.

[b] Semisolid or semirigid sols, such as gelatins and jellies, are called gels.

---

[8] Each of these examples actually uses a combination of all three strategies, but we focus on the main concept for each one.

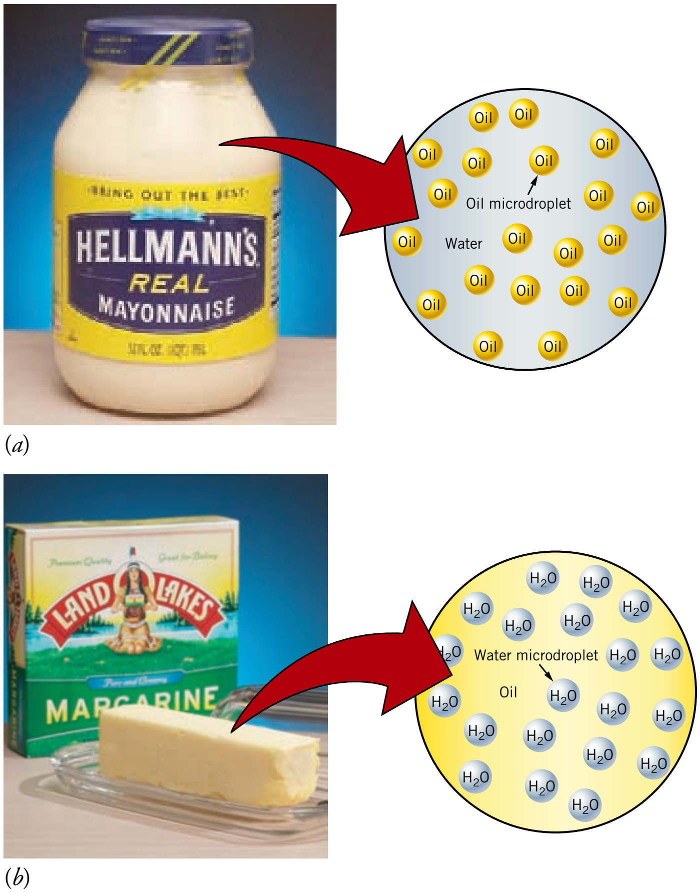

Figure 13.24 | **Two common emulsions.** (*a*) The dispersion of oil in water occurs when mayonnaise is prepared. (*b*) Low-calorie and low-fat butter is often made by dispersing water in the solid butterfat. *(Andy Washnik)*

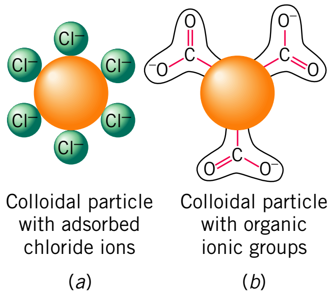
The major method for stabilizing most commercial emulsions is to incorporate into one or both phases an electrical charge that keeps the colloidal particles apart. Surfactants such as sodium stearate are long molecules with a charged end and an uncharged hydrocarbon end. The charged end will dissolve in water and is said to be **hydrophilic**, while the hydrocarbon end dissolves more readily in oils and is called **hydrophobic.** When sodium stearate is added to an oil–water emulsion the hydrophobic end dissolves in the oil while the hydrophilic end extends into the aqueous phase. The result is often a spherical, negatively charged particle called a **micelle**. The negative charge of one micelle repels the negative charges of other micelles. The result is that micelles will not coalesce into separate oil and water phases. Proteins can also adsorb to oil particles and provide a charged surface. Figure 13.25 illustrates how adsorbed layers can produce charged colloidal particles. An emulsion stabilized in this fashion can be separated into two phases by adding an acid or base to neutralize the charged groups. This is called "breaking" an emulsion.

In crystals of small inorganic molecules a stabilizing charged layer can be established by an excess of one of the crystal's ions. For example, if lead(II) ions are precipitated with a large excess of chloride ions, the excess chloride ions will adsorb to the surface of the lead(II) chloride crystals in what is called the primary adsorbed layer. Since the primary adsorbed layer consists of chloride ions that have a negative charge, the tiny colloidal particles will not coalesce into larger crystals that can be collected by filtration. Figure 13.25 can also be used to visualize this system. Although stabilizing an emulsion is often a desired result in commercial preparations, here we see that it may also be a problem. The effect of the adsorbed layer can be minimized by having only a small excess of chloride ions during precipitation.

Modern nanoscience is very interested in nanometer-size particles that have unusual properties. Colloidal gold is a nanoparticle that may be useful for drug delivery to tumors. Interestingly, colloidal gold was first used by medieval artists who transcribed elegantly "illuminated" bibles, where this nanoparticle exhibits many different colors. Colloidal, magnetic, iron particles have many interesting properties, as do the fullerenes, substances related to the C_{60} allotrope of carbon that we discuss in Chapter 10 on page 457.



Colloidal particle with adsorbed chloride ions
(*a*)

Colloidal particle with organic ionic groups
(*b*)

Figure 13.25 | **Stabilizing colloidal dispersions.** Colloidal particles that may tend to coalesce can be stabilized by acquiring an electrical charge. (*a*) Inorganic precipitates can have an adsorbed layer of ions that prevents them from coalescing into particles that can be filtered. (*b*) Colloidal particles can have charged groups that give it an overall electrical charge, or charged particles can be adsorbed to the surface of a colloidal particle with the same effect.

Summary

Solutions. Polar or ionic solutes generally dissolve well in polar solvents such as water. Nonpolar, molecular solutes dissolve well in nonpolar solvents. These observations are behind the "**like dissolves like**" **rule**. Nature's driving force for establishing the more statistically probable mixed state and intermolecular attractions are the two major factors in the formation of a solution. When both solute and solvent are nonpolar, nature's tendency toward the more probable mixed state dominates because intermolecular attractive forces are weak. Ion–dipole attractions and the **solvation** or **hydration** of dissolved species are major factors in forming solutions of ionic or polar solutes in something polar, like water.

Heats of Solution. The **molar enthalpy of solution** of a solid in a liquid, also called the **heat of solution,** is calculated as the **lattice energy** subtracted from the **solvation energy** (or, when water is the solvent, the **hydration energy**). The lattice energy is the decrease in the potential energy of the system that would occur if the molecules or ions of the solute came together to form the solid solute crystals. The solvation energy corresponds to the potential energy lowering that occurs in the system from the subsequent attractions of these particles to the solvent molecules as intermingling occurs.

When liquids dissolve in liquids, an **ideal solution** forms if the potential energy increase needed to separate the molecules equals the energy lowering as the separated molecules come together. Usually, some net energy exchange occurs, however, because few solutions are ideal.

When a gas dissolves in a gas, the energy cost to separate the particles is virtually zero, because they're already separated. They remain separated in the gas mixture, so the net enthalpy of solution is very small if not zero. When a gas dissolves in an organic solvent, the solution process is often endothermic. When a gas dissolves in water, the solution process is often exothermic.

Pressure and Gas Solubility. At pressures not too much different from atmospheric pressure, the solubility of a gas in a liquid is directly proportional to the partial pressure of the gas—**Henry's law**.

Concentration Expressions. To study and use colligative properties, a solution's concentration ideally is expressed either in mole fractions or as a **molal concentration,** or **molality**. The **molality** of a solution, m, is the ratio of the number of moles of solute to the kilograms of *solvent* (not solution, but solvent). **Mass fractions** and **mass percents** are concentration expressions used often for chemicals when direct information about number of moles of solutes is not considered important. Mole fraction, molality, and mass percent are temperature-independent concentration expressions.

Colligative Properties. **Colligative properties** are those that depend on the ratio of the particles of the solute to the molecules of the solvent. These properties include the **lowering of the vapor pressure,** the **depression of a freezing point,** the **elevation of a boiling point,** and the **osmotic pressure** of a solution.

According to **Raoult's law,** the vapor pressure of a solution of a nonvolatile (molecular) solute is the vapor pressure of the pure solvent times the mole fraction of the solvent. An alternative expression of this law is that the *change* in vapor pressure caused by the solute equals the mole fraction of the solute times the pure solvent's vapor pressure. When the components of a solution are volatile liquids, then Raoult's law calculations find the *partial pressures* of the vapors of the individual liquids. The sum of the partial pressures equals the total vapor pressure of the solution.

An *ideal solution* is one that would obey Raoult's law exactly and in which all attractions between molecules are equal. An ideal solution has $\Delta H_{\text{soln}} = 0$. Heats of solution of nonideal mixtures may be exothermic or endothermic and these correspond to vapor pressures that are less or greater than expected from Raoult's law, respectively.

In proportion to its molal concentration, a solute causes a **freezing point depression** and a **boiling point elevation.** The proportionality constants are the **molal freezing point depression constant** and the **molal boiling point elevation constant,** and they differ from solvent to solvent. Freezing point and boiling point data from a solution made from known masses of both solute and solvent can be used to calculate the molecular mass of a solute.

When a solution is separated from the pure solvent (or from a less concentrated solution) by an *osmotic membrane*, **osmosis** occurs, which is the net flow of solvent into the more concentrated solution. The back pressure required to prevent osmosis is called the solution's **osmotic pressure,** which, in a dilute aqueous solution, is proportional to the product of the Kelvin temperature and the molar concentration. The proportionality constant is R, the ideal gas constant, and the equation relating these variables is $\Pi = MRT$.

When the membrane separating two different solutions is a *dialyzing membrane*, it permits **dialysis,** the passage not only of solvent molecules but also of small solute molecules or ions. Only very large molecules are denied passage.

Colligative Properties of Electrolytes. Because an electrolyte releases more ions in solution than indicated by the molal (or molar) concentration, a solution of an electrolyte has more pronounced colligative properties than a solution of a molecular compound at the same concentration. The dissociation of a strong electrolyte approaches 100% in very dilute solutions, particularly when both ions are singly charged. Weak electrolytes provide solutions more like those of nonelectrolytes.

The ratio of the value of a particular colligative property (e.g., ΔT_f) to the value expected if there were no dissociation is the **van't Hoff factor, i.** A solute whose formula unit breaks into two ions, like NaCl or $MgSO_4$, would have a van't Hoff factor of 2 if it were 100% dissociated. Observed van't Hoff factors are less than the theoretical values because of the formation of **ion pairs,** brought about by **association** of ions in solution. The van't Hoff factors approach those corresponding to 100% dissociation only as the solutions are made more and more dilute.

Heterogeneous Mixtures. **Suspensions** are mixtures where the particles are so large that they begin precipitation or coalescing as soon as the mixing process is stopped. The result is the formation of two or more phases. **Colloidal mixtures** are composed of particles with the largest dimension being 1000 nm. Colloidal mixtures do not settle and can be identified using the **Tyndall effect**. A special colloidal mixture called an **emulsion** is a mixture that can be stabilized by electrical charges or **hydrophobic** and **hydrophilic repulsions.** These factors keep the phases from coalescing. **Hydrophobic** and **hydrophilic** properties of surfactants often create **micelles** that stabilize emulsions.

Tools for Problem Solving

The compilation below lists the tools you have learned in this chapter that are applicable to problem solving. Review them if necessary, and refer to them when working on the Review Problems that follow.

“Like dissolves like” rule (page 587)

This rule uses the polarity and strengths of attractive forces, along with chemical composition and structure, to predict whether two substances can form a solution.

Henry’s law (page 595)

The solubility of a gas at a given pressure can be approximated from its solubility at another pressure by using the Henry’s law equation.

$$C_{\text{gas}} = k_{\text{H}} P_{\text{gas}}$$

Mass fraction; percentage by mass (page 597)

These concentration terms may be used as conversion factors as well as representing the concentration of a solution

$$\text{mass fraction} = \frac{\text{mass of solute}}{\text{mass of solution}}$$

$$\text{percentage by mass} = \%(\text{w/w}) = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100\%$$

Molal concentration (page 599)

Molality is a temperature-independent concentration expression, often used in experiments where the temperature may be varied.

$$\text{molality} = \frac{\text{moles of solute}}{\text{kg of solvent}}$$

Raoult’s law (page 604)

Raoult’s law predicts the effect of a nonvolatile solute on the vapor pressure of a solution.

$$P_{\text{solution}} = X_{\text{solvent}} P^{\circ}_{\text{solvent}}$$

A second form of Raoult’s law is used when two volatile solutes, A and B, are mixed (page 607).

$$P_{\text{solution}} = X_A P^{\circ}_A + X_B P^{\circ}_B$$

Freezing point depression and boiling point elevation (page 609)

The freezing point depression and boiling point elevation equations can be used to estimate the changes in freezing and boiling points, respectively. They also provide a method for determining molar masses of non-dissociating solutes.

$$\text{Freezing point depression:} \quad \Delta T_f = K_f m$$

$$\text{Boiling point elevation:} \quad \Delta T_b = K_b m$$

Osmotic pressure (page 614)

The osmotic pressure of a solution can be used to calculate molecular masses from osmotic pressure and concentration data. Note the similarity to the ideal gas law (page 491).

$$\Pi V = nRT \quad \text{or} \quad \Pi = MRT$$

PLUS = *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com.** ILW = An Interactive Learningware solution is available for this problem. OH = An Office Hour video is available for this problem. Review Problems are presented in pairs separated by blue rules. Answers to problems whose numbers appear in blue are given in Appendix B. Review Questions

Why Solutions Form

13.1 Why do two gases spontaneously mix when they are brought into contact?

13.2 When substances form liquid solutions, what two factors are involved in determining the solubility of the solute in the solvent?

13.3 Methanol, CH_3OH, and water are miscible in all proportions. What does this mean? Explain how the OH unit in methanol contributes to this.

13.4 Hexane (C_6H_{12}) and water are immiscible. What does this mean? Explain why they are immiscible in terms of structural features of their molecules and the forces of attraction between them.

13.5 Explain how ion–dipole forces help to bring potassium chloride into solution in water.

13.6 Explain why potassium chloride will not dissolve in carbon tetrachloride, CCl_4.

Heat of Solution

13.7 The value of ΔH_{soln} for a soluble compound is, say, $+26$ kJ mol^{-1}, and a nearly saturated solution is prepared in an insulated container (e.g., a coffee cup calorimeter). Will the system's temperature increase or decrease as the solute dissolves?

13.8 Referring to Question 13.7, which value for this compound would be numerically larger, its lattice energy or its hydration energy?

13.9 Which would be expected to have the larger hydration energy, Al^{3+} or Li^{+}? Why? (Both ions are about the same size.)

13.10 Suggest a reason why the value of ΔH_{soln} for a gas such as CO_2, dissolving in water, is negative.

13.11 The value of ΔH_{soln} for the formation of an acetone–water solution is negative. Explain this in general terms using intermolecular forces of attraction.

13.12 The value of ΔH_{soln} for the formation of an ethanol–hexane solution is positive. Explain this in general terms that involve intermolecular forces of attraction.

13.13 When a certain solid dissolves in water, the solution becomes cool. Is ΔH_{soln} for this solute positive or negative? Explain your reasoning. Is the solubility of this substance likely to increase or decrease with increasing temperature? Explain your answer using Le Châtelier's principle.

13.14 If the value of ΔH_{soln} for the formation of a mixture of two liquids *A* and *B* is zero, what does this imply about the relative strengths of *A*–*A*, *B*–*B*, and *A*–*B* intermolecular attractions?

Temperature and Solubility

13.15 If a saturated solution of NH_4NO_3 at 75 °C is cooled to 15 °C, how many grams of solute will separate if the quantity of the solvent is 125 g? (Use the data in Figure 13.10.)

13.16 Anglers know that on hot summer days, the largest fish will be found in deep sinks in lake bottoms. Use the temperature dependence of the density of water and the temperature dependence of the oxygen solubility in water to explain why.

Pressure and Solubility

13.17 What is Henry's law?

13.18 Mountain streams often contain fewer living things than equivalent streams at sea level. Give one reason why this might be true in terms of oxygen solubilities at different pressures.

13.19 Why is ammonia so much more soluble in water than nitrogen? Would you expect hydrogen chloride gas to have a high or low solubility in water? Explain your answers to both questions.

13.20 Why does a bottled carbonated beverage fizz when you take the cap off?

Expressions of Concentration

13.21 Write the definition for each of the following concentration units: **(a)** mole fraction, **(b)** mole percent, **(c)** molality, **(d)** percent by mass. What are the maximum possible values for the units in **(a)**, **(b)**, and **(d)**?

13.22 How does the molality of a solution vary with increasing temperature? How does the molarity of a solution vary with increasing temperature?

13.23 Suppose a 1.0 *m* solution of a solute is made using a solvent with a density of 1.15 g/mL. Will the molarity of this solution be numerically larger or smaller than 1.0? Justify your conclusion mathematically.

Colligative Properties

13.24 What specific fact about a physical property of a solution must be true to call it a colligative property?

13.25 What kinds of data would have to be obtained to find out whether a solution of two miscible liquids is almost exactly an ideal solution?

13.26 When octane is mixed with methanol, the vapor pressure of the octane over the solution is higher than what we would calculate using Raoult's law. Why? Explain the discrepancy in terms of intermolecular attractions.

13.27 Explain why a nonvolatile solute dissolved in water makes the system have **(a)** a higher boiling point than water, and **(b)** a lower freezing point than water.

13.28 Why do we call dialyzing and osmotic membranes *semipermeable*? What is the opposite of *permeable*?

13.29 What is the key difference between dialyzing and osmotic membranes?

13.30 At a molecular level, explain why, in osmosis, there is a net migration of solvent from the side of the membrane less concentrated in solute to the side more concentrated in solute.

13.31 Two glucose solutions of unequal molarity are separated by an osmotic membrane. Which solution will *lose* water, the one with the higher molarity or the one with the lower molarity?

13.32 Which aqueous solution has the higher osmotic pressure, 10% glucose, $C_6H_{12}O_6$, or 10% sucrose, $C_{12}H_{22}O_{11}$? (Both are molecular compounds.)

13.33 When a solid is *associated* in a solution, what does this mean? What difference does it make to expected colligative properties?

13.34 What is the difference between a *hypertonic* solution and a *hypotonic* solution?

Colligative Properties of Electrolytes

13.35 Why are colligative properties of solutions of ionic compounds usually more pronounced than those of solutions of molecular compounds of the same molalities?

13.36 What is the van't Hoff factor? What is its expected value for all nondissociating molecular solutes? If its measured value is slightly larger than 1.0, what does this suggest about the solute? What is suggested by a van't Hoff factor of approximately 0.5?

13.37 Which aqueous solution, if either, is likely to have the higher boiling point, 0.50 *m* NaI or 0.50 *m* Na_2CO_3?

Heterogeneous Mixtures

13.38 Determine whether each of the following is likely to be a true solution, a suspension, or a colloidal mixture: **(a)** orange juice, **(b)** apple juice, **(c)** perfume, **(d)** tea, **(e)** tea with lemon juice, **(f)** canned gravy. If you have a laser pointer, how can you confirm your answers?

13.39 Can sodium stearate stabilize a water in oil emulsion? Explain your conclusion.

13.40 Addition of a neutral salt to a colloidal precipitate such as the $BaSO_4(s)$ described in the text allows the crystals to grow in size. Develop a hypothesis on why this occurs.

13.41 What is a micelle, and why does it form?

Review Problems

Heat of Solution

13.42 Consider the formation of a solution of aqueous potassium chloride. Write the thermochemical equations for **(a)** the conversion of solid KCl into its gaseous ions and **(b)** the subsequent formation of the solution by hydration of the ions. The lattice energy of KCl is -715 kJ mol^{-1}, and the hydration energy of the ions is -686 kJ mol^{-1}. Calculate the enthalpy of solution of KCl in kJ mol^{-1}.

OH **13.43** For an ionic compound dissolving in water, $\Delta H_{\text{soln}} = -56$ kJ mol^{-1} and the hydration energy is -894 kJ mol^{-1}. Estimate the lattice energy of the ionic compound.

Henry's Law

OH **13.44** The solubility of methane, the chief component of natural gas, in water at 20.0 °C and 1.0 atm pressure is 0.025 g L^{-1}. What is its solubility in water at 1.5 atm and 20.0 °C?

13.45 At 740 torr and 20.0 °C, nitrogen has a solubility in water of 0.018 g L^{-1}. At 620 torr and 20.0 °C, its solubility is 0.015 g L^{-1}. Show that nitrogen obeys Henry's law.

13.46 If the solubility of a gas in water is 0.010 g L^{-1} at 25 °C with the partial pressure of the gas over the solution at 1.0 atm, predict the solubility of the gas at the same temperature but at double the pressure.

13.47 If 100.0 mL of water is shaken with oxygen gas at 1.0 atm it will dissolve 0.0039 g O_2. Estimate the Henry's law constant for oxygen gas in water.

Expressions of Concentration

***13.48** What is the molality of NaCl in a solution that is 3.000 *M* NaCl, with a density of 1.07 g mL^{-1}?

***13.49** A solution of acetic acid, CH_3COOH, has a concentration of 0.143 *M* and a density of 1.00 g mL^{-1}. What is the molality of this solution?

13.50 What is the molal concentration of glucose, $C_6H_{12}O_6$, a sugar found in many fruits, in a solution made by dissolving 24.0 g of glucose in 1.00 kg of water? What is the mole fraction of glucose in the solution? What is the mass percent of glucose in the solution?

13.51 If you dissolved 11.5 g of NaCl in 1.00 kg of water, what would be its molal concentration? What are the mass percent NaCl and the mole percent NaCl in the solution? The volume of this solution is virtually identical to the original volume of the 1.00 kg of water. What is the molar concentration of NaCl in this solution? What would have to be true about any solvent for one of its dilute solutions to have essentially the same molar and molal concentrations?

13.52 A solution of ethanol, CH_3CH_2OH, in water has a concentration of 1.25 *m*. Calculate the mass percent of ethanol.

13.53 A solution of NaCl in water has a concentration of 19.5%. Calculate the molality of the solution.

OH **13.54** A solution of NH_3 in water has a concentration of 7.50% by mass. Calculate the mole percent NH_3 in the solution. What is the molal concentration of the NH_3?

13.55 An aqueous solution of isopropyl alcohol, C_3H_8O, rubbing alcohol, has a mole fraction of alcohol equal to 0.250. What is the percent by mass of alcohol in the solution? What is the molality of the alcohol?

ILW **13.56** Sodium nitrate, $NaNO_3$, is sometimes added to tobacco to improve its burning characteristics. An aqueous solution of $NaNO_3$ has a concentration of 0.363 *m*. Its density is 1.0185 g mL^{-1}. Calculate the molar concentration of $NaNO_3$ and the mass percent of $NaNO_3$ in the solution. What is the mole fraction of $NaNO_3$ in the solution?

13.57 In an aqueous solution of sulfuric acid, the concentration is 1.89 mol% of acid. The density of the solution is 1.0645 g mL^{-1}. Calculate the following: **(a)** the molal concentration of H_2SO_4, **(b)** the mass percent of the acid, and **(c)** the molarity of the solution.

Raoult's Law

OH **13.58** At 25 °C, the vapor pressure of water is 23.8 torr. What is the vapor pressure of a solution prepared by dissolving 65.0 g of $C_6H_{12}O_6$ (a nonvolatile solute) in 150 g of water? (Assume the solution is ideal.)

13.59 The vapor pressure of water at 20 °C is 17.5 torr. A 35% solution of the nonvolatile solute ethylene glycol, $C_2H_4(OH)_2$, in water is prepared. Estimate the vapor pressure of the solution.

13.60 At 25 °C the vapor pressures of benzene (C_6H_6) and toluene (C_7H_8) are 93.4 and 26.9 torr, respectively. A solution made by mixing 35.0 g of benzene and 65.0 g of toluene is prepared. At what applied pressure, in torr, will this solution boil?

13.61 Pentane (C_5H_{12}) and heptane (C_7H_{16}) are two hydrocarbon liquids present in gasoline. At 20.0 °C, the vapor pressure of pentane is 422 torr and the vapor pressure of heptane is 36.0 torr. What will be the total vapor pressure (in torr) of a solution prepared by mixing equal masses of the two liquids?

***13.62** Benzene and toluene help achieve good engine performance from lead-free gasoline. At 40 °C, the vapor pressure of benzene is 184 torr and that of toluene is 58 torr. Suppose you wished to prepare a solution of these liquids that will have a total vapor pressure of 96 torr at 40 °C. What must be the mole percent concentrations of each in the solution?

***13.63** The vapor pressure of pure methanol, CH_3OH, at 33 °C is 164 torr. How many grams of the nonvolatile solute glycerol, $C_3H_5(OH)_3$, must be added to 105 g of methanol to obtain a solution with a vapor pressure of 145 torr?

***13.64** A solution containing 8.3 g of a nonvolatile, nondissociating substance dissolved in 1.00 mol of chloroform, $CHCl_3$, has a vapor pressure of 511 torr. The vapor pressure of pure $CHCl_3$ at the same temperature is 526 torr. Calculate **(a)** the mole fraction of the solute, **(b)** the number of moles of solute in the solution, and **(c)** the molecular mass of the solute.

***13.65** At 21.0 °C, a solution of 18.26 g of a nonvolatile, nonpolar compound in 33.25 g of ethyl bromide, C_2H_5Br, had a vapor pressure of 336.0 torr. The vapor pressure of pure ethyl bromide at this temperature is 400.0 torr. Assuming an ideal solution, what is the molecular mass of the compound?

Freezing Point Depression and Boiling Point Elevation

13.66 How many grams of sucrose ($C_{12}H_{22}O_{11}$) are needed to lower the freezing point of 125 g of water by 3.00 °C?

13.67 To make sugar candy, a concentrated sucrose solution is boiled until the temperature reaches 272 °F. What are the molality and the mole fraction of sucrose in this mixture?

13.68 A solution of 14 g of a nonvolatile, nondissociating compound in 0.10 kg of benzene boils at 81.7 °C. Calculate the molecular mass of the unknown.

OH **13.69** A solution of 12.00 g of an unknown nondissociating compound dissolved in 200.0 g of benzene freezes at 3.45 °C. Calculate the molecular mass of the unknown.

ILW ***13.70** What are the molecular mass and molecular formula of a nondissociating molecular compound whose empirical formula is C_4H_2N if 3.84 g of the compound in 0.500 kg of benzene gives a freezing point depression of 0.307 °C?

***13.71** Benzene reacts with hot concentrated nitric acid dissolved in sulfuric acid to give chiefly nitrobenzene, $C_6H_5NO_2$. A by-product is often obtained, which consists of 42.86% C, 2.40% H, and 16.67% N (by mass). The boiling point of a solution of 5.5 g of the by-product in 45 g of benzene was 1.84 °C higher than that of benzene. **(a)** Calculate the empirical formula of the by-product. **(b)** Calculate a molecular mass of the by-product and determine its molecular formula.

Osmotic Pressure

ILW **13.72** **(a)** Show that the following equation is true.

$$\text{Molar mass of solute} = \frac{(\text{grams of solute})RT}{\Pi V}$$

(b) An aqueous solution of a compound with a very high molecular mass was prepared in a concentration of 2.0 g L^{-1} at 25 °C. Its osmotic pressure was 0.021 torr. Calculate the molecular mass of the compound.

OH **13.73** A saturated solution is made by dissolving 0.400 g of a polypeptide (a substance formed by joining together in a chainlike fashion a number of amino acids) in water to give 1.00 L of solution. The solution has an osmotic pressure of 3.74 torr at 27 °C. What is the approximate molecular mass of the polypeptide?

Colligative Properties of Electrolyte Solutions

13.74 The vapor pressure of water at 20.0 °C is 17.5 torr. At that temperature, what would be the vapor pressure of a solution made by dissolving 23.0 g of NaCl in 0.100 kg of water? (Assume complete dissociation of the solute and an ideal solution.)

13.75 How many grams of $AlCl_3$ would have to be dissolved in 0.150 L of water to give a solution that has a vapor pressure of 38.7 torr at 35 °C? Assume complete dissociation of the solute and ideal solution behavior. (At 35 °C, the vapor pressure of pure water is 42.2 torr.)

OH **13.76** What is the osmotic pressure, in torr, of a 2.0% solution of NaCl in water when the temperature of the solution is 25 °C?

13.77 Below are the concentrations of the most abundant ions in seawater.

Ion	Molality
Chloride	0.566
Sodium	0.486
Magnesium	0.055
Sulfate	0.029
Calcium	0.011
Potassium	0.011
Bicarbonate	0.002

Use these data to estimate the osmotic pressure of seawater at 25 °C in units of atm. What is the minimum pressure in atm needed to desalinate seawater by reverse osmosis?

13.78 What is the expected freezing point of a 0.20 *m* solution of $CaCl_2$? (Assume complete dissociation.)

13.79 The freezing point of a 0.10 *m* solution of mercury(I) nitrate is approximately −0.27 °C. Show that these data suggest that the formula of the mercury(I) ion is Hg_2^{2+}.

Interionic Attractions and Colligative Properties

13.80 The van't Hoff factor for the solute in 0.100 *m* $NiSO_4$ is 1.19. What would this factor be if the solution behaved as if it were 100% dissociated?

13.81 What is the expected van't Hoff factor for K_2SO_4 in an aqueous solution, assuming 100% dissociation?

13.82 A 0.118 *m* solution of LiCl has a freezing point of −0.415 °C. What is the van't Hoff factor for this solute at this concentration?

13.83 What is the approximate osmotic pressure of a 0.118 *m* solution of LiCl at 10 °C? Express the answer in torr. (Use the data in Problem 13.82.)

Additional Problems

***13.84** The "bends" is a medical emergency caused by the formation of tiny bubbles in the blood vessels of divers who rise too quickly to the surface from a deep dive. The origin of the problem is seen in the calculations in this problem. At 37 °C (normal body temperature), the solubility of N_2 in water is 0.015 g L^{-1} when its pressure over the solution is 1 atm. Air is approximately 78 mol% N_2. How many moles of N_2 are dissolved per liter of blood (essentially an aqueous solution) when a diver inhales air at a pressure of 1 atm? How many moles of N_2 dissolve per liter of blood when the diver is submerged to a depth of approximately 100 ft, where the total pressure of the air being breathed is 4 atm? If the diver suddenly surfaces, how many milliliters of N_2 gas, in the form of tiny bubbles, are released into the bloodstream from each liter of blood (at 37 °C and 1 atm)?

OH **13.85** The vapor pressure of a mixture of 0.400 kg of carbon tetrachloride and 43.3 g of an unknown compound is 137 torr at 30 °C. At the same temperature, the vapor pressure of pure carbon tetrachloride is 143 torr, while that of the pure unknown is 85 torr. What is the approximate molecular mass of the unknown? Will our estimate of the molecular mass be too high or too low if the heat of solution is exothermic?

OH **13.86** What is the osmotic pressure in torr of a 0.010 *M* aqueous solution of a molecular compound at 25 °C?

***13.87** Ethylene glycol, $C_2H_6O_2$, is used in many antifreeze mixtures. Protection against freezing to as low as −45 °F is sought.

(a) How many moles of solute are needed per kilogram of water to ensure this protection?

(b) The density of ethylene glycol is 1.11 g mL^{-1}. To how many milliliters of solute does your answer to part **(a)** correspond?

(c) Calculate the number of quarts of ethylene glycol that should be mixed with each quart of water to get the desired protection.

***13.88** The osmotic pressure of a dilute solution of a slightly soluble *polymer* (a compound composed of large molecules formed by linking many smaller molecules together) in water was measured using the osmometer in Figure 13.21. The difference in the heights of the liquid levels was determined to be 1.26 cm at 25 °C. Assume the solution has a density of 1.00 g mL^{-1}. **(a)** What is the osmotic pressure of the solution in torr? **(b)** What is the molarity of the solution? **(c)** At what temperature would the solution be expected to freeze? **(d)** On the basis of the results of these calculations, explain why freezing point depression cannot be used to determine the molecular masses of compounds composed of very large molecules.

13.89 A solution of ethanol, C_2H_5OH, in water has a concentration of 4.613 mol L^{-1}. At 20.0 °C, its density is 0.9677 g mL^{-1}. Calculate the following: **(a)** the molality of the solution and **(b)** the mass percentage of the alcohol in the mixture.

13.90 Consider an aqueous 1.00 *m* solution of Na_3PO_4, a compound with useful detergent properties.

(a) Calculate the boiling point of the solution on the assumption that it does not ionize at all in solution.

(b) Do the same calculation, assuming that the van't Hoff factor for Na_3PO_4 reflects 100% dissociation into its ions.

(c) The 1.00 *m* solution boils at 100.183 °C at 1 atm. Calculate the van't Hoff factor for the solute in this solution.

***13.91** A 2.50 g sample of aluminum chloride and sodium sulfate has a freezing point depression of 2.65 °C. Assuming complete dissociation of all ions, what are the molarities of aluminum chloride and sodium sulfate?

| Multi-Concept Problems

***13.92** A sample containing only iron(II) nitrate and potassium chloride is dissolved in water and the boiling point of the mixture is 104.6 °C. That same solution is reacted with 36.3 mL of 0.220 *M* $K_2Cr_2O_7$ solution that completely converts the iron(II) to iron(III). What are the molarities of iron(II) nitrate and potassium chloride in the original solution? The density of the mixture is 1.032 g/mL and we assume all soluble species are completely dissociated.

***13.93** A 25.00 mL sample of a 0.200 *M* solution of barium nitrate is mixed with 14.00 mL of a 0.250 *M* solution of potassium sulfate. Assuming that all ionic species are completely dissociated, what is the osmotic pressure of the mixture in torr?

***13.94** A compound is found to have a molecular formula of C_2H_6O. Write all of the possible structural formulas for this compound. With a relevant explanation, determine whether each of your structures will

(a) be expected to be a solid, liquid or gas at 25 °C.

(b) be soluble in water or pentane.

(c) form hydrogen bonds.

(d) be a strong electrolyte, a weak electrolyte, or a nonelectrolyte.

***13.95** How many mL of 0.223 *M* $K_2Cr_2O_7$ are needed to completely oxidize 155 mL of 0.650 *M* tin(II) chloride to tin(IV)? When the reaction is complete, what will the osmotic pressure be, in torr?

***13.96** An experiment calls for the use of the dichromate ion, $Cr_2O_7^{2-}$, in sulfuric acid as an oxidizing agent for isopropyl alcohol, C_3H_8O. The chief product is acetone, C_3H_6O, which forms according to the following equation.

$$3C_3H_8O + Na_2Cr_2O_7 + 4H_2SO_4 \longrightarrow 3C_3H_6O + Cr_2(SO_4)_3 + Na_2SO_4 + 7H_2O$$

(a) The oxidizing agent is available only as sodium dichromate dihydrate. What is the minimum number of grams of sodium dichromate dihydrate needed to oxidize 21.4 g of isopropyl alcohol according to the balanced equation?

(b) The amount of acetone actually isolated was 12.4 g. Calculate the percentage yield of acetone.

(c) The reaction produces a volatile by-product. When a sample of it with a mass of 8.654 mg was burned in oxygen, it was converted into 22.368 mg of carbon dioxide and 10.655 mg of water, the sole products. (Assume that any unaccounted for element is oxygen.) Calculate the percentage composition of the by-product and determine its empirical formula.

(d) A solution prepared by dissolving 1.338 g of the by-product in 115.0 g of benzene had a freezing point of 4.87 °C. Calculate the molecular mass of the by-product and write its molecular formula.

Exercises in Critical Thinking

13.97 A certain organic substance is soluble in solvent *A* but it is insoluble in solvent *B*. If solvents *A* and *B* are miscible, will the organic compound be soluble in a mixture of *A* and *B*? What additional information is needed to answer this question?

13.98 The situation described in Problem 13.97 is actually quite common. How might it be used to purify the organic compound?

13.99 Compile and review all of the methods discussed for the determination of molecular masses. Assess which methods are the most reliable, most sensitive, and which are the most convenient to use.

13.100 Having had some laboratory experience by now, evaluate whether preparation of a 0.25 *molar* solution is easier or more difficult than preparing a 0.25 *molal* solution. What experiments require the use of *molal* concentrations?

13.101 This chapter focused on the physical description of osmosis and its use in determining molar masses. What other uses are there for osmosis?

13.102 Using the principles developed in this chapter, explain why all solids will eventually result in a saturated solution if enough solid is added to the solvent.

13.103 It is observed that when 10.0 g of a substance is dissolved in a specific solvent, 2.43 kJ of heat are produced. When the next 10.0 gram sample is added and dissolved, 2.16 kJ of heat are produced. Use the concepts of state functions and the principles in Section 13.2 to explain this observation.

13.104 What would be the result if molarity rather than molality was used in freezing point depression (and boiling point elevation) experiments? What changes would be needed to make the molarity system work?

Chapters 11–13

Bringing It Together

Again we pause to provide you with an opportunity to see how well you have grasped concepts, how familiar you are with important terms, and how able you are at working chemistry problems. Keep in mind that many of the problems require tools developed in more than one chapter, including tools from Chapters 1–10. As you proceed, we encourage you to follow the approach taken by the worked examples you've studied.

1. A 9.46 g sample of neon at 25.0 °C and a pressure of 748 torr is kept at 25.0 °C as it is allowed to expand to a final volume of 25.4 L. What is the final pressure?

2. An 8.95 L sample of nitrogen at 25.0 °C and 1.00 atm is compressed to a volume of 0.895 L and a pressure of 5.56 atm. What must its final temperature be?

3. What is the chemical symbol of a gaseous element if 6.45 g of it occupies 1.92 L at 745 torr and 25.0 °C?

4. What is the molar mass of a gaseous element if at room temperature it effuses through a pinhole 2.16 times as rapidly as xenon? Which element is it?

5. If a gas in a cylinder pushes back a piston against a constant opposing pressure of 3.0×10^5 pascals and undergoes a volume change of 0.50 m^3, how much work will the gas do, expressed in joules?

6. A sample of oxygen-enriched air with a volume of 12.5 L at 25.0 °C and 1.00 atm consists of 45.0% (v/v) oxygen and 55.0% (v/v) nitrogen. What are the partial pressures of oxygen and nitrogen (in torr) in this sample after it has been warmed to a temperature of 37.0 °C and its volume is changed to 10.7 L?

7. How many milliliters of dry CO_2, measured at STP, could be evolved in the reaction between 20.0 mL of 0.100 *M* $NaHCO_3$ and 30.0 mL of 0.0800 *M* HCl?

8. How many milliliters of Cl_2 gas, measured at 25 °C and 740 torr, are needed to react with 10.0 mL of 0.10 *M* NaI if the I^- is oxidized to IO_3^- and Cl_2 is reduced to Cl^-?

9. Potassium hypobromite converts ammonia to nitrogen by a reaction in which hypobromite ion is reduced to bromide ion. To prepare 475 mL of dry N_2, when measured at 24.0 °C and 738 torr, what is the minimum number of grams of potassium hypobromite required?

10. Hydrogen peroxide, H_2O_2, is decomposed by potassium permanganate according to the following reaction.

$$5H_2O_2 + 2KMnO_4 + 3H_2SO_4 \longrightarrow 5O_2 + 2MnSO_4 + K_2SO_4 + 8H_2O$$

What is the minimum number of milliliters of 0.125 *M* $KMnO_4$ required to prepare 375 mL of dry O_2 when the gas volume is measured at 22.0 °C and 738 torr?

11. A sample of 248 mL of wet nitrogen gas was collected over water at a total gas pressure of 736 torr and a temperature of 21.0 °C. (The vapor pressure of water at 21.0 °C is 18.7 torr.) The nitrogen was produced by the reaction of sulfamic acid, HNH_2SO_3, with 425 mL of a solution of sodium nitrite according to the following equation.

$$NaNO_2 + HNH_2SO_3 \longrightarrow N_2 + NaHSO_4 + H_2O$$

Calculate what must have been the molar concentration of the sodium nitrite.

12. One way to make chlorine gas is to let manganese(IV) oxide react with hydrochloric acid in which the manganese is reduced to Mn^{2+}. What is the minimum volume (in mL) of 6.44 *M* HCl needed to prepare 525 mL of dry chlorine when the gas is obtained at 24.0 °C and 742 torr?

13. Hexanitroethane, $C_2(NO_2)_6$, decomposes explosively if heated above 140 °C. It is estimated that ΔH_f° for $C_2(NO_2)_6(s)$ is $+96$ kJ mol^{-1}. (a) Calculate ΔH° for the decomposition of $C_2(NO_2)_6$ according to the equation

$$C_2(NO_2)_6(s) \longrightarrow 2NO_2(g) + 4NO(g) + 2CO_2(g)$$

(b) Suppose 1.26 g of $C_2(NO_2)_6(s)$ is placed in a 200.0 cm^3 vessel where it is detonated. The heat capacities, C_v, at 25 °C for the gases formed are as follows: CO_2, 28.5 J mol^{-1} K^{-1}; NO, 21.5 J mol^{-1} K^{-1}; NO_2, 29.5 J mol^{-1} K^{-1}. Assuming the heat capacities don't change and all the heat liberated in the reaction remains in the container, what will be the pressure of the mixture of gases after detonation?

14. Consider the molecule $POCl_3$, in which phosphorus is the central atom and is bonded to an oxygen atom and three chlorine atoms.

(a) Draw the Lewis structure of $POCl_3$ and predict its geometry.

(b) Is the molecule polar or nonpolar? Explain.

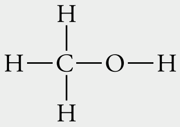
(c) What kinds of attractive forces would be present between $POCl_3$ molecules in the liquid?

15. What kinds of attractive forces, including chemical bonds, would be present between the particles in

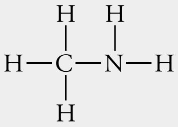
(a) $H_2O(l)$
(b) $CCl_4(l)$
(c) $CH_3OH(l)$
(d) $BrCl(l)$
(e) $NaCl(s)$
(f) $Na_2SO_4(s)$

16. Trimethylamine $(CH_3)_3N$, is a substance responsible in part for the smell of fish. It has a boiling point of 3.5 °C and a molecular weight of 59.1. Dimethylamine, $(CH_3)_2NH$, has a similar odor and boils at a slightly higher temperature, 7 °C, even though it has a somewhat lower molecular mass (45.1). How can this be explained in terms of the kinds of attractive forces between their molecules?

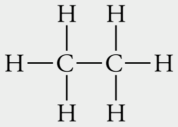
17. Methanol, CH_3OH, commonly known as wood alcohol, has a boiling point of 64.7 °C. Methylamine, a fishy-smelling chemical found in herring brine, has a boiling point of −6.3 °C. Ethane, a hydrocarbon present in petroleum, has a boiling point of −88 °C.



methanol
b.p. 64.7 °C



methylamine
b.p. −6.3 °C



ethane
b.p. −88 °C

Each has nearly the same molecular mass. Account for the large differences in their boiling points in terms of the attractive forces between their molecules.

18. Based on what you've learned in these chapters, explain:

(a) Why a breeze cools you when you're perspiring.

(b) Why droplets of water form on the outside of a glass of cold soda on a warm, humid day.

(c) Why you feel more uncomfortable on a warm, humid day than on a warm, dry day.

(d) The origin of the energy in a violent thunderstorm.

(e) Why clouds form as warm, moist air flows over a mountain range.

19. Aluminum has a density of 2.70 g cm^{-3} and crystallizes in a face-centered cubic lattice. Use these and other data to calculate the atomic radius of an aluminum atom.

20. What is the difference between the closest-packed structures identified as ccp and hcp? In each of these structures, how many atoms are in contact with any given atom?

21. Tin tetraiodide [tin(IV) iodide] has the formula SnI_4. It forms soft, yellow to reddish crystals that melt at about 143 °C. What kind of solid does SnI_4 form? What kind of bonding occurs in SnI_4?

22. Sketch the phase diagram for a substance that has a triple point at 25 °C and 100 torr, a normal boiling point of 150 °C, and a melting point at 1 atm of 27 °C. Is the solid more dense or less dense than the liquid? Where on the curve would the critical temperature and critical pressure be? What phase would exist at 30 °C and 10.0 torr?

23. How many grams of 4.00% (w/w) solution of KOH in water are needed to neutralize completely the acid in 10.0 mL 0.256 M H_2SO_4?

24. Calculate the molar concentration of 15.00% (w/w) Na_2CO_3 solution at 20.0 °C given that its density is 1.160 g/mL.

25. The solubility of pure oxygen in water at 20.0 °C and 760 torr is 4.30×10^{-2} g O_2 per liter of H_2O. When air is in contact with water and the air pressure is 585 torr at 20 °C, how many grams of oxygen from the air dissolve in 1.00 L of water? The average concentration of oxygen in the air is 21.1% (v/v).

26. If the element gallium, Ga, is added to germanium, which kind of semiconductor (*n* or *p*) will result? Explain your answer.

27. Compound XY is an ionic compound that dissociates as it dissolves in water. The lattice energy of XY is −600 kJ/mol. The hydration energy of its ions is −610 kJ/mol.

(a) Write the thermochemical equations for the two steps in the formation of a solution of XY in water.

(b) Write the sum of these two equations in the form of a thermochemical equation, showing the net ΔH.

(c) Draw an enthalpy diagram for the formation of this solution.

28. At 20 °C a 40.00% (v/v) solution of ethanol in water has a density of 0.9369 g/mL. (Such a solution could be prepared, for example, by mixing 40.00 mL of ethanol with enough water to give 100.00 mL of solution.) The density of pure ethanol at this temperature is 0.7907 g/mL and that of water is 0.9982 g/mL.

(a) Calculate the molar concentration and the molal concentration of ethanol in this solution.

(b) Calculate the concentration of ethanol in this solution in mole fractions and mole percents.

(c) The vapor pressure of ethanol at 20 °C is 41.0 torr and of water is 17.5 torr. If the 40.00% (v/v) solution were ideal, what would be the vapor pressure of each component over the solution?

29. Estimate the boiling point of 1.0 molal $Al(NO_3)_3$, assuming that it dissociates entirely into Al^{3+} and NO_3^- ions in solution.

30. Squalene is an oil found chiefly in shark liver oil but is also present in low concentrations in olive oil, wheat germ oil, and yeast. A qualitative analysis disclosed that its molecules consist entirely of carbon and hydrogen. When a sample of squalene with a mass of 0.5680 g was burned in pure oxygen, there was obtained 1.8260 g of carbon dioxide and 0.6230 g of water.

(a) Calculate the empirical formula of squalene.

(b) When 0.1268 g of squalene was dissolved in 10.50 g of molten camphor, the freezing point of this solution was 177.3 °C. (The melting point of pure camphor is 178.4 °C, and its molal freezing point depression constant is 37.5 °C kg $camphor^{-1}$.) Calculate the formula mass of squalene and determine its molecular formula.

14.1 | Factors that Affect Reaction Rates

14.2 | Measuring Reaction Rates

14.3 | Rate Laws

14.4 | Integrated Rate Laws

14.5 | Molecular Basis of Collision Theory

14.6 | Molecular Basis of Transition State Theory

14.7 | Activation Energies

14.8 | Mechanisms of Reactions

14.9 | Catalysts

Why can't butterflies fly when it is cold? When the temperature drops, insects move slower because the chemical reactions that allow their muscles to move occur at slower rates. As we will see in this chapter, the rates of reactions depend on the temperatures at which they occur. The butterfly was too cold, so the reactions needed to contract the muscles were too slow to allow the butterfly to fly away. Courtesy of James Brady

This Chapter in Context

Chemical reactions run at many different speeds. Some, such as the rusting of iron or the breakdown of plastics in the environment, take place very slowly. Others, like the combustion of gasoline or the explosion of gunpowder, occur very quickly. **Chemical kinetics** is the study of the speeds (or *rates*) of chemical reactions. On a practical level, chemical kinetics is concerned with factors that affect the speeds of reactions and how reaction speeds can be controlled. This is essential in industry, where synthetic reactions must take place at controlled speeds. If a reaction takes weeks or months to occur, it may not be economically feasible; if it occurs too quickly or uncontrollably, it may result in an explosion. For the consumer, studies on rates of decomposition allow a manufacturer to reliably determine the shelf life, or expiration date, of a product or drug. At a more fundamental level, a study of the speed of a reaction often gives clues that lead to an understanding about *how*, at the molecular level, reactants change into products. Understanding the reaction at this level of detail often allows more precise control of the reaction's speed, and suggests ways to modify the reaction to produce new types of products, or to improve the reaction's yield by preventing undesirable side reactions from occurring.

14.1 | Factors that Affect Reaction Rates

The **rate of reaction** for a given chemical change is the speed with which the reactants disappear and the products form. When a reaction is fast, more product is formed in a given period of time than in a slow reaction. Reaction rate is measured by the amount of products produced or reactants consumed per unit time. Usually this is done by monitoring the concentrations of the reactants or products over time, as the reaction proceeds (see Figure 14.1).

Before we take up the quantitative aspects of reaction rates, let's look qualitatively at factors that can make a reaction run faster or slower. There are five principal factors that influence reaction rates.

1. Chemical nature of the reactants themselves
2. Ability of the reactants to come in contact with each other
3. Concentrations of the reactants
4. Temperature
5. Availability of rate-accelerating agents called *catalysts*

TOOLS

Factors that affect reaction rates

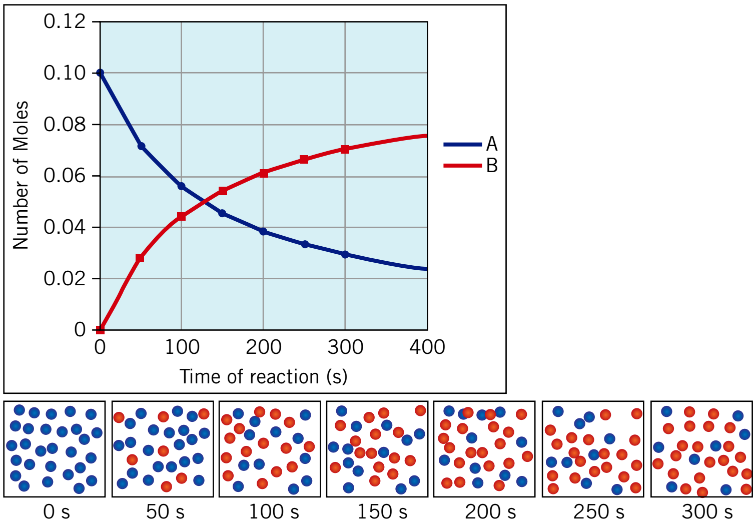

Figure 14.1 | **Reaction rates are measured by monitoring concentration changes over time.** For the reaction, $A \longrightarrow B$, the number of A molecules (in blue) decreases with time as the number of B molecules (in red) increases. The steeper the concentration versus time curves are, the faster the rate of reaction is. The filmstrip represents the relative numbers of molecules of A and B at each time.

Chemical Nature of the Reactants

Bonds break and new bonds form during reactions. The most fundamental differences among reaction rates, therefore, lie in the reactants themselves, in the inherent tendencies for their atoms, molecules, or ions to undergo changes in chemical bonds or oxidation states. Some reactions are fast by nature and others are slow (Figure 14.2). For example, because sodium atoms lose electrons easily, a freshly exposed surface of metallic sodium tarnishes when exposed to air and moisture. Under identical conditions, potassium also reacts with air and moisture, but the reaction is much faster because potassium atoms lose electrons more easily than sodium atoms.

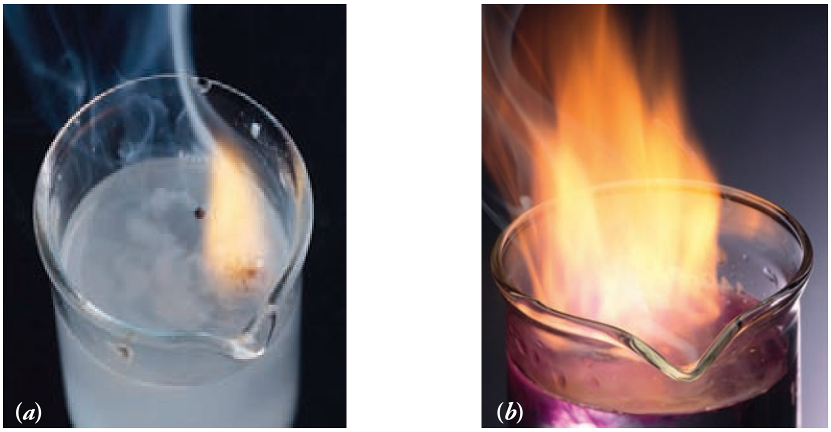

Figure 14.2 | **The chemical nature of reactants affects reaction rates.** (*a*) Sodium loses electrons easily, so it reacts quickly with water. (*b*) Potassium loses electrons even more easily than sodium, so its reaction with water is explosively fast. *(Fundamental Photographs)*

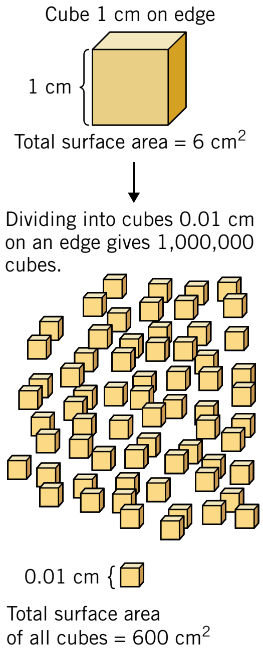
Ability of the Reactants to Meet

Most reactions involve two or more reactants whose particles (i.e., atoms, ions, or molecules) must collide with each other for the reaction to occur. This is why reactions are often carried out in liquid solutions or in the gas phase. In these states, the particles are able to intermingle at a molecular level and collide with each other easily.

Reactions in which all of the reactants are in the same phase are called **homogeneous reactions.** Examples include the neutralization of sodium hydroxide by hydrochloric acid when both are dissolved in water, and the explosive reaction in the gas phase of gasoline vapor with oxygen that can occur when the two are mixed in the right proportions in a gasoline engine. (An *explosion* is an extremely rapid reaction that generates hot expanding gases.)

When the reactants are present in different phases—for example, when one is a gas and the other is a liquid or a solid—the reaction is called a **heterogeneous reaction**. In a heterogeneous reaction, the reactants are able to meet only at the interface between the phases, so *the area of contact between the phases is a major factor in determining the rate of the reaction.* This area is controlled by the sizes of the particles of the reactants. By pulverizing a solid, the total surface area can be hugely increased (Figure 14.3). This maximizes contact between the atoms, ions, or molecules in the solid state with those in a different phase. As a result, in heterogeneous reactions, smaller particles tend to react faster than large ones.

Although heterogeneous reactions such as those just illustrated are important, they are very complex and difficult to analyze. In this chapter, therefore, we'll focus mostly on homogeneous systems.



Cube 1 cm on edge
1 cm
Total surface area = 6 cm^2
Dividing into cubes 0.01 cm on an edge gives 1,000,000 cubes.
0.01 cm
Total surface area of all cubes = 600 cm^2

Figure 14.3 | **Effect of crushing a solid.** When a single solid is subdivided into much smaller pieces, the total surface area on all of the pieces becomes very large.

Concentrations of the Reactants

The rates of both homogeneous and heterogeneous reactions are affected by the concentrations of the reactants. For example, wood burns relatively quickly in air but extremely rapidly in pure oxygen. It has been estimated that if air were 30% oxygen instead of 21%, it would be impossible to put out forest fires. Even red hot steel wool, which only sputters and glows in air, bursts into flame when thrust into pure oxygen (see Figure 14.4).

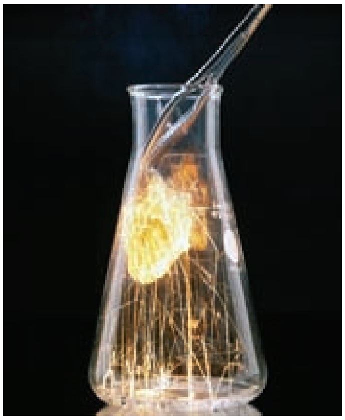


Figure 14.4 | **Effect of concentration on rate.** Using pure oxygen instead of air, steel wool, after being heated to redness in a flame, burns spectacularly. *(© 1993 Richard Megna/ Fundamental Photographs)*

Temperature of the System

Chemical reactions occur faster at higher temperatures than they do at lower temperatures. You may have noticed, for example, that insects move more slowly when the air is cool, as in the chapter-opening photograph of the butterfly. An insect is a cold-blooded creature, which means that its body temperature is determined by the temperature of its surroundings. As the air cools, insects cool, and so the rates of their metabolic reactions slow down, making the insects sluggish.

Presence of Catalysts

Catalysts are substances that increase the rates of chemical reactions without being used up. They affect every moment of our lives. In our bodies, substances called enzymes serve as catalysts for biochemical reactions. By making enzymes available or not, a cell is able to direct our body chemistry by controlling which chemical reactions can occur rapidly. Catalysts are used in the chemical industry to make gasoline, plastics, fertilizers, and other products that have become virtual necessities in our lives.

14.2 | Measuring Reaction Rates

The qualitative factors discussed in Section 14.1 can also be described quantitatively. To do this, we need to express reaction rates in mathematical terms. Let's start with the concept of **rate**, a change in quantity per unit time. This always implies a ratio in which a unit of time is in the denominator. Suppose, for example, that you have a job with a pay rate of ten dollars per hour. Because *per* can be translated as *divided by*, your rate of pay can be written as a fraction (abbreviating hour as hr):

$$\text{Rate of pay} = 10 \text{ dollars per hour} = \frac{10 \text{ dollars}}{1 \text{ hr}} = 10 \text{ dollars hr}^{-1}$$

Here we've expressed the fraction 1/hr as hr^{-1}.

When chemical reactions occur, the concentrations of reactants decrease as they are used up, while the concentrations of the products increase as they form. So, one way to describe a reaction's rate is to pick one substance in the reaction's equation and describe its change in concentration per unit of time. The result is the rate of the reaction *with respect to that substance.* Remembering that we always take "final minus initial," the rate of reaction with respect to substance X is given in Equation 14.1.

$$\begin{aligned}\text{Rate with respect to } X &= \frac{(\text{conc. of } X \text{ at time } t_f - \text{conc. of } X \text{ at time } t_i)}{(t_f - t_i)} \\ &= \frac{\Delta(\text{conc. of } X)}{\Delta t} \qquad \textbf{(14.1)}\end{aligned}$$

TOOLS

Rate with respect to one reactant or product

Molarity (mol/L) is normally the concentration unit, and the second (s) is the most often used unit of time. Therefore, the units for reaction rates are most frequently the following:

$$\frac{\text{mol/L}}{\text{s}}$$

The units for a reaction rate can also be expressed as **mol L⁻¹ s⁻¹**. By convention, reaction rate is reported as a positive value, whether the rate was measured as the concentration of the product increases or the concentration of the reactants decreases. For instance, if the concentration of one product of a reaction increases by 0.50 mol/L each second, the rate of its formation is 0.50 mol L^{-1} s^{-1}. Similarly, if the concentration of a reactant decreases by 0.20 mol/L per second, its rate with respect to the reactant is 0.20 mol L^{-1} s^{-1}.

Relative Rates and Reaction Stoichiometry

When we know the value of a reaction rate with respect to one substance, the coefficients of the reaction's balanced chemical equation can be used to find the rates with respect to the other substances. For example, in the combustion of propane,

$$C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(g)$$

five moles of O_2 *must* be consumed per unit of time for each mole of C_3H_8 used in the same time. In this reaction, therefore, oxygen *must* react five times faster than propane in units of mol L^{-1} s^{-1}. Similarly, CO_2 forms three times faster than C_3H_8 reacts and H_2O forms four times faster. The magnitudes of the rates relative to each other are thus in the same relationship as the coefficients in the balanced chemical equation.

Example 14.1
Relationships of Rates within a Reaction

Butane, the fuel in cigarette lighters, burns in oxygen to give carbon dioxide and water. If, in a certain experiment, the butane concentration is decreasing at a rate of 0.20 mol L^{-1} s^{-1}, what is the rate at which the oxygen concentration is decreasing, and what are the rates at which the product concentrations are increasing?

- **Analysis:** As always, we need a balanced chemical equation. Butane, C_4H_{10}, burns in oxygen to give CO_2 and H_2O according to the following balanced chemical equation:

$$2C_4H_{10}(g) + 13O_2(g) \longrightarrow 8CO_2(g) + 10H_2O(g)$$

We now need to relate the rate with respect to oxygen and the products to the given rate with respect to butane. The magnitudes of the rates relative to each other are in the same relationship as the coefficients in the balanced chemical equation.

- **Assembling the Tools:** The chemical equation is the tool that links the stoichiometric amounts of these substances to the amount of butane. The other tool will be Equation 14.1 for calculating the rate of a reaction.

- **Solution:** For oxygen,

$$\frac{0.20\ \cancel{\text{mol C}_4\text{H}_{10}}}{\text{L s}} \times \frac{13\ \text{mol O}_2}{2\ \cancel{\text{mol C}_4\text{H}_{10}}} = \frac{1.3\ \text{mol O}_2}{\text{L s}}$$

Oxygen is reacting at a rate of 1.3 mol L^{-1} s^{-1}. For CO_2 and H_2O, we have similar calculations:

$$\frac{0.20\ \cancel{\text{mol C}_4\text{H}_{10}}}{\text{L s}} \times \frac{8\ \text{mol CO}_2}{2\ \cancel{\text{mol C}_4\text{H}_{10}}} = \frac{0.80\ \text{mol CO}_2}{\text{L s}}$$

$$\frac{0.20\ \cancel{\text{mol C}_4\text{H}_{10}}}{\text{L s}} \times \frac{10\ \text{mol H}_2\text{O}}{2\ \cancel{\text{mol C}_4\text{H}_{10}}} = \frac{1.0\ \text{mol H}_2\text{O}}{\text{L s}}$$

Therefore,

$$\text{Rate with respect to the formation of CO}_2 = 0.80\ \text{mol L}^{-1}\ \text{s}^{-1}$$
$$\text{Rate with respect to the formation of H}_2\text{O} = 1.0\ \text{mol L}^{-1}\ \text{s}^{-1}$$

■ **Are the Answers Reasonable?** If what we've calculated is correct, then the ratio of the numerical values of the last two rates—namely, 0.80 to 1.0—should be the same as the ratio of the corresponding coefficients in the chemical equation—namely, 8 to 10 (the same ratio as 0.8 to 1.0).

Practice Exercises

14.1 | The iodate ion reacts with sulfite ions in the reaction

$$IO_3^- + 3SO_3^{2-} \longrightarrow I^- + 3SO_4^{2-}$$

At what rate are the iodide and sulfate ions being produced if the sulfite ion is disappearing at a rate of 2.4×10^{-4} mol L^{-1} s^{-1}? (*Hint:* Pay attention to the stoichiometry.)

14.2 | Hydrogen sulfide burns in oxygen to form sulfur dioxide and water. If sulfur dioxide is being formed at a rate of 0.30 mol L^{-1} s^{-1}, what are the rates of disappearance of hydrogen sulfide and oxygen?

Because the rates of reaction of reactants and products are all related, it doesn't matter which species we pick to follow concentration changes over time. For example, to study the decomposition of hydrogen iodide, HI, into H_2 and I_2,

$$2HI(g) \longrightarrow H_2(g) + I_2(g)$$

it is easiest to monitor the I_2 concentration because it is the only colored substance in the reaction. As the reaction proceeds, purple iodine vapor forms, and there are instruments that allow us to relate the intensity of the color to the iodine concentration. Then, once we know the rate of formation of iodine, we also know the rate of formation of hydrogen. It is the same because the coefficients of H_2 and I_2 are the same in the balanced chemical equation. And the rate of disappearance of HI, which has a coefficient of 2 in the equation, is twice as fast as the rate of formation of I_2.

Because reactants and products are consumed and formed at different rates, we would like to find a way to express the speed of a reaction in a way that is independent of which reactant or product is monitored. To accomplish this, we divide the relative rate of reaction with respect to a given substance by the coefficient of the substance in the balanced chemical equation. The result is a quantity we will call the **rate of reaction**. Consider, for example, the combustion of propane discussed previously:

$$C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(g)$$

The rate at which O_2 is changing can be expressed as

$$\text{rate } O_2 = -\frac{\Delta[O_2]}{\Delta t}$$

where we have used square brackets around the chemical formula to denote molar concentration. Because the O_2 concentration is decreasing, we need a negative sign to make the rate a positive quantity. The *rate of reaction* would then be calculated by dividing the relative rate for O_2 by its coefficient, 5.

■ Square brackets around chemical formulas is the standard way to denote molar concentration. You will see this frequently in the chapters ahead.

$$\text{Rate} = -\frac{1}{5}\frac{\Delta[O_2]}{\Delta t}$$

Each of the other relative rates is treated in the same way to give the *same* value for the rate of reaction:

$$\text{Rate} = -\frac{1}{1}\frac{\Delta[C_3O_8]}{\Delta t} = -\frac{1}{5}\frac{\Delta[O_2]}{\Delta t} = \frac{1}{3}\frac{\Delta[CO_2]}{\Delta t} = \frac{1}{4}\frac{\Delta[H_2O]}{\Delta t}$$

For a generalized reaction

$$aA + bB \longrightarrow cC + dD$$

the rate is given by Equation 14.2,

Rate of a reaction

$$\text{rate} = -\frac{1}{a}\frac{\Delta[A]}{\Delta t} = -\frac{1}{b}\frac{\Delta[B]}{\Delta t} = \frac{1}{c}\frac{\Delta[C]}{\Delta t} = \frac{1}{d}\frac{\Delta[D]}{\Delta t} \tag{14.2}$$

Example 14.2
Rates of a Reaction

In Example 14.1, butane burned in oxygen to give carbon dioxide and water at a rate of 0.20 mol L^{-1} s^{-1} with respect to butane. What is the rate for the reaction independent of any of the reactants or products?

Analysis: We are given the rate of the reaction with respect to butane. We can use the balanced chemical equation from Example 14.1 and the stoichiometric coefficients,

$$2C_4H_{10}(g) + 13O_2(g) \longrightarrow 8CO_2(g) + 10H_2O(g)$$

We will relate the rate of the reaction with respect to butane to the rate of the reaction independent of the reactants or products.

Assembling the Tools: Just as in Example 14.1, we will use the balanced chemical equation as a tool because it gives the stoichiometric ratio of the reactants and products. We will then use Equation 14.2 to calculate the rate of the reaction.

Solution: We are given the relative rate of the reaction of butane as 0.20 mol L^{-1} s^{-1}. We also have the balanced chemical equation for the combustion of butane with the coefficient of 2 for butane.

$$\text{rate}_{\text{with respect to butane}} = -\frac{\Delta[C_4H_{10}]}{\Delta t} = -\frac{0.20 \text{ mol}}{\text{L s}}$$

$$\text{rate}_{\text{reaction}} = -\left[\frac{1}{2} \times \left(\frac{-0.20 \text{ mol}}{\text{L s}}\right)\right]$$

$$= 0.1 \; \frac{\text{mol}}{\text{L s}}$$

Are the Answers Reasonable? Since the coefficient for butane is greater than one, the rate for the reaction should be less than the rate with respect to butane. Our value, 0.1 mol L^{-1} s^{-1}, is half the value of 0.2 mol L^{-1} s^{-1}, which makes sense.

Reaction Rates versus Time

A reaction rate is rarely constant throughout the reaction but commonly changes as the reactants are used up. This is because the rate usually depends on the concentrations of the reactants, and these change as the reaction proceeds. For example, Table 14.1 lists data for the decomposition of hydrogen iodide at a temperature of 508 °C. The data, which show the changes in molar HI concentration over time, are plotted in Figure 14.5. Notice that the molar HI concentration decreases fairly rapidly during the first 50 seconds of the reaction, which means that the initial rate is relatively fast. However, later, in the interval between 300 s and 350 s, the concentration changes by only a small amount, so the rate has slowed considerably. Thus, the steepness of the curve at any moment reflects the rate of the reaction; the steeper the curve, the higher is the rate.

Table 14.1 Data, at 508 °C, for the Reaction

$$2HI(g) \longrightarrow H_2(g) + I_2(g)$$

Concentration of HI (mol/L)	Time (s) (measured to 1 second)
0.100	0
0.0716	50
0.0558	100
0.0457	150
0.0387	200
0.0336	250
0.0296	300
0.0265	350

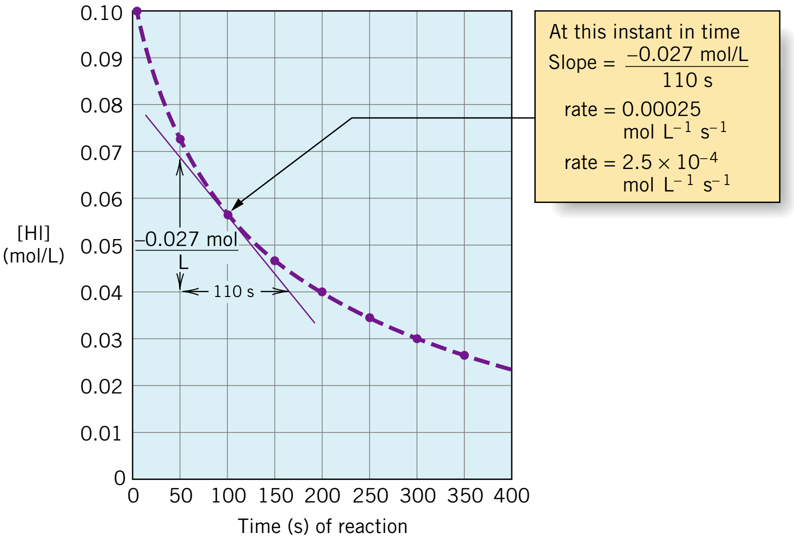

Figure 14.5 | **Effect of time on concentration.** The data for this plot of the change in the concentration of HI with time for the reaction,

$$2HI(g) \longrightarrow H_2(g) + I_2(g)$$

at 508 °C are taken from Table 14.1. The slope is negative because we're measuring the *disappearance* of HI, but when its value is used as a rate of reaction, we express the rate as positive.

The rate at which the HI is being consumed at any particular moment is called the **instantaneous rate**. When we use the term "reaction rate" we mean the instantaneous rate, unless we state otherwise. The instantaneous rate can be determined from the slope of the curve measured at the time we have chosen. The slope, which can be read off the graph, is the ratio (expressed positively) of the change in concentration to the change in time. In Figure 14.5, for example, the relative rate of the decomposition of hydrogen iodide is determined for a time 100 seconds from the start of the reaction. After the tangent to the curve is drawn, we measure a concentration change (a decrease of 0.027 mol/L) and the time change (110 s) from the graph of the tangent line. Because the rate is based on a *decreasing* concentration, we use a minus sign for the *equation* that describes this rate so that the rate itself will be a positive quantity.

■ The average rate is the slope of a line connecting two points on a concentration versus time graph. The instantaneous rate is the slope of a tangent line at a single point. The average and instantaneous rates are quite different from each other.

$$\text{Rate}_{\text{with respect to HI}} = -\left\{\frac{[\text{HI}]_{\text{final}} - [\text{HI}]_{\text{initial}}}{t_{\text{final}} - t_{\text{initial}}}\right\} = -\left\{\frac{-0.027\ \text{mol/L}}{110\ \text{s}}\right\}$$

$$\text{Rate}_{\text{with respect to HI}} = 2.5 \times 10^{-4}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

Thus, at this moment in the reaction, the rate with respect to HI is 2.5×10^{-4} mol L^{-1} s^{-1}. In Example 14.3, we'll use this technique to obtain the *initial instantaneous rate* of the reaction—that is, the instantaneous rate of reaction at time zero.

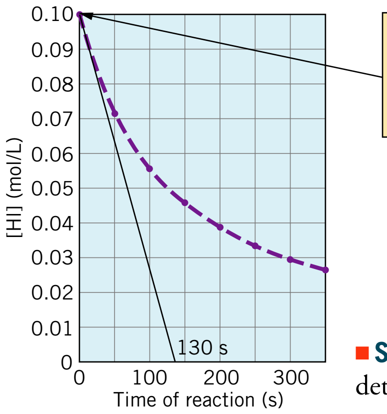
Example 14.3
Estimating the Initial Rate of a Reaction

Use the experimental data shown in Figure 14.5 for the reaction

$$2HI(g) \longrightarrow H_2(g) + I_2(g)$$

to determine the initial rate of reaction at 508 °C.

■ **Analysis:** The problem asks us to determine the initial rate, which is the instantaneous rate of reaction at time zero. However, we have to be careful here to distinguish between the *rate with respect to HI* and the quantity called the *rate of reaction*, which is the rate independent of the coefficients in the balanced chemical equation. Using the slope of the tangent line at $t = 0$ will allow us to determine the instantaneous rate of reaction *with respect to HI*. To determine the *rate of reaction*, we then have to divide the rate with respect to HI by the coefficient of HI in the balanced equation.



At time zero, slope of the tangent line = –(0.10 mol/L^{-1}) / 130 s
rate = 7.7 x 10^{-4} mol L^{-1} s^{-1}

Assembling the Tools: We will find the initial rate of reaction with respect to HI by determining the slope of the tangent line at time zero of the curve showing the HI concentration as a function of time in Figure 14.5. Remember that the slope of a straight line can be calculated from the coordinates of any two points (x_1, y_1) and (x_2, y_2) using the following equation:

$$\text{slope} = \frac{y_2 - y_1}{x_2 - x_1}$$

Solution: We can draw the line as shown in the graph in the margin. To more precisely determine the slope of the tangent line, we should choose two points that are as far apart as possible. The point on the curve (0 s, 0.10 mol/L) and the intersection of the tangent line with the time axis (130 s, 0 mol/L) are widely separated:

$$\text{slope} = \frac{0.10\ \text{mol/L} - 0.00\ \text{mol/L}}{0\ \text{s} - 130\ \text{s}} = -7.7 \times 10^{-4}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

The slope is negative because the concentration of HI is decreasing as time increases. Rates are positive quantities, so we can report the initial rate of reaction with respect to HI as 7.7×10^{-4} mol L^{-1} s^{-1}.

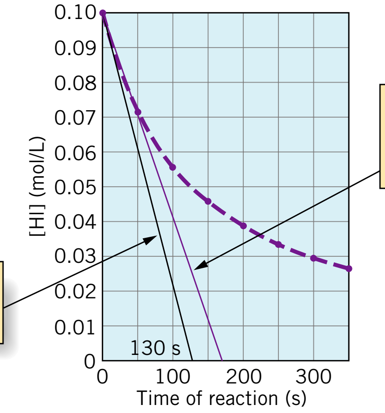
The initial rate of reaction (which is what we're asked to determine) is the rate with respect to HI divided by the coefficient of HI in the balanced equation:

$$\text{Rate of reaction} = \frac{7.7 \times 10^{-4}\ \text{mol L}^{-1}\ \text{s}^{-1}}{2} = 3.9 \times 10^{-4}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

Is the Answer Reasonable? The instantaneous rate for HI at time zero ought to be slightly larger than the *average rate* with respect to HI between zero and 50 seconds. We can compute the average rate directly from data in Table 14.1 by selecting a pair of concentrations of HI at two different times.

$$\text{slope} = \frac{0.0716\ \text{mol/L} - 0.100\ \text{mol/L}}{50\ \text{s} - 0\ \text{s}} = -5.7 \times 10^{-4}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

Thus, the average rate from 0 to 50 s is 5.7×10^{-4} mol L^{-1} s^{-1}. As expected, this is slightly less than 7.7×10^{-4} mol L^{-1} s^{-1} the instantaneous rate with respect to HI at time zero.



The slope of a line tangent to the curve at 0 s gives the **instantaneous rate** at time 0 s.

The slope of a line joining points at 0 s and 50 s gives the **average rate** over the first 50 s interval.

Practice Exercises

14.3 | Use the graph in Figure 14.5 to estimate the rate of reaction with respect to HI at 2.00 minutes after the start of the reaction. (*Hint:* On the graph, the time is given in seconds.)

14.4 | Use the graph in Figure 14.5 to estimate the rate of reaction with respect to HI at 250 seconds after the start of the reaction.

14.3 | Rate Laws

Thus far we have focused on a rate with respect to *one* component of a reaction. This rate was the experimental rate of a process for that particular reaction. We want to broaden our focus to consider a rate expression that includes all reactants, and have an expression that can give us the rate for any set of concentrations.

Rate Laws from Reaction Rates and Concentrations

The rate of a homogeneous reaction at any instant is proportional to the product of the molar concentrations of the reactants, each molarity raised to some power or exponent that has to be found experimentally. Let's consider a chemical reaction with an equation of the following form:

$$A + B \longrightarrow \text{products}$$

Its rate of reaction can be expressed as follows:

$$\text{rate} \propto [A]^m [B]^n \qquad \textbf{(14.3)}$$

where the values of the exponents n and m are found by experiment.

The proportionality symbol, $\propto$, in Equation 14.3 can be replaced by an equals sign if we introduce a proportionality constant, $\boldsymbol{k}$, which is called the **rate constant** for the reaction. This gives Equation 14.4:

$$\text{rate} = k\,[A]^m [B]^n \qquad \textbf{(14.4)}$$

TOOLS

Rate law of a reaction

Equation 14.4 is called the **rate law** for the reaction of A with B. Once we have found values for k, n, and m, the rate law allows us to calculate the rate of the reaction at any set of known values of concentrations. Consider, for example, the following reaction.

■ The value of k depends on the particular reaction being studied, as well as the temperature at which the reaction occurs.

$$H_2SeO_3 + 6I^- + 4H^+ \longrightarrow Se + 2I_3^- + 3H_2O$$

Its rate law is of the form

$$\text{rate} = k\,[H_2SeO_3]^x [I^-]^y [H^+]^z$$

The exponents have been found experimentally to be the following for the initial rate of this reaction (i.e., the rate when the reactants are first combined).

$$x = 1, \quad y = 3, \quad \text{and} \quad z = 2$$

At 0 °C, k equals $5.0 \times 10^5\ \text{L}^5\ \text{mol}^{-5}\ \text{s}^{-1}$. (We have to specify the temperature because k varies with T.) Substituting the exponents and the value of k into the rate law equation gives the rate law for the reaction:

■ The units of the rate constant are such that the calculated rate will have the units mol L^{-1} s^{-1}.

$$\text{rate} = (5.0 \times 10^5\ \text{L}^5\ \text{mol}^{-5}\ \text{s}^{-1})\,[H_2SeO_3]\,[I^-]^3\,[H^+]^2 \qquad (\text{at } 0\ °\text{C})$$

We can calculate the initial rate of the reaction at 0 °C for any set of concentrations of H_2SeO_3, I^-, and H^+ using this rate law.

Example 14.4
Calculating Reaction Rate from the Rate Law

In the stratosphere, molecular oxygen (O_2) can be broken into two oxygen atoms by ultraviolet radiation from the sun. If one of these oxygen atoms has enough energy and strikes an ozone (O_3) molecule in the stratosphere, the ozone molecule is destroyed, and two oxygen molecules are created:

$$O(g) + O_3(g) \longrightarrow 2O_2(g)$$

This reaction is part of the natural cycle of ozone destruction and creation in the stratosphere. What is the rate of ozone destruction *for this reaction alone* at an altitude of 25 km, if the rate law for the reaction is

$$\text{rate} = 4.15 \times 10^{5}\ \text{L mol}^{-1}\ \text{s}^{-1}\ [\text{O}_3][\text{O}]$$

and the reactant concentrations at 25 km are the following: $[O_3] = 1.2 \times 10^{-8}\ M$ and $[O] = 1.7 \times 10^{-14}\ M$?

Analysis: We are given the rate law, so the answer to this question is merely a matter of substituting the given molar concentrations into this law.

Assembling the Tools: We will use the given rate law for the reaction along with the concentrations to calculate the rate of the reaction.

Solution: To see how the units work out, let's write all of the concentration values as well as the rate constant's units in fraction form.

$$\text{Rate} = \left(\frac{4.15 \times 10^{5}\ \cancel{\text{L}}}{\cancel{\text{mol}}\ \text{s}}\right) \times \left(\frac{1.2 \times 10^{-8}\ \cancel{\text{mol}}}{\cancel{\text{L}}}\right) \times \left(\frac{1.7 \times 10^{-14}\ \text{mol}}{\text{L}}\right)$$

Performing the arithmetic and canceling the units yields

$$\text{rate} = \frac{8.5 \times 10^{-17}\ \text{mol}}{\text{L s}} = 8.5 \times 10^{-17}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

Is the Answer Reasonable? There's no simple check. Multiplying the powers of ten for the rate constant and the concentrations together reassures us that the rate is of the correct order of magnitude, and we can see that at least the answer has the correct units for a reaction rate.

Practice Exercises

14.5 | The rate law for the reaction $2NO(g) + 2H_2(g) \longrightarrow N_2(g) + 2H_2O(g)$ is

$$\text{rate} = k[\text{NO}]^2[\text{H}_2]$$

If the rate of reaction is 7.86×10^{-3} mol $L^{-1}s^{-1}$ when the concentrations of NO and H_2 are both 2×10^{-6} mol L^{-1}, (a) what is the value of the rate constant and (b) what are the units for the rate constant? (*Hint:* Note the units of the reaction rate.)

14.6 | The rate law for the decomposition of HI to I_2 and H_2 is

$$\text{rate} = k\,[\text{HI}]^2$$

At 508 °C, the rate of the reaction of HI was found to be 2.5×10^{-4} mol L^{-1} s^{-1} when the HI concentration was 0.0558 M (see Figure 14.5). (a) What is the value of k? (b) What are the units of k?

Orders of Reaction

Although a rate law's exponents are generally unrelated to the chemical equation's coefficients, they sometimes are the same by coincidence, as is the case in the decomposition of hydrogen iodide:

$$2HI(g) \longrightarrow H_2(g) + I_2(g)$$

The rate law, as we've said, is

$$\text{rate} = k\,[\text{HI}]^2$$

The exponent of [HI] in the rate law—namely, 2—happens to match the coefficient of HI in the overall chemical equation, but *there is no way we could have predicted this match* *without experimental data.* Therefore, *never* simply assume the exponents and the coefficients are the same; it's a trap that many students fall into.

An exponent in a rate law is called the **order of the reaction**[1] with respect to the corresponding reactant. For instance, the decomposition of gaseous N_2O_5 into NO_2 and O_2,

$$2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g)$$

has the rate law

$$\text{rate} = k\,[N_2O_5]$$

■ Mathematicians designate equations by the exponent of the unknown, and call it the order of the equation.

■ When the exponent on a concentration term is equal to 1, it is usually omitted.

The exponent of $[N_2O_5]$ is 1, so the reaction rate is said to be *first order* with respect to N_2O_5. The rate law for the decomposition of HI has an exponent of 2 for the HI concentration, so its reaction rate is *second order* in HI. The rate law

$$\text{rate} = k[H_2SeO_3]\,[I^-]^3\,[H^+]^2$$

describes a reaction rate that is first order with respect to H_2SeO_3, third order with respect to I^-, and second order with respect to H^+.

The **overall order of a reaction** is the sum of the orders with respect to each reactant in the rate law. The decomposition of N_2O_5 is a first-order reaction. The overall order for the reaction involving H_2SeO_3 is $1 + 3 + 2 = 6$.

The exponents in a rate law are usually small whole numbers, but fractional and negative exponents are occasionally found. A negative exponent means that the concentration term really belongs in the denominator, which means that as the concentration of the species increases, the rate of reaction decreases.

There are even *zero-order* reactions. They have reaction rates that are independent of the concentration of any reactant. Zero-order reactions usually involve a small amount of a catalyst that is saturated with reactants. This is rather like the situation in a crowded supermarket with only a single checkout lane open. It doesn't matter how many people join the line; the line will move at the same rate no matter how many people are standing in it. An example of a zero-order chemical reaction is the elimination of ethyl alcohol in the body, by the liver. Regardless of the blood alcohol level, the rate of alcohol removal by the body is constant, because the number of available catalyst molecules present in the liver is constant. Another zero-order reaction is the decomposition of gaseous ammonia into H_2 and N_2 on a hot platinum surface. The rate at which ammonia decomposes is the same, regardless of its concentration in the gas.

The rate law for a zero-order reaction is simply

$$\text{rate} = k$$

where the rate constant k has units of mol L^{-1} s^{-1}. The rate constant depends on the amount, quality, and available surface area of the catalyst. For example, forcing the ammonia through hot platinum powder (with a high surface area) would cause it to decompose faster than simply passing it over a hot platinum surface.

In all of the rate laws, the rate constant, k, indicates how fast a reaction proceeds. If the value for k is large, the reaction proceeds rapidly, and if k is small, the reaction is slow. The units for k must be such that the rate calculated from the rate law has units of mol L^{-1} s^{-1}. A list of units for k, as it depends on the overall order of the reaction, is given in Table 14.2.

Table 14.2 The Units for k as It Depends on the Overall Order of the Reaction

Overall Order	Units for k
0	mol L^{-1} s^{-1}
1	s^{-1}
2	L mol^{-1} s^{-1}
3	L^2 mol^{-2} s^{-1}
4	L^3 mol^{-3} s^{-1}

---

[1] The reason for describing the *order* of a reaction is to take advantage of a great convenience—namely, the mathematics involved in the treatment of the data is the same for all reactions having the same order. We will not go into this very deeply, but you should be familiar with this terminology; it's often used to describe the effects of concentration on reaction rates.

Practice Exercises

14.7 | The reaction,

$$BrO_3^- + 3SO_3^{2-} \longrightarrow Br^- + 3SO_4^{2-}$$

has the rate law

$$\text{rate} = k\,[BrO_3^-]\,[SO_3^{2-}]$$

What is the order of the reaction with respect to each reactant? What is the overall order of the reaction? (*Hint:* Recall that a concentration with no exponent has, in effect, an exponent of 1.)

14.8 | A certain reaction has an experimental rate law that is found to be second order in Cl_2 and first order in NO. Write the rate law for this reaction.

14.9 | For the reaction of HCO_2H with bromine, the balanced chemical equation is

$$HCO_2H(aq) + Br_2(aq) \longrightarrow 2H^+(aq) + 2Br^-(aq) + CO_2(aq)$$

and the rate law for this reaction is

$$\text{Rate} = k[Br_2]$$

What is the order of the reaction with respect to bromine and with respect to HCO_2H? What is the overall order of the reaction?

Obtaining Rate Laws from Experimental Data

We've mentioned several times that the exponents in the rate law of an overall reaction must be determined experimentally. *This is the only way to know for sure what the exponents are.* To determine the exponents, we study how changes in concentration affect the rate of the reaction. For example, consider again the following hypothetical reaction:

$$A + B \longrightarrow \text{products}$$

Suppose, further, that the data in Table 14.3 have been obtained in a series of five experiments. The form of the rate law for the reaction will be

$$\text{rate} = k\,[A]^n\,[B]^m$$

The values of n and m can be determined by looking for patterns in the rate data given in the table. *One of the easiest ways to reveal patterns in data is to form ratios of results using different sets of conditions.* Because this technique is quite generally useful, let's look in some detail at how it is applied to the problem of finding the rate law exponents.

TOOLS

Determining the order of reactions

For experiments 1, 2, and 3 in Table 14.3, the concentration of B has been held constant at 0.10 M. Any change in the rate for these first three experiments must be due to the change

Table 14.3 Concentration Rate Data for the Hypothetical Reaction $A + B \longrightarrow$ Products

Experiment	Initial Concentrations		Initial Rate of Formation of Products (mol L^{-1} s^{-1})
	$[A]$ (mol L^{-1})	$[B]$ (mol L^{-1})	
1	0.10	0.10	0.20
2	0.20	0.10	0.40
3	0.30	0.10	0.60
4	0.30	0.20	2.40
5	0.30	0.30	5.40

in $[A]$. The rate law tells us that when the concentration of B is held constant, the rate must be proportional to $[A]^n$, so if we take the ratio of rate laws for experiments 2 and 1, we obtain

$$\frac{\text{rate}_2}{\text{rate}_1} = \frac{k\ [A]_2^{\,n}[B]_2^{\,m}}{k\ [A]_1^{\,n}[B]_1^{\,m}} = \frac{k}{k}\left(\frac{[A]_2}{[A]_1}\right)^n\left(\frac{[B]_2}{[B]_1}\right)^m$$

For experiments 1 and 2, the left side of this equation is

$$\frac{\text{rate}_2}{\text{rate}_1} = \frac{0.40\ \cancel{\text{mol L}^{-1}\ \text{s}^{-1}}}{0.20\ \cancel{\text{mol L}^{-1}\ \text{s}^{-1}}} = 2.0$$

and on the right side of the equation the identical concentrations of B and the rate constant k cancel to give

$$\left(\frac{[A]_2}{[A]_1}\right)^n = \left(\frac{0.20\ \cancel{\text{mol L}^{-1}}}{0.10\ \cancel{\text{mol L}^{-1}}}\right)^n = 2.0^n$$

Thus, doubling $[A]$ in going from experiment 1 to experiment 2 doubles the rate, and the relationship reduces to $2.0 = 2.0^n$. For each unique combination of experiments 1, 2, and 3, we have

$$\begin{aligned} 2.0 &= 2.0^n \qquad &&\text{(for experiments 2 and 1)} \\ 3.0 &= 3.0^n \qquad &&\text{(for experiments 3 and 1)} \\ 1.5 &= 1.5^n \qquad &&\text{(for experiments 3 and 2)} \end{aligned}$$

The only value of n that makes all of these equations true is $n = 1$. Therefore, the reaction must be first order with respect to A.

A similar method will give us the exponent on $[B]$. In the final three experiments, the concentration of B changes while the concentration of A is held constant. This time it is the concentration of B that affects the rate. Taking the ratio of rate laws for experiments 4 and 3, we have

$$\frac{\text{rate}_4}{\text{rate}_3} = \frac{k\ [A]_4^{\,n}[B]_4^{\,m}}{k\ [A]_3^{\,n}[B]_3^{\,m}}$$

The concentrations of A cancel, since $[A]_4 = [A]_3$, and both k's cancel, because the rate constant is constant, so

$$\frac{\text{rate}_4}{\text{rate}_3} = \left(\frac{[B]_4}{[B]_3}\right)^m$$

For each unique combination of experiments 3, 4, and 5, we have

$$\begin{aligned} 4.0 &= 2.0^m \qquad &&\text{(for experiments 4 and 3)} \\ 9.0 &= 3.0^m \qquad &&\text{(for experiments 5 and 3)} \end{aligned}$$

The only value of m that makes these equations true is $m = 2$, so the reaction must be second order with respect to B.

If the value for the exponent is not obvious, we can also determine it by taking advantage of one of the mathematical properties of logarithms. If we take the preceding equation,

■ There is more information on using logarithms in the Appendix A.

$$\frac{\text{rate}_4}{\text{rate}_3} = \left(\frac{[B]_4}{[B]_3}\right)^m$$

and take the logarithm of both sides,

$$\log\left(\frac{\text{rate}_4}{\text{rate}_3}\right) = \log\left(\frac{[B]_4}{[B]_3}\right)^m$$

then we can move the exponent, m, outside the log term so that it multiplies the log of the ratio of the concentrations by m:

$$\log\left(\frac{\text{rate}_4}{\text{rate}_3}\right) = m\left[\log\left(\frac{[B]_4}{[B]_3}\right)\right]$$

For example, using the data from experiments 5 and 4 from Table 14.3,

$$\begin{aligned} 2.25 &= 1.5^m \\ \log(2.25) &= m\log(1.5) \\ 0.352 &= m(0.176) \\ m &= \frac{0.352}{0.176} = 2 \end{aligned}$$

Having determined the exponents for the concentration terms, we now know that the rate law for the reaction must be

$$\text{rate} = k\,[A]^1\,[B]^2 = k\,[A]\,[B]^2$$

To calculate the value of k, we substitute rate and concentration data into the rate law for any one of the sets of data.

$$k = \frac{\text{rate}}{[A]\,[B]^2}$$

Using the data from the first set in Table 14.3,

$$\begin{aligned} k &= \frac{0.20 \text{ mol L}^{-1}\text{ s}^{-1}}{(0.10 \text{ mol L}^{-1})(0.10 \text{ mol L}^{-1})^2} \\ &= \frac{0.20 \text{ mol L}^{-1}\text{ s}^{-1}}{0.0010 \text{ mol}^3\text{ L}^{-3}} \end{aligned}$$

After simplifying the units by cancellation, the value of k with the correct units is

$$k = 2.0 \times 10^2 \text{ L}^2\text{ mol}^{-2}\text{ s}^{-1}$$

Table 14.4 summarizes the reasoning used to determine the order with respect to each reactant from experimental data.

Table 14.4 Relationship between the Order of a Reaction and Changes in Concentration and Rate

Factor by Which the Concentration Is Changed	Factor by Which the Rate Changes	Exponent on the Concentration Term in the Rate Law
2	Rate is unchanged.	0
3		0
4		0
2	$2 = 2^1$	1
3	$3 = 3^1$	1
4	$4 = 4^1$	1
2	$4 = 2^2$	2
3	$9 = 3^2$	2
4	$16 = 4^2$	2
2	$8 = 2^3$	3
3	$27 = 3^3$	3
4	$64 = 4^3$	3

Practice Exercises

14.10 | Use the data from the other four experiments in Table 14.3 to calculate *k* for this reaction. What do you notice about the values of *k*? What are the units for *k*? (*Hint:* Don't forget the exponents in the rate law.)

14.11 | Use the rate law determined in Practice Exercise 14.10 to describe what will happen to the reaction rate under the following conditions: (a) the concentration of *B* is tripled, (b) the concentration of *A* is tripled, and (c) the concentration of *A* is tripled and the concentration of *B* is halved.

Example 14.5

Determining the Exponents of a Rate Law

Sulfuryl chloride, SO_2Cl_2, is used to manufacture the antiseptic chlorophenol. The following data were collected on the decomposition of SO_2Cl_2 at a certain temperature.

$$SO_2Cl_2(g) \longrightarrow SO_2(g) + Cl_2(g)$$

Initial Concentration of SO_2Cl_2 (mol L^{-1})	Initial Rate of Formation of SO_2 (mol L^{-1} s^{-1})
0.100	2.2×10^{-6}
0.200	4.4×10^{-6}
0.300	6.6×10^{-6}

What are the rate law and the value of the rate constant for this reaction?

Analysis: We are asked to write the rate law for the decomposition of SO_2Cl_2, and we can only do this by using the experimental data. After we determine the exponents for the rate law, we also have to determine the rate constant, *k*, for the rate law, including the units. Finally, we will use the rate law we determined and data from one of the experiments to calculate *k*.

Assembling the Tools: The first tool we will use is the general form of the expected rate law so we can see which exponents have to be determined. Then we use the tool for determining the order of reactions from the data in Table 14.4 since the concentration is changing by a factor of two for the second reaction and three for the third reaction.

Solution: We expect the rate law to have the form

$$\text{rate} = k\,[SO_2Cl_2]^x$$

Let's examine the data from the first two experiments. Notice that when we double the concentration from 0.100 *M* to 0.200 *M*, the initial rate doubles (from 2.2×10^{-6} mol L^{-1} s^{-1} to 4.4×10^{-6} mol L^{-1} s^{-1}). If we look at the first and third experiments, we see that when the concentration triples (from 0.100 *M* to 0.300 *M*), the rate also triples (from 2.2×10^{-6} mol L^{-1} s^{-1} to 6.6×10^{-6} mol L^{-1} s^{-1}). This behavior tells us that the reaction must be first order in the SO_2Cl_2 concentration. The rate law is therefore

■ We could also use Experiments 2 and 3. From the second to the third, the rate increases by the same factor, 1.5, as the concentration, so by these data, too, the reaction must be first order.

$$\text{rate} = k\,[SO_2Cl_2]^1 = k\,[SO_2Cl_2]$$

To evaluate *k*, we can use any of the three sets of data. Choosing the first,

$$\begin{aligned} k &= \frac{\text{rate}}{[SO_2Cl_2]} \\ &= \frac{2.2 \times 10^{-6}\ \cancel{\text{mol L}^{-1}}\ \text{s}^{-1}}{0.100\ \cancel{\text{mol L}^{-1}}} = 2.2 \times 10^{-5}\ \text{s}^{-1} \end{aligned}$$

Is the Answer Reasonable? We should get the same value of *k* by picking any other pair of rates and concentrations. Using the data from both the second and third experiments we get 2.2×10^{-5} s^{-1} each time. The fact that we get the same result each time confirms that both our rate law and calculations are reasonable.

Example 14.6
Determining the Exponents of a Rate Law

The following data were measured for the reduction of nitric oxide with hydrogen:

$$2H_2(g) + 2NO(g) \longrightarrow N_2(g) + 2H_2O(g)$$

Initial Concentrations (mol L^{-1})		Initial Rate of Formation of H_2O (mol L^{-1} s^{-1})
$[H_2]$	[NO]	
0.10	0.10	1.23×10^{-3}
0.20	0.10	2.46×10^{-3}
0.10	0.27	8.97×10^{-3}

What is the rate law for the reaction?

Analysis: This time we have two reactants. To see how their concentrations affect the rate, we must vary only one concentration at a time. Therefore, we choose two experiments in which the concentration of one reactant doesn't change and examine the effect of a change in the concentration of the other reactant. Then, we repeat the procedure for the second reactant.

Assembling the Tools: We will use the same tools we used in Example 14.5—namely, the general form of the expected rate law and the tool for determining the order of reactions from the experimental data.

Solution: We expect the rate law to have the form

$$\text{rate} = k\,[H_2]^m\,[NO]^n$$

Let's look at the first two experiments. Here the concentration of NO remains the same, so the rate is being affected by the change in the H_2 concentration. When we double the H_2 concentration, the rate doubles, so the reaction is first order with respect to H_2. This means $m = 1$.

Next, we need to pick two experiments in which the H_2 concentration doesn't change. Working with the first and third, $[NO]_1 = 0.10$ mol L^{-1} and $[NO]_3 = 0.27$ mol L^{-1}. The initial rate of reaction for the first reaction is 1.23×10^{-3} mol L^{-1} s^{-1} and for the third reaction it is 8.97×10^{-3} mol L^{-1} s^{-1}.

■ The subscripts attached to the concentrations indicate from which experiment we draw the data.

These are not simple numbers to work with, so we will have to use the ratio of the two reaction rates,

$$\frac{\text{rate}_1}{\text{rate}_3} = \frac{\cancel{k}\ \cancel{[H_2]_1^1}\,[NO]_1^n}{\cancel{k}\ \cancel{[H_2]_3^1}\,[NO]_3^n}$$

We can eliminate k and $[H_2]$, since the values are equal, in which case

$$\frac{\text{rate}_1}{\text{rate}_3} = \frac{[NO]_1^n}{[NO]_3^n}$$

$$\log\left(\frac{\text{rate}_1}{\text{rate}_3}\right) = \log\left(\frac{[NO]_1}{[NO]_3}\right)^n = n\log\left(\frac{[NO]_1}{[NO]_3}\right)$$

Now we can use the experimental data to find the value for n:

$$\log\left(\frac{1.23 \times 10^{-3}}{8.97 \times 10^{-3}}\right) = n\,\log\left(\frac{0.10}{0.27}\right)$$

$$\log(0.137) = n\log(0.37)$$

$$-0.863 = n\,(-0.431)$$

$$n = 2$$

Therefore, the rate law for the reaction is

$$\text{rate} = k\,[H_2]\,[NO]^2$$

■ **Is the Answer Reasonable?** The only data that we haven't used as a pair are the data for the second and third reactions. The value of [NO] increases by 2.7 in going from the second to the third set of data, so this should multiply the rate by 2.7^2 or 7.29, if we've found the right exponents. However, the value for $[H_2]$ halves at the same time, so this should take a rate that is otherwise four times as large and cut it in half. The net effect, then, is to make the rate of the third reaction two times as large as that of the second reaction, which is the observed rate change.

Practice Exercises

14.12 | The following reaction is investigated to determine its rate law:

$$2NO(g) + 2H_2(g) \longrightarrow N_2(g) + 2H_2O(g)$$

Experiments yielded the following results:

Initial Concentrations (mol L^{-1})		Initial Rate of Formation of N_2 (mol L^{-1} s^{-1})
[NO]	$[H_2]$	
0.40×10^{-4}	0.30×10^{-4}	1.0×10^{-8}
0.80×10^{-4}	0.30×10^{-4}	4.0×10^{-8}
0.80×10^{-4}	0.60×10^{-4}	8.0×10^{-8}

(a) What is the rate law for the reaction? (b) What is the value of the rate constant? (c) What are the units for the rate constant? (*Hint:* Identify the two experiments where only [NO] changes and the two experiments where only the $[H_2]$ varies.)

14.13 | Ordinary sucrose (table sugar) reacts with water in an acidic solution to produce two simpler sugars, glucose and fructose, that have the same molecular formulas.

$$\underset{\text{sucrose}}{C_{12}H_{22}O_{11}} + H_2O \longrightarrow \underset{\text{glucose}}{C_6H_{12}O_6} + \underset{\text{fructose}}{C_6H_{12}O_6}$$

In a series of experiments, the following data were obtained:

Initial Sucrose Concentration (mol L^{-1})	Rate of Formation of Glucose (mol L^{-1} s^{-1})
0.10	6.17×10^{-5}
0.36	2.22×10^{-4}
0.58	3.58×10^{-4}

(a) What is the order of the reaction with respect to sucrose? (b) What is the value of the rate constant, and what are its units?

14.14 | A certain reaction has the following equation: $A + B \longrightarrow C + D$.
Experiments yielded the following results:

Initial Concentrations (mol L^{-1})		Initial Rate of Formation of *C* (mol L^{-1} s^{-1})
[*A*]	[*B*]	
0.40	0.30	1.00×10^{-4}
0.60	0.30	2.25×10^{-4}
0.80	0.60	1.60×10^{-3}

(a) What is the rate law for the reaction? (b) What is the value of the rate constant? (c) What are the units for the rate constant? (d) What is the overall order of this reaction? (*Hint:* Solve for the exponent of [*A*], then use it to solve for the exponent of [*B*].)

14.4 | Integrated Rate Laws

The rate law tells us how the speed of a reaction varies with the concentrations of the reactants. Often, however, we are more interested in how the concentrations change over time. For instance, if we were preparing some compound, we might want to know how long it will take for the reactant concentrations to drop to some particular value, so we can decide when to isolate the products.

The relationship between the concentration of a reactant and time can be derived from a rate law using calculus. By summing or "integrating" the instantaneous rates of a reaction from the start of the reaction until some specified time t, we can obtain *integrated rate laws* that quantitatively give concentration as a function of time. The form of the integrated rate law depends on the order of the reaction. The mathematical expressions that relate concentration and time in complex reactions can be complicated, so we will concentrate on using integrated rate laws for a few simple first- and second-order reactions with only one reactant.

First-Order Reactions

A **first-order reaction** is a reaction that has a rate law of the type

$$\text{rate} = k\,[A]$$

Using calculus,[2] the following equation can be derived that relates the concentration of A and time:

Integrated first-order rate law

$$\ln\frac{[A]_0}{[A]_t} = kt \tag{14.5}$$

The symbol "ln" means natural logarithm. The expression to the left of the equals sign is the natural logarithm of the ratio of $[A]_0$ (the initial concentration of A at $t = 0$) to $[A]_t$ (the concentration of A at a time t after the start of the reaction).

We can take the antilogarithm of both sides of Equation 14.5 and rearrange it algebraically to obtain the concentration at time t directly as a function of time:[3]

$$[A]_t = [A]_0\, e^{-kt} \tag{14.6}$$

---

[2] For a first-order reaction, the integrated rate law is obtained by calculus as follows. The instantaneous rate of change of the reactant A is given as

$$\text{rate} = \frac{-d[A]}{dt} = k[A]$$

This can be rearranged to give

$$\frac{d[A]}{[A]} = -k\,dt$$

Next we integrate between $t = 0$ and $t = t$ as the concentration of A changes from $[A]_0$ to $[A]_t$.

$$\int_{[A]_0}^{[A]_t} \frac{d[A]}{[A]} = \int_0^t -k\,dt$$

$$\ln[A]_t - \ln[A]_0 = -k\,t$$

Using the properties of logarithms, this can be rearranged to give

$$\ln\frac{[A]_0}{[A]_t} = k\,t$$

[3] Because of the nature of logarithms, if $\ln x = y$, then $e^{\ln x} = e^y$. But $e^{\ln x} = x$, so $x = e^y$. A similar relationship exists for common (i.e., base 10) logarithms. If $\log x = y$, then $10^{\log x} = x = 10^y$.

The e in Equation 14.6 is the base of the system of natural logarithms ($e = 2.718\ldots$). Equation 14.6 shows that the concentration of A decreases exponentially with time. Calculations can be done using the exponential form, Equation 14.5, or the logarithmic form, Equation 14.6. When both of the concentrations are known, it is easiest to use Equation 14.5; when we wish to calculate either $[A]_0$ or $[A]_t$, it may be easier to use Equation 14.6.

■ $[A]_t$ decreases exponentially because the product kt increases with time, but its negative value becomes more negative with time. As the exponent of e becomes a larger negative number, the value of the expression becomes smaller.

Example 14.7
Concentration–Time Calculations for First-Order Reactions

Dinitrogen pentoxide is not very stable. In the gas phase or dissolved in a nonaqueous solvent, such as carbon tetrachloride, it decomposes by a first-order reaction into dinitrogen tetroxide and molecular oxygen:

$$2N_2O_5 \longrightarrow 2N_2O_4 + O_2$$

The rate law is

$$\text{rate} = k\,[N_2O_5]$$

At 45 °C, the rate constant for the reaction in carbon tetrachloride is $6.22 \times 10^{-4}\ \text{s}^{-1}$. If the initial concentration of N_2O_5 in a carbon tetrachloride solution at 45 °C is 0.500 M, what will its concentration be after exactly one hour (i.e., 1.00 hr)?

■ **Analysis:** We're dealing with a first-order reaction and the relationship between concentration and time, and we are looking for a concentration after one hour. We are given an initial concentration, 0.500 M, and the rate constant for the reaction, $6.22 \times 10^{-4}\ \text{s}^{-1}$.

■ **Assembling the Tools:** The tool we have to apply is either Equation 14.5 or 14.6, the integrated rate law for first-order reactions. Specifically, we have to solve for an unknown concentration. The easiest form of the equation to use when one of the unknowns is a concentration term is Equation 14.6. In performing the calculation, we have to remember that the unit of k involves seconds, not hours, so we must convert the given time, 1.00 hr, into seconds ($1.00\ \text{hr} = 3.60 \times 10^3\ \text{s}$).

■ **Solution:** Let's begin by listing the data.

$$[N_2O_5]_0 = 0.500\ M \qquad [N_2O_5]_t = ?\ M$$
$$k = 6.22 \times 10^{-4}\ \text{s}^{-1} \qquad t = 3.60 \times 10^3\ \text{s}$$

Using Equation 14.6,[4]

$$\begin{aligned}[N_2O_5]_t &= [N_2O_5]_0\ e^{-kt}\\ &= (0.500\ M) \times e^{-(6.22 \times 10^{-4}\ \text{s}^{-1}) \times (3.60 \times 10^3)\ \text{s}}\\ &= (0.500\ M) \times e^{-2.24}\\ &= (0.500\ M) \times 0.11\\ &= 0.055\ M\end{aligned}$$

■ Calculating $e^{-2.44}$ is a simple operation using a scientific calculator. In most cases it is the inverse of the ln function.

After one hour, the concentration of N_2O_5 will have decreased to 0.0532 M.

The calculation could also have been done using Equation 14.5. We would begin by solving for the concentration ratio, substituting values for k and t:

$$\begin{aligned}\ln\left(\frac{[N_2O_5]_0}{[N_2O_5]_t}\right) &= (6.22 \times 10^{-4}\ \text{s}^{-1}) \times (3.60 \times 10^3\ \text{s})\\ &= 2.24\end{aligned}$$

---

[4] There are special rules for significant figures for logarithms and antilogarithms. In writing the logarithm of a quantity, the number of digits written *after the decimal point* equals the number of significant figures in the quantity. Raising e to the -2.24 power is the same as taking the antilogarithm of -2.24. Because the quantity -2.24 has two digits after the decimal, the antilogarithm, 0.1064 . . ., must be rounded to 0.11 to show just two significant figures.

To take the antilogarithm (antiln), we raise *e* to the 2.24 power:

$$\text{antiln}\left[\ln\left(\frac{[N_2O_5]_0}{[N_2O_5]_t}\right)\right] = \frac{[N_2O_5]_0}{[N_2O_5]_t}$$

$$\text{antiln}\,(2.24) = e^{2.24}$$

$$= 9.4 \text{ (rounding to 2 significant figures)}$$

This means that

$$\frac{[N_2O_5]_0}{[N_2O_5]_t} = 9.4$$

Now, we can substitute the known concentration, $[N_2O_5]_0 = 0.500\ M$. This gives

$$\frac{0.500\ M}{[N_2O_5]_t} = 9.4$$

Solving for $[N_2O_5]_t$ gives

$$[N_2O_5]_t = \frac{0.500\ M}{9.4}$$

$$= 0.053\ M$$

The answers obtained by the two methods differ slightly because of "rounding errors." You can see that using Equation 14.6, the exponential form, is much easier for working this particular problem.

■ **Is the Answer Reasonable?** Notice that the final concentration of N_2O_5, the reactant in the reaction, is *less* than its initial concentration. You'd know that you made a huge mistake if the calculated final concentration was greater than the initial 0.500 *M* because reactants are consumed in chemical reactions. Also, we obtained essentially the same answer using both Equations 14.5 and 14.6, so we can be confident it's correct. (If you're faced with a problem like this, you don't have to do it both ways; we just wanted to show that either equation could be used.)

Practice Exercises

14.15 | When designing a consumer product, it is desirable that it have a two-year shelf life. Often this means that the active ingredient in the product should not decrease by more than 5% in two years. If the reaction is first order, what rate constant must the decomposition reaction of the active ingredient have? (*Hint:* What are the initial and final percentages of active ingredient?)

14.16 | In Practice Exercise 14.13, the reaction of sucrose with water in an acidic solution was described.

$$\underset{\text{sucrose}}{C_{12}H_{22}O_{11}} + H_2O \longrightarrow \underset{\text{glucose}}{C_6H_{12}O_6} + \underset{\text{fructose}}{C_6H_{12}O_6}$$

The reaction is first order with a rate constant of $6.17 \times 10^{-4}\ s^{-1}$ at 35 °C, when $[H^+] = 0.10\ M$. Suppose that in an experiment the initial sucrose concentration was 0.40 *M*. (a) What will the concentration be after exactly 2 hours (i.e., 2.00 h)? (b) How many minutes will it take for the concentration of sucrose to drop to 0.30 *M*?

Determining Rate Constants of First-Order Reactions

Using the properties of logarithms,[5] Equation 14.5 can be rewritten as the following difference in logarithms:

$$\ln[A]_0 - \ln[A]_t = kt$$

---

[5] The logarithm of a quotient, $\ln\frac{a}{b}$, can be written as the difference, $\ln a - \ln b$.

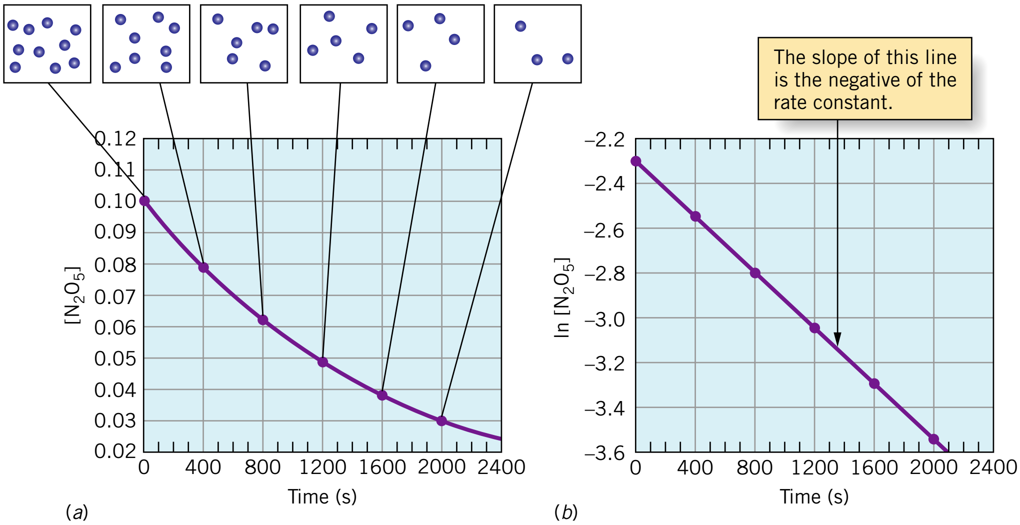


Figure 14.6 | **The decomposition of N_2O_5.** (*a*) A graph of concentration versus time for the decomposition at 45 °C. (*b*) A straight line is obtained if the logarithm of the concentration is plotted versus time. The slope of this line equals the negative of the rate constant for the reaction.

This difference can then be rearranged into a form that corresponds to the equation for a straight line.

$$\begin{array}{ccccc} \ln[A]_t & = & -kt & + & \ln[A]_0 \\ \updownarrow & & \updownarrow\updownarrow & & \updownarrow \\ y & = & mx & + & b \end{array}$$

■ The equation for a straight line is usually written

$$y = mx + b$$

where x and y are variables, m is the slope, and b is the intercept of the line with the y axis.

A plot of the values of $\ln[A]_t$ (vertical axis) versus values of t (horizontal axis) should give a straight line that has a slope equal to $-k$, the negative of the rate constant. Such a plot is illustrated in Figure 14.6 for the decomposition of N_2O_5 into N_2O_4 and O_2 in carbon tetrachloride solvent.

One method of determining whether a reaction is first order with respect to a reactant is to plot the natural logarithm of the concentration as it changes over time and see whether a straight line is obtained.

Half-Life of a Reaction

The *half-life* of a reactant is a convenient way to describe how fast it reacts, particularly for a first-order process. A reactant's **half-life, $t_{1/2}$**, is the amount of time required for half of the reactant to disappear. A rapid reaction has a short half-life because half of the reactant disappears quickly. The equations for half-lives depend on the order of the reaction.

When we state the order of a reaction, we are referring to the overall reaction. Otherwise we state "with respect to" a specific reactant. When a reaction is first order, the half-life of the reactant can be obtained by setting $[A]_t$ equal to one-half of $[A]_0$ and using Equation 14.5.

$$[A]_t = \tfrac{1}{2}[A]_0$$

Substituting $\frac{1}{2}[A]_0$ for $[A]_t$ and $t_{1/2}$ for t in Equation 14.5, we have

$$\ln \frac{[A]_0}{\frac{1}{2}[A]_0} = kt_{1/2}$$

Note that the left-hand side of the equation simplifies to ln 2, so solving the equation for $t_{1/2}$ yields Equation 14.7:

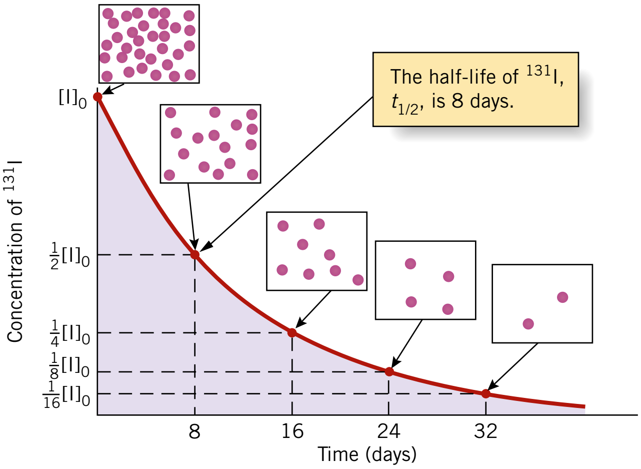
$$\boxed{t_{1/2} = \frac{\ln 2}{k}} \qquad \textbf{(14.7)}$$

■ Because ln 2 equals 0.693, Equation 14.7 is sometimes written $t_{1/2} = \dfrac{0.693}{k}$

TOOLS

Half-lives of first-order reactions

Figure 14.7 | **First-order radioactive decay of iodine-131.** The initial concentration of the isotope is represented by $[I]_0$.



Because k is a constant for a given reaction, the half-life is also a constant for any particular first-order reaction (at any given temperature). Remarkably, in other words, *the half-life of a first-order reaction is not affected by the initial concentration of the reactant.* This can be illustrated by one of the most common first-order events in nature, the change that radioactive isotopes undergo during radioactive "decay." In fact, you may have heard the term *half-life* used in reference to the life spans of radioactive substances.

Iodine-131 is an unstable, radioactive isotope of iodine and undergoes a nuclear reaction, emitting radiation[6] (more information about nuclear chemistry is presented in Chapter 21, Nuclear Chemistry). The intensity of the radiation emitted decreases, or *decays,* with time, as shown in Figure 14.7. Notice that the time it takes for the first half of the ^{131}I to disappear is eight days. During the next eight days, half of the remaining ^{131}I disappears, and so on. Regardless of the initial amount, it takes eight days for half of that amount of ^{131}I to disappear, which means that the half-life of ^{131}I is a constant, and the reaction is first-order.

Example 14.8
Half-Life Calculations

Suppose a patient is given a certain amount of iodine-131 as part of a diagnostic procedure for a thyroid disorder. Given that the half-life of radioactive iodine-131 is 8.02 days, what fraction of the initial iodine-131 would be present in a patient after 25 days if none of it were eliminated through natural body processes?

■ **Analysis:** We've learned that radioactive iodine-131 decays by a first-order process with a constant half-life. We can use the half-life to calculate the rate constant, k, for the reaction and then use the rate constant to calculate the amount of material left.

■ **Assembling the Tools:** We will need to use Equation 14.7 to determine the rate constant from the half-life,

$$t_{1/2} = \frac{\ln 2}{k}$$

and then Equation 14.5 to find the amount of material remaining after 25 days:

$$\ln \frac{[A]_0}{[A]_t} = kt$$

---

[6] Iodine-131 is used in the diagnosis of thyroid disorders. The thyroid gland is a small organ located just below the "Adam's apple" and astride the windpipe. It uses iodide ion to make a hormone, so when a patient is given a dose of $^{131}I^-$ mixed with nonradioactive I^-, both ions are taken up by the thyroid gland. The change in (temporary) radioactivity of the gland is a measure of thyroid activity.

Solution: We will start by finding the first-order rate constant, k, which we can obtain from the half-life by rearranging Equation 14.7 (note that we keep one extra significant figure until the end):

$$k = \frac{\ln 2}{t_{1/2}} = \frac{0.693}{8.02 \text{ days}} = 0.0864 \text{ day}^{-1}$$

Then, we can use Equation 14.5 to compute the fraction, $\frac{[A]_0}{[A]_t}$,

$$\ln\frac{[A]_0}{[A]_t} = kt = (0.0864 \text{ day}^{-1})(25 \text{ days}) = 2.160$$

This is a logarithm, so it should have three decimal places for the three significant figures.

Taking the antilogarithm of both sides, we have

$$\frac{[A]_0}{[A]_t} = e^{2.160} = 8.67 = 8.7$$

The initial concentration, $[A]_0$, is 8.7 times as large as the concentration after 25.0 days, so the fraction remaining after 25 days is

$$\frac{1}{8.7} \text{ or } 0.11$$

Is the Answer Reasonable? A period of 24 days is exactly three 8.0 day half-lives, and 25 is very close to 24. Therefore, we can use the value of 24 days and apply the half-life concept three times. If we take the fraction initially present to be 1, we can set up the following table:

Half-life	0	1	2	3
Fraction	1	$\frac{1}{2}$	$\frac{1}{4}$	$\frac{1}{8}$

The fraction remaining after n half-lives is $\left(\frac{1}{2}\right)^n$, or simply $\frac{1}{2^n}$.

Half of the iodine-131 is lost in the first half-life, half of that disappears in the second half-life, and so on. Therefore, the fraction remaining after three half-lives is $\frac{1}{8}$ which is very close to our value of $\frac{1}{8.7}$.

Practice Exercises

14.17 | In Practice Exercise 14.13, the reaction of sucrose with water was found to be first order with respect to sucrose. The rate constant under the conditions of the experiments was 6.17×10^{-4} s^{-1}. Calculate the value of $t_{1/2}$ for this reaction in minutes. How many minutes would it take for three-quarters of the sucrose to react? (*Hint*: What fraction of the sucrose remains?)

14.18 | From the answer to Practice Exercise 14.15, determine the half-life of an active ingredient that has a shelf life of 2.00 years.

14.19 | The radioactive isotope, phosphorus-32, has a half-life of 14.26 days. How much phosphorus-32 will remain after 60 days?

Carbon-14 Dating

Carbon-14 is a radioactive isotope with a half-life of 5730 years and a rate constant, k, of 1.21×10^{-4} yr^{-1}. It is formed in small amounts in the upper atmosphere by the action of cosmic rays on nitrogen atoms. Once formed, the carbon-14 diffuses into the lower atmosphere. It becomes oxidized to carbon dioxide and enters earth's biosphere by means of photosynthesis. Carbon-14 thus becomes incorporated into plant substances and into the materials of animals that eat plants. As the carbon-14 decays, more is ingested by the living thing. The net effect is an overall steady-state availability of carbon-14 in the global system. As long as the plant or animal is alive, its ratio of carbon-14 atoms to carbon-12 atoms is constant. At death, an organism's remains have as much carbon-14 as they can ever have, and they now slowly lose this carbon-14 by radioactive decay. The decay is a first-order process with a rate independent of the *number* of original carbon atoms. The ratio of carbon-14 to carbon-12, therefore, can be related to the years that have elapsed between the time of death and the time of the measurement. The critical assumption in carbon-14 dating is that the steady-state availability of carbon-14 from the atmosphere has remained largely unchanged since the specimen stopped living.[7]

- In all dating experiments, the amounts of sample are extremely small, and extraordinary precautions must be taken to avoid contaminating specimens with "modern" materials.

- Willard F. Libby won the Nobel Prize in chemistry in 1960 for his discovery of the carbon-14 method for dating ancient objects.

In contemporary biological samples, the ratio $^{14}C/^{12}C$ is about 1.2×10^{-12}. Thus, each fresh 1.0 g sample of biological carbon in equilibrium with the $^{14}CO_2$ of the atmosphere has a ratio of 5.8×10^{10} atoms of carbon-14 to 4.8×10^{22} atoms of carbon-12. The ratio decreases by a factor of 2 for each half-life period of ^{14}C.

The dating of an object makes use of the fact that radioactive decay is a first-order process. If we let r_0 stand for the $^{14}C/^{12}C$ ratio at the time of death of the carbon-containing species and r_t stand for the $^{14}C/^{12}C$ ratio now, after the elapse of t years, we can substitute into Equation 14.5 to obtain

$$\ln\frac{r_0}{r_t} = kt \qquad \textbf{(14.8)}$$

where k is the rate constant for the decay (the *decay constant* for ^{14}C) and t is the elapsed time. We can now substitute $1.21 \times 10^{-4}\ \text{yr}^{-1}$ for k into Equation 14.8 to give

Carbon-14 dating

$$\ln\frac{r_0}{r_t} = (1.21 \times 10^{-4}\ \text{yr}^{-1})t \qquad \textbf{(14.9)}$$

Equation 14.9 can be used to calculate the age of a once-living object if its current $^{14}C/^{12}C$ ratio can be measured.

We have to realize here that we are not using the number of disintegrating nuclei, but the ratio of $^{14}C/^{12}C$, which is an intensive property. We need to use intensive properties to calculate the age of the object, since the size of the sample cannot be a determining factor.

Example 14.9
Calculating the Age of an Object by ^{14}C Dating

Using a mass spectrometer, a sample of an ancient wooden object was found to have a ratio of ^{14}C to ^{12}C equal to 3.3×10^{-13} as compared to a contemporary biological sample, which has a ratio of ^{14}C to ^{12}C of 1.2×10^{-12}. What is the age of the object?

Analysis: We are given the ratio of ^{14}C to ^{12}C and asked to find the age of the object.

Assembling the Tools: The tool we will use is Equation 14.9, and substitute the values given with $r_0 = 1.2 \times 10^{-12}$ and $r_t = 3.3 \times 10^{-13}$.

Solution: The contemporary ratio of ^{14}C to ^{12}C was given as 1.2×10^{-12}. This corresponds to r_0 in Equation 14.9. Substituting into Equation 14.9 gives

$$\ln\frac{1.2 \times 10^{-12}}{3.3 \times 10^{-13}} = (1.21 \times 10^{-4}\ \text{yr}^{-1})t$$
$$\ln(3.6) = (1.21 \times 10^{-4}\ \text{yr}^{-1})t$$

Solving for t gives an age of 1.1×10^4 years (11,000 years).

Is the Answer Reasonable? We've been told that the object is ancient, so 11,000 years old seems to make sense. (Also, if you had substituted incorrectly into Equation 14.9, the answer would have been negative, and that certainly doesn't make sense!)

---

[7] The available atmospheric pool of carbon-14 atoms fluctuates somewhat with the intensities of cosmic ray showers, with slow, long-term changes in earth's magnetic field, and with the huge injections of carbon-12 into the atmosphere from the large-scale burning of coal and petroleum in the 1900s. To reduce the uncertainties in carbon-14 dating, results of the method have been correlated with dates made by tree-ring counting. For example, an uncorrected carbon-14 dating of a Viking site at L'Anse aux Meadows, Newfoundland, gave a date of AD 895 ± 30. When corrected, the date of the settlement became AD 997, almost exactly the time indicated in Icelandic sagas for Leif Eriksson's landing at "Vinland," now believed to be the L'Anse aux Meadows site.

Practice Exercises

14.20 | The ^{14}C content of an ancient piece of wood was found to be one-tenth of that in living trees. How many years old is this piece of wood ($t_{1/2} = 5730$ for ^{14}C)? (*Hint:* Recall the relationship between the integrated rate equation and half-life.)

14.21 | The calibration curves for carbon-14 dating are constantly being updated. Before 2010, when using carbon-14 dating, samples that had decayed less than 5% and those that had decayed more than 95% may have had unacceptably large uncertainties. How many years before the present could carbon-14 be used for dating an object using the 5% and 95% limits?

Second-Order Reactions

For simplicity, we will only consider a **second-order reaction** with a rate law with only one reactant,

$$\text{rate} = k\,[B]^2$$

The relationship between concentration and time for a reaction with such a rate law is given by Equation 14.10, an equation that is quite different from that for a first-order reaction.

$$\frac{1}{[B]_t} - \frac{1}{[B]_0} = kt \tag{14.10}$$

TOOLS

Integrated second-order rate law

$[B]_0$ is the initial concentration of B and $[B]_t$ is the concentration at time t.

Example 14.10

Concentration–Time Calculations for Second-Order Reactions

Nitrosyl chloride, NOCl, decomposes slowly to NO and Cl_2:

$$2\text{NOCl} \longrightarrow 2\text{NO} + \text{Cl}_2$$

The rate law for this reaction is second order in NOCl:

$$\text{rate} = k\,[\text{NOCl}]^2$$

The rate constant k equals 0.020 L mol^{-1} s^{-1} at a certain temperature. If the initial concentration of NOCl in a closed reaction vessel is 0.050 M, what will the concentration be after 35 minutes?

Analysis: We're given a rate law that is for a second-order reaction. We must calculate $[\text{NOCl}]_t$, the molar concentration of NOCl, after 35 minutes (i.e., 2100 s).

Assembling the Tools: Our tool for doing this is Equation 14.10, the integrated rate law for second-order reactions.

Solution: Let's begin by tabulating the data:

$$[\text{NOCl}]_0 = 0.050\ M \qquad [\text{NOCl}]_t = ?\ M$$
$$k = 0.020\ \text{L mol}^{-1}\ \text{s}^{-1} \qquad t = 2100\ \text{s}$$

The equation we wish to substitute into is

$$\frac{1}{[\text{NOCl}]_t} - \frac{1}{[\text{NOCl}]_0} = kt$$

Making the substitutions gives

$$\frac{1}{[\text{NOCl}]_t} - \frac{1}{0.050\ \text{mol L}^{-1}} = (0.020\ \text{L mol}^{-1}\ \text{s}^{-1}) \times (2100\ \text{s})$$

Solving for $1/[\text{NOCl}]_t$ gives

$$\frac{1}{[\text{NOCl}]_t} - 20 \text{ L mol}^{-1} = 42 \text{ L mol}^{-1}$$

$$\frac{1}{[\text{NOCl}]_t} = 62 \text{ L mol}^{-1}$$

Taking the reciprocals of both sides gives us the value of $[\text{NOCl}]_t$:

$$[\text{NOCl}]_t = \frac{1}{62 \text{ L mol}^{-1}} = 0.016 \text{ mol L}^{-1} = 0.016\ M$$

The molar concentration of NOCl has decreased from 0.050 *M* to 0.016 *M* after 35 minutes.

■ **Is the Answer Reasonable?** The concentration of NOCl has decreased, so the answer appears to be reasonable.

Practice Exercises

14.22 | For the reaction in Example 14.10, determine how many minutes it would take for the NOCl concentration to drop from 0.040 *M* to 0.010 *M*. (*Hint:* In solving Equation 14.10, time must be a positive value.)

14.23 | A sample of nitrosyl chloride was collected for analysis at 10:35 AM. At 3:15 PM the same day, the sample was analyzed and was found to contain 0.0035 *M* NOCl. What was the concentration of NOCl at the time the sample was collected?

Second-Order Rate Constants

The rate constant *k* for a second-order reaction, one with a rate following Equation 14.10, can be determined graphically by a method similar to that used for a first-order reaction. We can rearrange Equation 14.10 so that it corresponds to an equation for a straight line:

$$\begin{array}{ccccc} \dfrac{1}{[B]_t} & = & kt & + & \dfrac{1}{[B]_0} \\ \updownarrow & & \updownarrow\updownarrow & & \updownarrow \\ y & = & mx & + & b \end{array}$$

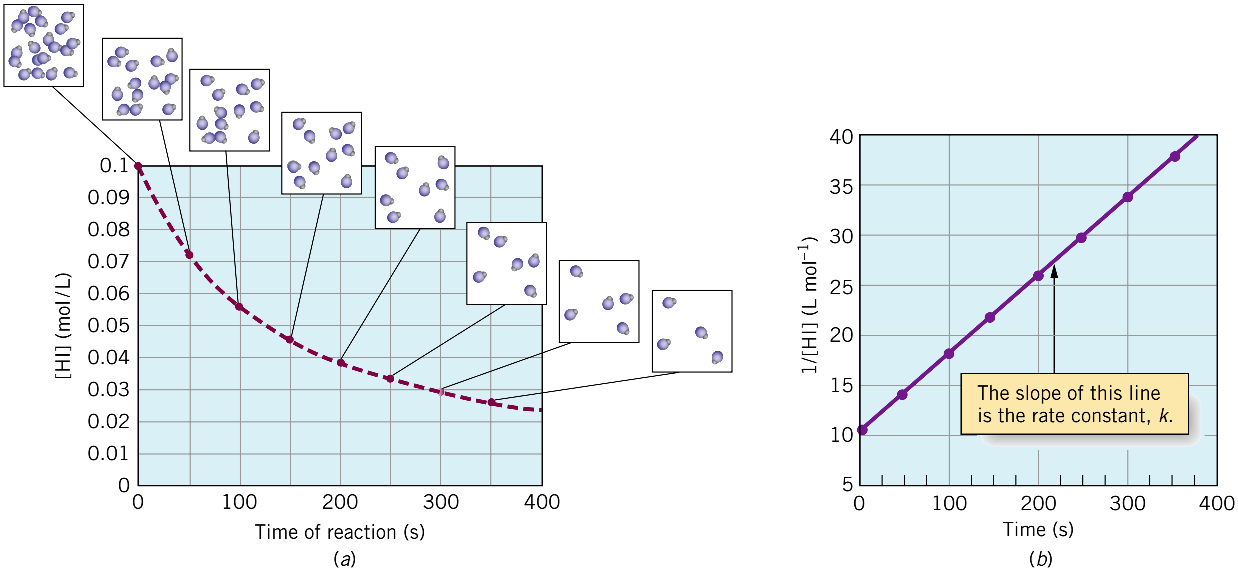
When a reaction is second order, a plot of $1/[B]_t$ versus *t* should yield a straight line having a slope *k*. This is illustrated in Figure 14.8 for the decomposition of HI, using data in Table 14.1.

Half-Lives of Second-Order Reactions

The half-life of a second-order reaction *does* depend on initial reactant concentrations. We can see this by examining Figure 14.8, which follows the decomposition of gaseous HI, a second-order reaction. The reaction begins with a hydrogen iodide concentration of 0.10 *M*. After 125 seconds, the concentration of HI drops to 0.050 *M*, so 125 s is the observed half-life when the initial concentration of HI is 0.10 *M*. If we then take 0.050 *M* as the next "initial" concentration, we find that it takes 250 seconds (at a *total* elapsed time of 375 seconds) to drop to 0.025 *M*. If we cut the initial concentration in half, from 0.10 *M* to 0.050 *M*, the half-life doubles, from 125 to 250 seconds.

It can be shown that for a second-order reaction of the type we're studying, the half-life is inversely proportional to the initial concentration of the reactant. The half-life is related to the rate constant by Equation 14.11.

$$t_{1/2} = \frac{1}{k \times (\text{initial concentration of reactant})} \tag{14.11}$$



The slope of this line is the rate constant, *k*.

Figure 14.8 | **Second-order kinetics.** (*a*) A graph of concentration versus time for the decomposition of HI for the data in Table 14.1. (*b*) A straight line is obtained if 1/[HI] is plotted versus time.

Zero-Order Reactions

Zero-order reactions have an exponent of zero on the concentration term, so they do not depend on the concentration of the reactant:

$$\text{rate} = k\,[A]^0 = k$$

When the concentration of the reactant is plotted versus time, it will give a straight line if the reaction is a zero-order reaction, since the integrated rate law equation is

$$[A]_t = -kt + [A]_0 \tag{14.12}$$

TOOLS

Integrated zero-order rate law

This can also be plotted in a similar fashion to the first-order and second-order reactions, which will give the rate constant, *k*, as the negative of the slope. The half-life expression for a zero-order reaction can be determined by substituting $[A]_t = \frac{1}{2}[A]_0$ into Equation 14.12 and solving the equation to get

$$t_{1/2} = \frac{1}{k}\,\frac{[A]_0}{2}$$

Graphical Interpretation of Orders of Reactions

For zero-order reactions to yield a straight line, the concentration of the reactant is plotted versus time and the negative of the slope is the rate constant. First-order reactions have a linear graph when the natural log of the concentration of the reactant is plotted versus time and the negative slope of the line is the rate constant. Second-order reactions require the inverse of the concentration to be plotted versus time to give a straight line, and the slope of the line is the rate constant. All of this information is summarized in Table 14.5.

Table 14.5 **Graphical Interpretation of Orders of Reactions**

Order of Reaction	Straight-Line Plot	Rate Constant, *k*	Half-Life Dependence
0	$[X]$ versus time	Negative slope of line	Depends on initial concentration
1	$\ln[X]$ versus time	Negative slope of line	No dependence on concentration
2	$1/[X]$ versus time	Slope of line	Depends on initial concentration

Example 14.11
Half-Life Calculations

The reaction $2HI(g) \longrightarrow H_2(g) + I_2(g)$ has the rate law, rate $= k\,[HI]^2$, with $k = 0.079\ L\ mol^{-1}\ s^{-1}$ at 508 °C. What is the half-life for this reaction at this temperature when the initial HI concentration is 0.10 *M*?

Analysis: The rate law tells us that the reaction is second-order, and we are asked for the half-life for this reaction. Keep in mind that for second-order reactions, the half-life depends on the initial concentration.

Assembling the Tools: To calculate the half-life, we need to use Equation 14.11 as the tool to solve this problem.

Solution: The initial concentration is 0.10 mol L^{-1}; $k = 0.079\ L\ mol^{-1}\ s^{-1}$. Substituting these values into Equation 14.11 gives

$$\begin{aligned} t_{1/2} &= \frac{1}{(0.079\ \cancel{L}\ \cancel{mol^{-1}}\ s^{-1})(0.10\ \cancel{mol}\ \cancel{L^{-1}})} \\ &= 1.3 \times 10^2\ s \end{aligned}$$

Is the Answer Reasonable? To estimate the answer, we round the 0.079 to 0.1, so the estimated answer is $\frac{1}{0.1 \times 0.1} = 100$. This is close to our calculated value. In addition, we check that the units cancel to leave only the seconds units. Both of these checks support our answer.

Practice Exercises

14.24 | The reaction $2NO_2 \longrightarrow 2NO + O_2$ is second order with respect to NO_2. If the initial concentration of $NO_2(g)$ is 6.54×10^{-4} mol L^{-1}, what is the rate constant if the initial reaction rate is 4.42×10^{-7} mol L^{-1} s^{-1}? What is the half-life of this system? (*Hint:* Start by setting up and solving the rate law before the integrated equation.)

14.25 | Suppose that the value of $t_{1/2}$ for a certain reaction was found to be independent of the initial concentration of the reactants. What could you say about the order of the reaction? Justify your answer.

14.5 | Molecular Basis of Collision Theory

As a rule, the rate of a chemical reaction increases by a factor of about 2 or 3 for each 10 °C increase in temperature, although the actual amount of increase differs from one reaction to another. Temperature evidently has a strong effect on reaction rate. To understand why, we need to develop theoretical models that explain our observations. One of the simplest models is called *collision theory*.

Collision Theory

The basic postulate of **collision theory** is that the rate of a reaction is proportional to the number of *effective* collisions per second among the reactant molecules. An **effective collision** is one that actually gives product molecules. Anything that can increase the frequency of effective collisions should, therefore, increase the rate.

One of the several factors that influences the number of effective collisions per second is *concentration*. As reactant concentrations increase, the number of collisions per second of all types, including effective collisions, cannot help but increase. We'll return to the significance of concentration in Section 14.8.

Not *every* collision between reactant molecules actually results in a chemical change. We know this because the reactant atoms or molecules in a gas or a liquid undergo an enormous number of collisions per second with each other. If every collision were effective, all reactions would be over in an instant. *Only a very small fraction of all of the collisions can really lead to a net change.* Why is this so?

Molecular Orientation

In most reactions, when two reactant molecules collide, they must be oriented correctly for a reaction to occur. For example, the reaction represented by the following balanced chemical equation,

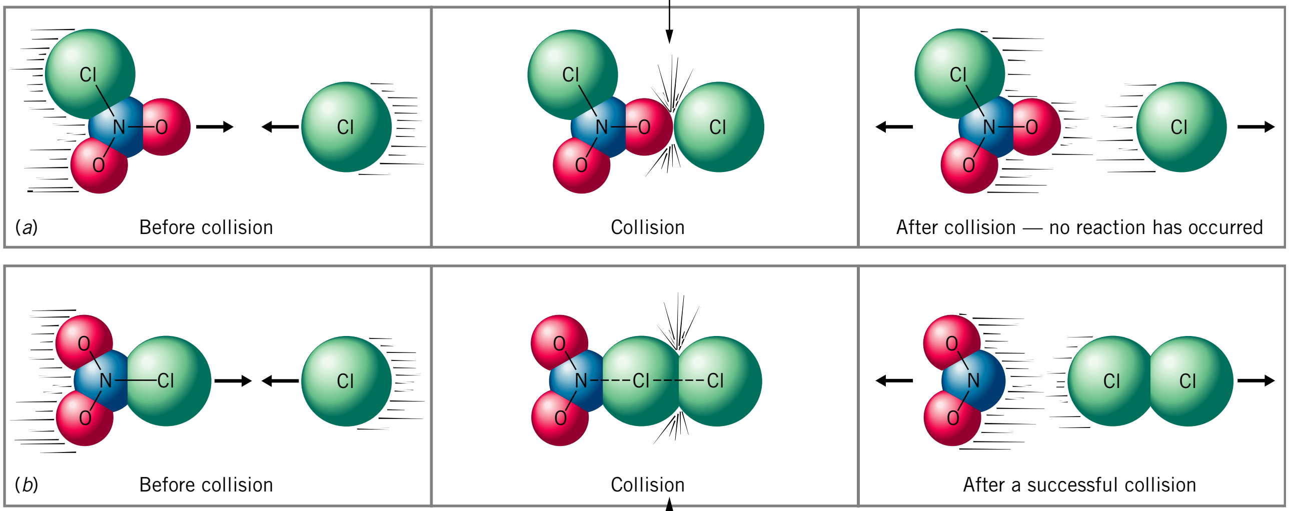
$$2NO_2Cl \longrightarrow 2NO_2 + Cl_2$$

appears to proceed by a two-step sequence of reactions. One step involves the collision of an NO_2Cl molecule with a chlorine atom:

$$NO_2Cl + Cl \longrightarrow NO_2 + Cl_2$$

The orientation of the NO_2Cl molecule, when hit by the Cl atom, is important (see Figure 14.9). The poor orientation shown in Figure 14.9*a* cannot result in the formation

The orientation of this collision cannot produce a Cl_2 molecule.



Cl
N
O
O
Cl
(a) Before collision
Collision
After collision — no reaction has occurred
(b) Before collision
Collision
After a successful collision

The orientation of this collision permits reaction and produces NO_2 and Cl_2.

Figure 14.9 | **The importance of molecular orientation during a collision in a reaction.** The key step in the decomposition of NO_2Cl to NO_2 and Cl_2 is the collision of a Cl atom with a NO_2Cl molecule. (*a*) A poorly oriented collision. (*b*) An effectively oriented collision.

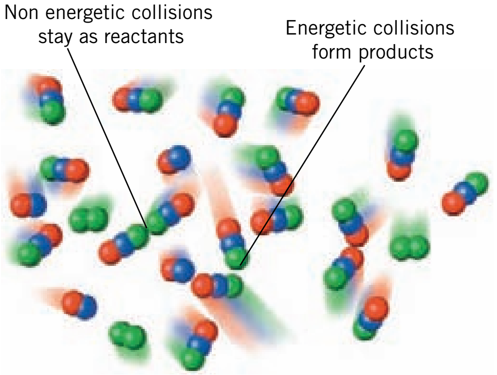
of Cl_2 because the two Cl atoms are not being brought close enough together for a new Cl—Cl bond to form as an N—Cl bond breaks. Figure 14.9*b* shows the necessary orientation if the collision of NO_2Cl and Cl is to effectively lead to products.

Molecular Kinetic Energy

Not all collisions, even those correctly oriented, are energetic enough to result in products, and this is the major reason that only a small percentage of all collisions actually lead to chemical change. The colliding particles must carry into the collision a certain minimum combined molecular kinetic energy, called the **activation energy, E_a**. In a successful collision, activation energy changes over to potential energy as the particles hit each other and chemical bonds in the reactants reorganize into those of the products. For most chemical reactions, the activation energy is quite large, and only a small fraction of all well-oriented, colliding molecules have it.

■ At the start of the reaction described by Figure 14.5, only about one of every billion billion (10^{18}) collisions leads to a net chemical reaction. In each of the other collisions, the reactant molecules just bounce off each other.

We can understand the existence of activation energy by studying in detail what actually takes place during a collision. For old bonds to break and new bonds to form, the atomic nuclei within the colliding particles must get close enough together. The molecules on a collision course must, therefore, be moving with a combined kinetic energy great enough to overcome the natural repulsions between electron clouds. Otherwise, the molecules simply veer away or bounce apart. Only fast molecules with large kinetic energies can collide with enough collision energy to enable their nuclei and electrons to overcome repulsions and thereby reach the positions required for the bond breaking and bond making that the chemical change demands, as shown in Figure 14.10.



Non energetic collisions stay as reactants
Energetic collisions form products

Figure 14.10 | **The energetics of collisions that lead to products.**

Effect of Temperature

With the concept of activation energy, we can now explain why the rate of a reaction increases with increasing temperature. We'll use the two kinetic energy curves in Figure 14.11, each corresponding to a different temperature for the same mixture of reactants. Just like the graphs in Figure 12.18, each curve is a plot of the different *fractions* of all collisions (vertical axis) that have particular values of kinetic energy (horizontal axis). Notice what happens to the plots when the temperature is increased; the maximum point shifts to the right and the curve flattens somewhat. However, *a modest increase in temperature generally does not affect the reaction's activation energy.* In other words, as the curve flattens and shifts to the right with an increase in temperature, the value of E_a stays the same.

■ The fraction of molecules, f_{KE}, having or exceeding the activation energy, E_a, is given by the expression

$$\ln f_{KE} = \frac{-E_a}{RT}$$

The shaded areas under the curves in Figure 14.11 represent the sum of all those fractions of the total collisions that equal or exceed the activation energy. This sum—we could call it the *reacting fraction*—is greater at the higher temperature than at the lower temperature because a significant fraction of the curve shifts beyond the activation energy in even a modest change to a higher temperature. In other words, at the higher temperature, more of the collisions occurring each second results in a chemical change, so the reaction is faster at the higher temperature.

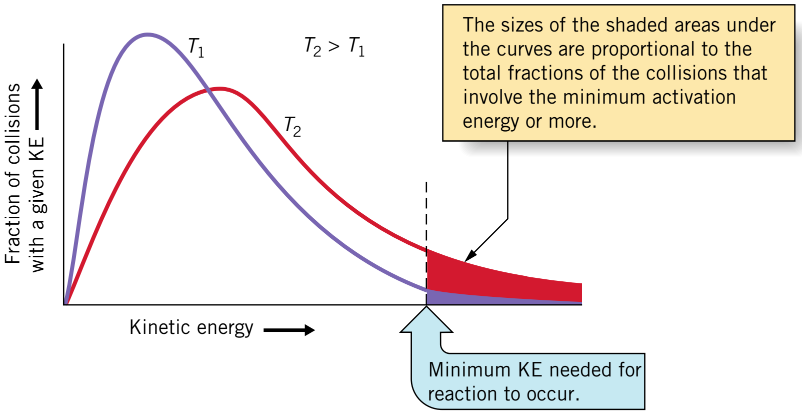


Figure 14.11 | **Kinetic energy distributions for a reaction mixture at two different temperatures.**

On the molecular scale, we can write an equation that summarizes the three factors involved in the collision theory as

$$\text{reaction rate(molecules L}^{-1}\ \text{s}^{-1}) = N \times f_{\text{orientation}} \times f_{\text{KE}}$$

where N represents the collisions per second per liter of the mixture, which is approximately $10^{27}\ \text{s}^{-1}$. The two other terms represent the fraction of collisions with the correct orientation, $f_{\text{orientation}}$, and the fraction of collisions with the required total kinetic energy, f_{KE}. To convert this to the laboratory scale where the rate of the reaction has units of mol $\text{L}^{-1}\ \text{s}^{-1}$, we divide the equation by Avogadro's number:

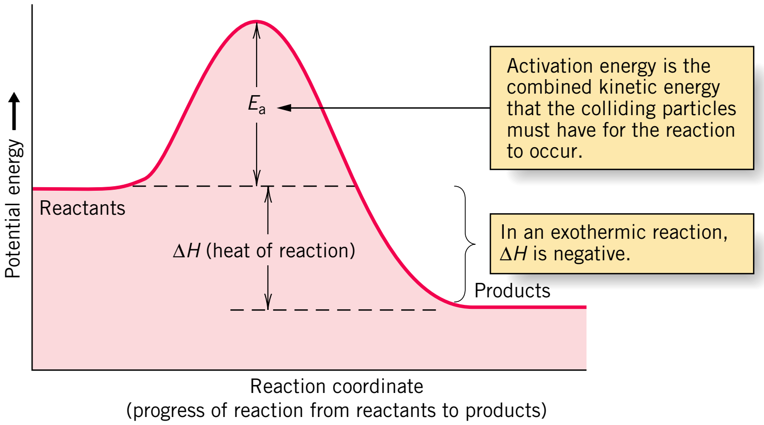
$$\text{reaction rate (mol L}^{-1}\ \text{s}^{-1}) = \frac{\text{reaction rate(}\cancel{\text{molecules}}\ \text{L}^{-1}\ \text{s}^{-1})}{6.02 \times 10^{23}\ (\cancel{\text{molecules}}\ \text{mol}^{-1})}$$

14.6 | Molecular Basis of Transition State Theory

Transition state theory is used to explain in detail what happens when reactant molecules come together in a collision. Most often, those in a head-on collision slow down, stop, and then fly apart unchanged. When a collision does cause a reaction, the particles that separate are those of the products. Regardless of what happens to them, however, as the molecules on a collision course slow down, their total kinetic energy decreases as it changes into potential energy (PE). It's like the momentary disappearance of the kinetic energy of a tennis ball when it hits the racket. In the deformed racket and ball, this energy becomes potential energy, which soon changes back to kinetic energy as the ball takes off in a new direction.

Potential Energy Diagrams

To visualize the relationship between activation energy and the development of total potential energy, we sometimes use a *potential energy diagram* (Figure 14.12). The vertical axis represents changes in *potential* energy as the *kinetic* energy of the colliding particles changes over to this form. The horizontal axis is called the **reaction coordinate**, and it represents the extent to which the reactants have changed to the products. It helps us follow the path taken by the reaction as reactant molecules come together and change into product molecules. Activation energy appears as a potential energy "hill" or barrier between the reactants and products. Only colliding molecules, properly oriented, which can deliver sufficient kinetic energy that can be converted into potential energy at least as large as E_a, are able to climb over the hill and produce products.

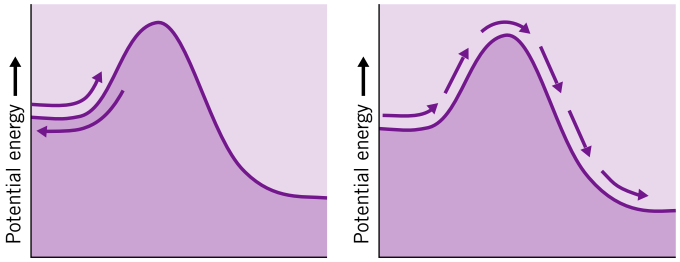


Potential energy ⟶
E_a
Reactants
ΔH (heat of reaction)
Products
Reaction coordinate
(progress of reaction from reactants to products)

Activation energy is the combined kinetic energy that the colliding particles must have for the reaction to occur.

In an exothermic reaction, ΔH is negative.

Figure 14.12 | **Potential energy diagram for an exothermic reaction.**



(*a*) An unsuccessful collision; the colliding molecules separate unchanged.

(*b*) A successful collision; the activation energy barrier is crossed and the products are formed.

Figure 14.13 | **The difference between an unsuccessful and a successful collision.**

We can use a potential energy diagram to follow the progress of both an unsuccessful and a successful collision (see Figure 14.13). As two reactant molecules collide, we say that they begin to climb the potential energy barrier as they slow down and experience the conversion of their kinetic energy into potential energy. However, if their combined initial kinetic energies are less than E_a, the molecules are unable to reach the top of the hill (Figure 14.13*a*). Instead, they fall back toward the reactants. They bounce apart, chemically unchanged, with their original total kinetic energy; no net reaction has occurred. On the other hand, if the combined kinetic energy of the colliding molecules equals or exceeds E_a, and if the molecules are oriented properly, they are able to pass over the activation energy barrier and form product molecules (Figure 14.13*b*).

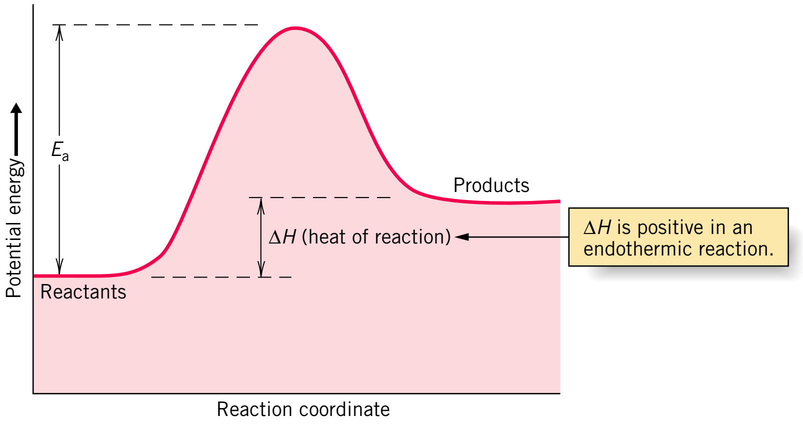
Potential Energy Diagrams and Heat of Reaction

A reaction's potential energy diagram, such as that of Figure 14.12, helps us to visualize the *heat of reaction*, ΔH, a concept introduced in Chapter 7. It's the difference between the potential energy of the products and the potential energy of the reactants. Figure 14.12 shows the potential energy diagram for an *exothermic* reaction because the products have a *lower* potential energy than the reactants. In such a system, the net decrease in potential energy appears as an increase in the molecular kinetic energy of the emerging product molecules. The temperature of the system increases during an exothermic reaction because the average molecular kinetic energy of the system increases.

A potential energy diagram for an endothermic reaction is shown in Figure 14.14. Now, the products have a *higher* potential energy than the reactants and, in terms of the heat of reaction, a net input of energy is needed to form the products. Endothermic reactions produce a cooling effect as they proceed because there is a net conversion of molecular kinetic energy to potential energy. As the *total* molecular kinetic energy decreases, the *average* molecular kinetic energy decreases as well, and the temperature drops.

Notice that E_a for an endothermic process is greater than the heat of reaction. If ΔH is both positive and *high*, E_a must also be high, making such reactions very slow. However, for an exothermic reaction (ΔH is negative), we cannot tell from ΔH how large E_a is. It could be high, making for a slow reaction, despite its being exothermic. If E_a is low, the reaction would be rapid and all its heat would appear quickly.

In Chapter 7, we saw that when the direction of a reaction is reversed, the sign given to the enthalpy change, ΔH, is reversed. In other words, a reaction that is exothermic in the forward direction *must* be endothermic in the reverse direction, and vice versa. This might seem to suggest that reactions are generally reversible. Many are, but if we look again at the energy diagram for a reaction that is exothermic in the forward direction



Potential energy
E_a

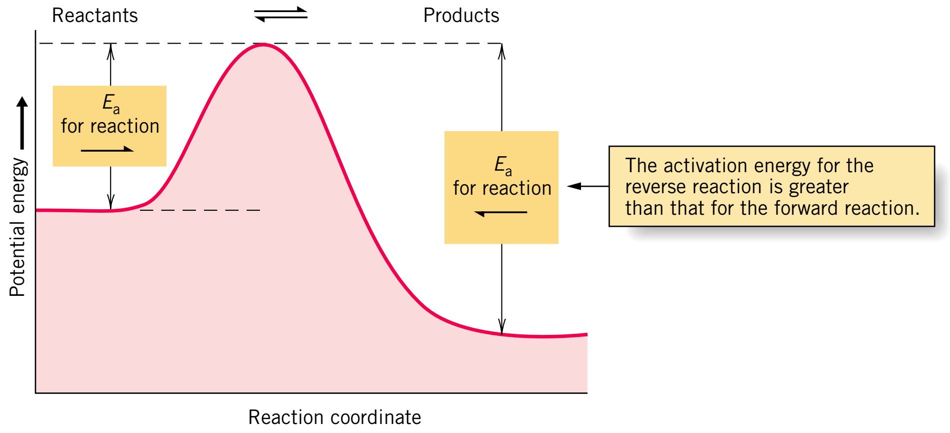
ΔH (heat of reaction)
ΔH is positive in an endothermic reaction.
Reactants
Reaction coordinate

Figure 14.14 | **A potential energy diagram for an endothermic reaction.**



The activation energy for the reverse reaction is greater than that for the forward reaction.

Figure 14.15 | **The activation energy barrier for the forward and reverse reactions.**

(Figure 14.12), we see that the reaction is endothermic in the opposite direction *and must have a significantly higher activation energy* than the forward reaction. What differs most for the forward and reverse directions is the relative height of the activation energy barrier (Figure 14.15).

One of the main reasons for studying activation energies is that they provide information about what actually occurs during an effective collision. For example, in Figure 14.9*b* on page 665, we described a way that NO_2Cl could react successfully with a Cl atom during a collision. During this collision, there is a moment when the N—Cl bond is partially broken and the new Cl—Cl bond is partially formed. This brief moment during a successful collision is called the reaction's **transition state.** The potential energy of the transition state corresponds to the high point on the potential energy diagram (see Figure 14.16). The unstable chemical species that momentarily exists at this instant, $O_2N\cdots Cl\cdots Cl$, with its partially formed and partially broken bonds, is called the **activated complex.**

The size of the activation energy tells us about the relative importance of bond breaking and bond making during the formation of the activated complex. A very high activation energy suggests, for instance, that bond *breaking* contributes very heavily to the formation of the activated complex because bond breaking is an energy-absorbing process. On the other hand, a low activation energy may mean that bonds of about equal strength are being both broken and formed simultaneously.

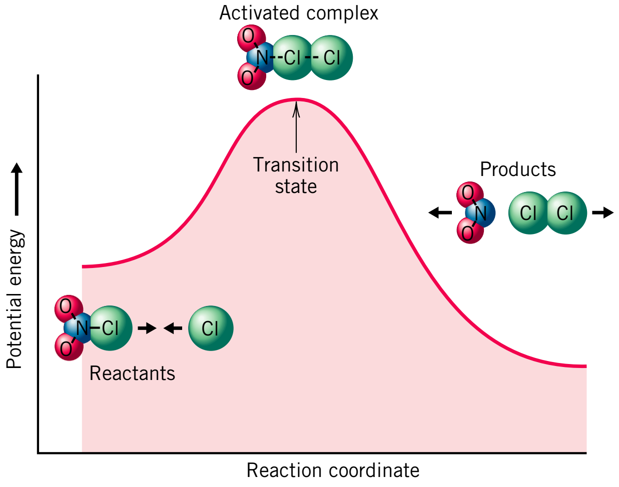


Figure 14.16 | **The transition state and the activated complex.** Formation of an activated complex in the reaction between NO_2Cl and Cl.

$$NO_2Cl + Cl \longrightarrow NO_2 + Cl_2$$

14.7 | Activation Energies

We've noted that the activation energy is a useful quantity to know because its value can provide clues to the relative importance of bond breaking and bond making during the formation of the activated complex. The value of E_a can be determined by observing how temperature affects the value of the rate constant, k.

The activation energy is linked to the rate constant by a relationship discovered in 1889 by Svante Arrhenius, whose name you may recall from our discussion of electrolytes and acids and bases in Chapter 5. The usual form of the **Arrhenius equation** is

TOOLS

Arrhenius equation

$$k = A\,e^{-E_a/RT} \tag{14.13}$$

where k is the rate constant, e is the base of the natural logarithm system, and T is the Kelvin temperature. A is a proportionality constant sometimes called the **frequency factor** or the **pre-exponential factor**. R is the gas constant, which we'll express in our study of kinetics in energy units—namely, R equals 8.314 J mol^{-1} K^{-1}.[8]

Graphical Determination of Activation Energy

Equation 14.13 is normally used in its logarithmic form. If we take the natural logarithm of both sides, we obtain

$$\ln k = \ln A - E_a/RT$$

Let's rewrite the equation as

$$\ln k = \ln A - (E_a/R) \times (1/T) \tag{14.14}$$

We know that the rate constant k varies with the temperature T, which also means that the quantity $\ln k$ varies with the quantity $(1/T)$. These two quantities—namely, $\ln k$ and $1/T$—are variables, so Equation 14.14 is in the form of an equation for a straight line:

$$\begin{array}{ccccccc} \ln k & = & \ln A & + & (-E_a/R) & \times & (1/T) \\ \updownarrow & & \updownarrow & & \updownarrow & & \updownarrow \\ y & = & b & + & m & & x \end{array}$$

To determine the activation energy, we can make a graph of $\ln k$ versus $1/T$, measure the slope of the line, and then use the relationship,

$$\text{slope} = -E_a/R$$

to calculate E_a. Example 14.12 illustrates how this is done.

Example 14.12

Determining Energy of Activation Graphically

Consider again the decomposition of NO_2 into NO and O_2. The balanced chemical equation is

$$2NO_2(g) \longrightarrow 2NO(g) + O_2(g)$$

The following data were collected for the reaction:

Rate Constant, k (L mol^{-1} s^{-1})	Temperature (°C)
7.8	405
9.9	415
14	425
18	435
24	445

---

[8] The units of R given here are actually SI units—namely, the joule (J), the mole (n), and the kelvin (K). To calculate R in these units we need to go back to the defining equation for the universal gas law:

$$R = PV/nT$$

In Chapter 11 we learned that the standard conditions of pressure and temperature are 1 atm and 273.15 K; we expressed the standard molar volume in liters—namely, 22.414 L. But 1 atm equals 1.01325×10^5 N m^{-2}, where N is the SI unit of force, the newton, and m is the meter, the SI unit of length. Thus, m^2 is area given in SI units. From Chapter 11, the ratio of force to area given by N m^{-2} is called the pascal, Pa, and force times distance (i.e., N m) defines one unit of energy in the SI and is called the joule, J. In the SI, volume must be expressed as m^3, to employ the SI unit of length to define volume, and 1 L equals 10^{-3} m^3. We can now calculate R in SI units:

$$R = \frac{(1.01325 \times 10^5 \text{ N m}^{-2}) \times (22.414 \times 10^{-3} \text{ m}^3)}{(1 \text{ mol} \times 273.15 \text{ K})}$$
$$= 8.314 \text{ N m mol}^{-1} \text{ K}^{-1} = 8.314 \text{ J mol}^{-1} \text{ K}^{-1}$$

Use the graphical method to determine the activation energy for the reaction in kilojoules per mole.

Analysis: We are asked to plot the given rate constants at different temperatures to determine the activation energy for the reaction from the slope of the graph, which is $-E_a/R$.

Assembling the Tools: Equation 14.14 is the tool that applies, but the use of rate data to determine the activation energy graphically requires that we plot ln *k*, not *k*, versus the *reciprocal* of the *Kelvin* temperature, so we have to convert the given data into ln *k* and $1/T$ before we can construct the graph.

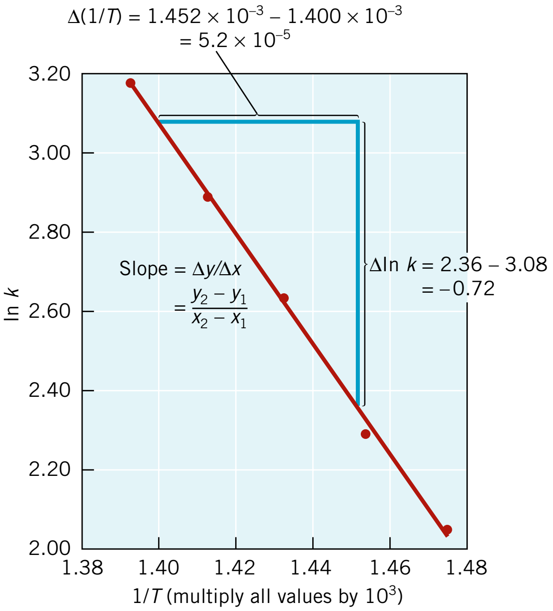
Solution: To illustrate, using the first set of data, the conversions are

$$\ln k = \ln(7.8) = 2.05$$

$$\frac{1}{T} = \frac{1}{(405 + 273)\text{ K}} = \frac{1}{678\text{ K}}$$
$$= 1.475 \times 10^{-3}\text{ K}^{-1}$$

We are carrying extra "significant figures" for the purpose of graphing the data. The remaining conversions give the table in the margin. Then we plot ln *k* versus $1/T$ as shown in the following figure:

ln *k*	$1/T$ (K^{-1})
2.05	1.475×10^{-3}
2.29	1.453×10^{-3}
2.64	1.433×10^{-3}
2.89	1.412×10^{-3}
3.18	1.393×10^{-3}



The slope of the curve is obtained as the ratio

$$\text{slope} = \frac{\Delta(\ln k)}{\Delta(1/T)}$$
$$= \frac{-0.72}{5.2 \times 10^{-5}\text{ K}^{-1}}$$
$$= -1.4 \times 10^{4}\text{ K} = -E_a/R$$

After changing signs and solving for E_a we have

$$E_a = (8.314\text{ J mol}^{-1}\ \cancel{\text{K}^{-1}})(1.4 \times 10^{4}\ \cancel{\text{K}})$$
$$= 1.2 \times 105\text{ J mol}^{-1}$$
$$= 1.2 \times 102\text{ kJ mol}^{-1}$$

Is the Answer Reasonable? Activation energies must always have a positive sign, and our result is positive. In addition, a check of the units shows that they cancel to give us the correct kJ mol^{-1}. We could try a different pair of points on the same graph to check our work.

Calculating Activation Energies from Rate Constants at Two Temperatures

If the activation energy and the rate constant at a particular temperature are known, the rate constant at another temperature can be calculated using the following relationship, which can be derived from Equation 14.14:

TOOLS

Arrhenius equation, alternate form

$$\ln\left(\frac{k_2}{k_1}\right) = \frac{-E_a}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right) \tag{14.15}$$

This equation can also be used to calculate the activation energy from rate constants measured at two different temperatures. However, the graphical method discussed previously gives more precise values of E_a since more data points are used to plot the graph.

Example 14.13
Calculating the Rate Constant at a Particular Temperature

The reaction $2NO_2 \longrightarrow 2NO + O_2$ has an activation energy of 111 kJ/mol. At 385 °C, $k = 4.9 \text{ L mol}^{-1} \text{ s}^{-1}$. What is the value of k at 465 °C?

Analysis: We know the activation energy and k at one temperature and are asked for the value of k at a second temperature.

Assembling the Tools: We will need to use Equation 14.15 as our tool to obtain k at the other temperature. Since the logarithm term contains the ratio of the rate constants, we will solve for the value of this ratio, substitute the known value of k, and then solve for the unknown k.

Solution: Let's begin by writing Equation 14.15:

$$\ln\left(\frac{k_2}{k_1}\right) = \frac{-E_a}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$

Organizing the data gives us the following table:

	k (L mol^{-1} s^{-1})	T (K)
1	4.9	385 + 273 = 658 K
2	?	465 + 273 = 738 K

We must use $R = 8.314 \text{ J mol}^{-1} \text{ K}^{-1}$ and express E_a in joules ($E_a = 1.11 \times 10^5 \text{ J mol}^{-1}$). Next, we substitute values into the right side of the equation and solve for $\ln(k_2/k_1)$:

$$\ln\left(\frac{k_2}{k_1}\right) = \frac{-1.11 \times 10^5 \ \cancel{\text{J mol}^{-1}}}{8.314 \ \cancel{\text{J mol}^{-1}} \ \text{K}^{-1}}\left(\frac{1}{738 \text{ K}} - \frac{1}{658 \text{ K}}\right)$$

$$= (-1.34 \times 10^4 \ \cancel{\text{K}})(-1.64 \times 10^{-4} \ \cancel{\text{K}^{-1}})$$

Therefore,

$$\ln\left(\frac{k_2}{k_1}\right) = 2.21$$

Taking the antilog gives the ratio of k_2 to k_1:

$$\frac{k_2}{k_1} = e^{2.21} = 9.09$$

Solving for k_2,

$$k_2 = 9.09\ k_1$$

Substituting the value of k_1 from the data table gives

$$k_2 = 9.09(4.9 \text{ L mol}^{-1} \text{ s}^{-1})$$
$$= 45 \text{ L mol}^{-1} \text{ s}^{-1}$$

Is the Answer Reasonable? Although no simple check exists, we have at least found that the value of k for the higher temperature is greater than it is for the lower temperature, as it should be.

Practice Exercises

14.26 | The rate constant is directly proportional to the reaction rate if the same reactant concentrations are used. When determining the stability of a consumer product, less than 5% should decompose in two years at 25 °C. What temperature should we set our oven to if we want to see that same 5% decomposition in one week? Assume the activation energy was previously determined to be 154 kJ mol^{-1}. (*Hint:* All of the information is here to solve the Arrhenius equation.)

14.27 | The reaction $CH_3I + HI \longrightarrow CH_4 + I_2$ was observed to have rate constants $k = 3.2 \text{ L mol}^{-1} \text{ s}^{-1}$ at 355 °C and $k = 23 \text{ L mol}^{-1} \text{ s}^{-1}$ at 405 °C. (a) What is the value of E_a expressed in kJ/mol? (b) What would be the rate constant at 310 °C?

14.28 | Ozone decomposes to form oxygen molecules and oxygen atoms, $O_3(g) \longrightarrow O_2(g) + O(g)$, in the upper atmosphere. The energy of activation for this reaction is 93.1 kJ/mol. At 600 K, the rate constant for this reaction is $3.37 \times 10^3 \, M^{-1} \text{ s}^{-1}$. At what temperature will the rate constant be ten times larger, or $3.37 \times 10^4 \, M^{-1} \text{ s}^{-1}$?

Analyzing and Solving Multi-Concept Problems

A pressure cooker decreases the amount of time it takes to cook food. It does so by sealing the pot and using the water vapor to increase the pressure in the pot; this, in turn, increases the temperature at which water boils (see the vapor pressure graph of water in Chapter 12, page 545). Because cooking involves chemical processes, food cooks faster at higher temperatures. Often, the pressure inside a pressure cooker increases to 2.0 atm. How long will it take to cook 1.0 pound of beans in a pressure cooker if it takes 55 minutes to cook them in boiling water at 1 atm? The pressure in the unsealed pot is 1.0 atm and the boiling point is 100 °C. We will assume that we are using a 4.0 liter pot and that the number of moles of gas in the pot increases from 0.13 mol to 0.25 mol, and that $E_a = 1.77 \times 10^5 \text{ J mol}^{-1} \text{ K}^{-1}$. In addition, since the cooking occurs in the liquid and the beans are covered in water, the reactant concentrations will not change, so the rate constant is directly proportional to the reaction rate.

Analysis We are asked for the amount of time it takes to cook 1.0 pound of beans in a pressure cooker at a higher temperature than at the normal boiling point of water. Since we are looking for a rate that is related to temperature, we can use the Arrhenius equation. We need to decide which form of the Arrhenius equation to use. We are given a time for cooking, 55 min/lb, but that is not a rate or a rate constant, so we will have to convert it into a rate and use the fact that the reaction rates are directly proportional to the rate constants, since the concentrations of the reactions are not changing. We also have the temperature, 100 °C for the unpressurized reaction, as well as the activation energy for the process, so we can use Equation 14.15 to find the rate at the higher temperature. In place of the ratio of the rate constants, we can use the rates, because they are directly proportional to each other.

Unfortunately, we are not given the higher temperature, so we will need to calculate it first. We are given a volume and the number of moles of gas, which leads us to the ideal gas law. Using the ideal gas law, $PV = nRT$, we can calculate the temperature of the gas at the higher pressure.

Now, we have one rate, the two temperatures, and the energy of activation. We can find the other rate. The three steps that we will have to carry out are (1) finding the temperature of the pressure cooker, (2) determining the rate of the reaction under atmospheric pressure, and (3) finding the rate of cooking at the higher temperature using the Arrhenius equation and then determining how long it will take to cook the beans.

PART 1

Assembling the Tools We will use the ideal gas law ($PV = nRT$) as our first tool to find the temperature of the pressure cooker.

Solution Let us start by assembling the data we will need:

Pressure: $P = 2.0$ atm Volume: $V = 4.0$ L
Number of moles: $n = 0.25$ mol Gas constant: $R = 0.0821$ L atm mol^{-1} K^{-1}

Now we can rearrange the equation to see how temperature is related to the rest of the equation:

$$\begin{aligned} PV &= nRT \\ T &= \frac{PV}{nR} \end{aligned}$$

We can substitute these values into the equation to arrive at the higher temperature:

$$\begin{aligned} T &= \frac{(2.0\ \cancel{\text{atm}})(4.0\ \cancel{\text{L}})}{(0.25\ \cancel{\text{mol}})(0.0821\ \cancel{\text{L}}\ \ \cancel{\text{atm}}\ \ \cancel{\text{mol}^{-1}}\ \text{K}^{-1})} \\ T &= 390\ \text{K} \end{aligned}$$

PART 2

Assembling the Tools We have the amount of time to cook the beans at 100 °C, 55 min/lb, and we need to have a rate for that. If we take the inverse of the time, we will get the amount cooked per minute.

Solution

$$\begin{aligned} \text{rate} &= \frac{1.0\ \text{lb}}{55\ \text{min}} \\ \text{rate} &= 0.0182\ \text{lb min}^{-1} \end{aligned}$$

PART 3

Assembling the Tools We have the two temperatures, the rate for the slow reaction, and the energy of activation. For this step, the tool we can use is the Arrhenius equation, Equation 14.15:

$$\ln\left(\frac{k_2}{k_1}\right) = \frac{-E_a}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$

Solution We can have k_2 as the rate we are looking for, and set up the rest of the data as follows:

$E_a = 1.77 \times 10^5\ \text{J mol}^{-1}$
$R = 0.0821\ \text{L atm mol}^{-1}\ \text{K}^{-1}$
$T_1 = 373\ \text{K}$ $\text{rate}_1 = 0.0182\ \text{lb/min}$
$T_2 = 390\ \text{K}$ $\text{rate}_2 = ?$

Substituting these values into the equation gives us

$$\begin{aligned}
\ln \frac{\text{rate}_2}{0.0182 \text{ lb/min}} &= -\left(\frac{1.77 \times 10^5 \cancel{\text{J}}\ \cancel{\text{mol}^{-1}}}{8.314 \cancel{\text{J}}\ \cancel{\text{mol}^{-1}}\ \text{K}^{-1}}\right)\left(\frac{1}{390 \text{ K}} - \frac{1}{373 \text{ K}}\right) \\
\ln \frac{\text{rate}_2}{0.0182 \text{ lb/min}} &= -(1.64 \times 10^5 \text{K})(2.56 \times 10^{-3} \text{ K}^{-1} - 2.68 \times 10^{-3} \text{ K}^{-1}) \\
\ln \frac{\text{rate}_2}{0.0182 \text{ lb/min}} &= -(1.64 \times 10^5 \cancel{\text{K}})(-1.17 \times 10^{-4} \cancel{\text{K}^{-1}}) \\
\ln \frac{\text{rate}_2}{0.0182 \text{ lb/min}} &= 2.49 \\
\frac{\text{rate}_2}{0.0182 \text{ lb/min}} &= e^{2.49} \\
\frac{\text{rate}_2}{0.0182 \text{ lb/min}} &= 12 \\
\text{rate}_2 &= 0.22 \text{ lb/min}
\end{aligned}$$

Finally, we want to know how many minutes it takes to cook 1.0 lb of beans in the pressure cooker, so we need to take the inverse of the value for rate_2 and multiply by 1.0 lb:

$$\text{time} = \frac{1 \text{ min}}{0.22 \text{ lb}} \times 1.0 \text{ lb}$$

$$\text{time} = 4.5 \text{ min, or about 5 minutes}$$

■ **Are the Answers Reasonable?** One check is to look at the reasoning. Does the rate of the reaction go up if the temperature goes up? Another way to ask the question is: Does the time it takes to cook the beans go down? Both answers are "yes," so we are on the right track. Next, is the amount of time reasonable? Five minutes to cook something is reasonable, as long as the temperature is high enough.

14.8 | Mechanisms of Reactions

A balanced equation generally describes only a net overall change. Usually, however, the net change is the result of a series of simple reactions that are not at all evident from the equation. Consider, for example, the combustion of propane, C_3H_8:

$$C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(g)$$

Anyone who has ever played billiards knows that this reaction simply cannot occur in a single, simultaneous collision between one propane molecule and five oxygen molecules. Just getting only three balls to come together with but one "click" on a flat, two-dimensional surface is extremely improbable. How unlikely it must be, then, for the *simultaneous* collision in three-dimensional space of six reactant molecules, one of which must be C_3H_8 and the other five O_2. Instead, the combustion of propane proceeds very rapidly by a series of much more probable steps. *The series of individual steps that add up to the overall observed reaction is called the* **reaction mechanism**. Information about reaction mechanisms is one of the dividends paid by the study of reaction rates.

Each individual step in a reaction mechanism is a simple chemical reaction called an *elementary process*. An **elementary process** is a reaction involving collisions between molecules. As you will soon see, a rate law can be written from the equation for an elementary process, using coefficients as exponents for the concentration terms without requiring experiments to determine the exponents. For most reactions, the individual elementary processes cannot actually be observed because they involve substances of fleeting existence; instead, we only see the net reaction. Therefore, the mechanism a chemist writes is really a *theory* about what occurs step-by-step as the reactants are changed to the products.

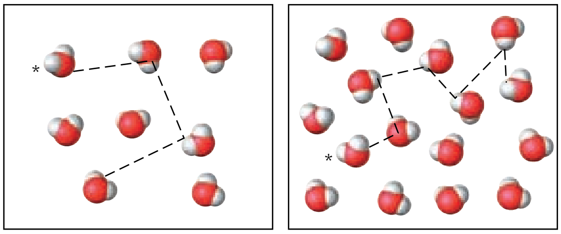
Because the individual steps in a mechanism usually cannot be observed directly, devising a mechanism for a reaction requires some ingenuity. However, we can immediately tell whether a proposed mechanism is feasible, because *the rate law derived from the mechanism must agree with the experimental rate law for the reaction.*

Elementary Processes

Consider the following elementary process that involves collisions between two identical molecules, leading directly to the products shown:

$$2NO_2 \longrightarrow NO_3 + NO \qquad \textbf{(14.16)}$$

$$\text{Rate} = k\,[NO_2]^x$$



t = 1s *t* = 1s

Figure 14.17 | **The relative number of collisions in a given amount of time.** For the molecule marked with an asterisk, *, the number of collisions in a given amount of time doubles when the concentration doubles. Since there are now twice as many molecules, each one has twice as many collisions.

How can we predict the value of the exponent, *x*? Suppose the NO_2 concentration were doubled. There would now be *twice* as many NO_2 molecules and *each* would have *twice* as many neighbors with which to collide (Figure 14.17). The number of NO_2-to-NO_2 collisions per second would doubly double—in other words, increase by a factor of 4. This would cause the rate to increase by a factor of 4, which is 2^2. Earlier we saw that when doubling a concentration leads to a four-fold increase in the rate, the concentration of that reactant is raised to the second power in the rate law. Thus, if Equation 14.16 represents an elementary process, its rate law should be

$$\text{rate} = k\,[NO_2]^2$$

Notice that the exponent in the rate law for this elementary process is the same as the coefficient in the chemical equation. Similar analyses for other types of elementary processes lead to similar observations and the following statement:

TOOLS

Rate laws for elementary processes

> The exponents in the rate law for an elementary process are equal to the coefficients of the reactants in the chemical equation for that elementary process.

Remember that this rule applies only to *elementary processes*. If all we know is the balanced chemical equation for the overall reaction, the only way we can find the exponents of the rate law is by doing experiments.

Rate Laws and Rate-Determining Steps

How does the ability to predict the rate law of an elementary process help chemists predict reaction mechanisms? To answer this question, let's look at two reactions and what are believed to be their mechanisms. (There are many other, more complicated systems, and *Chemistry Outside the Classroom 14.1* describes one type, the free radical chain reaction, that is particularly important.) Let's consider two ways in which mechanisms and experimental rate laws are used.

First Case: First Step as the Rate-Determining Step

First, consider the gaseous reaction,

$$2NO_2Cl \longrightarrow 2NO_2 + Cl_2 \qquad \textbf{(14.17)}$$

Experimentally, the rate is first order in NO_2Cl, so the rate law is

$$\text{rate} = k\,[NO_2Cl] \qquad (\textit{experimental})$$

The first question we might ask is, Could the overall reaction (Equation 14.17) occur in a single step by the collision of two NO_2Cl molecules? The answer is "no," because then it would be an elementary process and the rate law predicted for it would include a squared term, $[NO_2Cl]^2$. Instead, the experimental rate law is first order in NO_2Cl. Thus, the predicted and experimental rate laws don't agree, so we must look further to find the mechanism of the reaction.

CHEMISTRY OUTSIDE THE CLASSROOM 14.1

Free Radicals, Explosions, Octane Ratings, and Aging

A **free radical** is a very reactive species that contains one or more unpaired electrons. Examples are chlorine atoms formed when a Cl_2 molecule absorbs a photon (light) of the appropriate energy:

$$Cl_2 + \text{light energy } (h\nu) \longrightarrow 2Cl\cdot$$

(A dot placed next to the symbol of an atom or molecule represents an unpaired electron and indicates that the particle is a free radical.) The reason free radicals are so reactive is because of the tendency of electrons to become paired through the formation of either ions or covalent bonds.

Free radicals are important in many gaseous reactions, including those responsible for the production of photochemical smog in urban areas. Reactions involving free radicals have useful applications, too. For example, many plastics are made by reactions that take place by mechanisms that involve free radicals. In addition, free radicals play a part in *thermal cracking*, one of the most important processes in the petroleum industry. This reaction is used to break C—C and C—H bonds in long-chain hydrocarbons to produce the smaller molecules that give gasoline a higher octane rating. An example is the formation of free radicals in the thermal cracking reaction of butane. When butane is heated to 700–800 °C, one of the major reactions that occurs is

$$CH_3—CH_2:CH_2—CH_3 \xrightarrow{\text{heat}} CH_3CH_2\cdot + CH_3CH_2\cdot$$

The central C—C bond of butane is shown here as a pair of dots, **:**, rather than the usual dash. When the bond is broken, the electron pair is divided between the two free radicals that are formed. This reaction produces two ethyl radicals, $CH_3CH_2\cdot$.

Free radical reactions tend to have high initial activation energies because chemical bonds must be broken to form the radicals. Once the free radicals are formed, however, reactions in which they are involved tend to be very rapid.

Free Radical Chain Reactions

In many cases, a free radical reacts with a reactant molecule to give a product molecule plus another free radical. Reactions that involve such a step are called **chain reactions**.

Many explosive reactions are chain reactions involving free radical mechanisms. One of the most studied reactions of this type is the formation of water from hydrogen and oxygen. The elementary processes involved can be described according to their roles in the mechanism.

The reaction begins with an **initiation step** that gives free radicals:

$$H_2 + O_2 \xrightarrow{\text{hot surface}} 2OH\cdot \qquad \text{(initiation)}$$

The chain continues with a **propagation step**, which produces the product plus another free radical.

$$OH\cdot + H_2 \longrightarrow H_2O + H\cdot \qquad \text{(propagation)}$$

The reaction of H_2 and O_2 is explosive because the mechanism also contains **branching steps**:

$$\left.\begin{array}{l} H\cdot + O_2 \longrightarrow OH\cdot + O\cdot \\ O\cdot + H_2 \longrightarrow OH\cdot + H\cdot \end{array}\right] \quad \text{(branching)}$$

Thus, the reaction of one H· with O_2 leads to the net production of two OH· plus an O·. Every time an H· reacts with oxygen, then, there is an increase in the number of free radicals in the system. The free radical concentration grows rapidly, and the reaction rate becomes explosively fast.

Chain mechanisms also contain **termination steps**, which remove free radicals from the system. In the reaction of H_2 and O_2, the wall of the reaction vessel serves to remove H·, which tends to halt the chain process.

$$2H\cdot \xrightarrow{\text{wall}} H_2$$

Free Radicals and Aging

Direct experimental evidence also exists for the presence of free radicals in functioning biological systems. These highly reactive species play many roles, but one of the most interesting is their apparent involvement in the aging process. One theory suggests that free radicals attack protein molecules in collagen. Collagen is composed of long strands of proteins and is found throughout the body, especially in the flexible tissues of the lungs, skin, muscles, and blood vessels. Attack by free radicals seems to lead to cross-linking between these fibers, which makes them less flexible. The most readily observable result of this is the stiffening and hardening of the skin that accompanies aging or too much sunbathing (see Figure 1).

Free radicals also seem to affect fats (lipids) within the body by promoting the oxidation and deactivation of enzymes that are normally involved in the metabolism of lipids. Over a long period, the accumulated damage gradually reduces the efficiency with which the cell carries out its activities. Interestingly, vitamin E appears to be a natural free radical inhibitor. Diets that are deficient in vitamin E produce effects resembling radiation damage and aging.

Still another theory of aging suggests that free radicals attack the DNA in the nuclei of cells. DNA is the substance that is responsible for directing the chemical activities required for the successful functioning of the cell. Reactions with free radicals cause a gradual accumulation of errors in the DNA, which reduce the efficiency of the cell and can lead, ultimately, to malfunction and cell death.

Figure 1 People exposed to sunlight over long periods, like this woman from Nepal (a small country between India and Tibet), tend to develop wrinkles because ultraviolet radiation causes changes in their skin. *(Franck Guiziou/Hemis/© Corbis)*

■ The Cl atom formed here is called a *reactive intermediate*. We never actually observe the Cl because it reacts so quickly.

On the basis of chemical intuition and other information that we won't discuss here, chemists believe the actual mechanism of the reaction in Equation 14.17 is the following two-step sequence of elementary processes:

$$\mathrm{NO_2Cl} \longrightarrow \mathrm{NO_2 + Cl}$$
$$\mathrm{NO_2Cl + Cl} \longrightarrow \mathrm{NO_2 + Cl_2}$$

Notice that when the two reactions are added, the *intermediate*, Cl, drops out and we obtain the net overall reaction given in Equation 14.17. *Being able to add the elementary processes and thus to obtain the overall reaction is another major test of a mechanism.*

In any multi-step mechanism, one step is usually much slower than the others. In this mechanism, for example, it is believed that the first step is slow and that once a Cl atom forms, it reacts very rapidly with another NO_2Cl molecule to give the final products.

The final products of a multi-step reaction cannot appear faster than the products of the slow step, so the slow step in a mechanism is called the **rate-determining step** or the **rate-limiting step**. In the preceding two-step mechanism, then, the first reaction is the rate-determining step because the final products can't be formed faster than the rate at which Cl atoms form.

The rate-determining step is similar to a slow worker on an assembly line. The production rate depends on how quickly the slow worker works, regardless of how fast the other workers are. The factors that control the speed of the rate-determining step, therefore, also control the overall rate of the reaction. This means that *the rate law for the rate-determining step is directly related to the rate law for the overall reaction.*

Because the rate-determining step is an elementary process, we can predict its rate law from the coefficients of its reactants. The coefficient of NO_2Cl in its relatively slow breakdown to NO_2 and Cl is 1. Therefore, the rate law predicted for the first step is

$$\text{rate} = k\,[\mathrm{NO_2Cl}] \qquad (\textit{predicted})$$

Thus, the predicted rate law derived for the two-step mechanism agrees with the experimentally measured rate law. Although this doesn't *prove* that the mechanism is correct, it does provide considerable support for it. From the standpoint of kinetics, therefore, the mechanism is reasonable.

Second Case: Second Step as the Rate-Determining Step

The second reaction mechanism that we will study is that of the following gas phase reaction:

$$\mathrm{2NO + 2H_2} \longrightarrow \mathrm{N_2 + 2H_2O} \qquad \textbf{(14.18)}$$

The experimentally determined rate law is

$$\text{rate} = k\,[\mathrm{NO}]^2\,[\mathrm{H_2}] \qquad (\textit{experimental})$$

Based on this rate law, Equation 14.18 could *not* itself be an elementary process. If it were, the exponent for $[H_2]$ would have to be 2. Instead, a mechanism involving two or more steps must be involved.

A chemically reasonable mechanism that yields the correct form for the rate law consists of the following two steps:

$$\mathrm{2NO + H_2} \longrightarrow \mathrm{N_2O + H_2O} \qquad \text{(slow)}$$
$$\mathrm{N_2O + H_2} \longrightarrow \mathrm{N_2 + H_2O} \qquad \text{(fast)}$$

One test of the mechanism, as we said, is that the two equations must add to give the correct overall equation; and they do. Furthermore, the chemistry of the second step has actually been observed in separate experiments. N_2O is a known compound, and it does react with H_2 to give N_2 and H_2O. Another test of the mechanism involves the coefficients of NO and H_2 in the predicted rate law for the first step, the supposed rate-determining step:

$$\text{rate} = k\,[\mathrm{NO}]^2\,[\mathrm{H_2}] \qquad (\textit{predicted})$$

This rate equation does match the experimental rate law, but there is still a serious flaw in the proposed mechanism. If the postulated slow step actually described an elementary process, it would involve the simultaneous collision between three molecules, two NO and one H_2. A three-way collision is so unlikely that if it were really involved in the mechanism, the overall reaction would be extremely slow. Reaction mechanisms seldom include elementary processes that involve more than two-body or **bimolecular collisions.**

Chemists believe the reaction in Equation 14.18 proceeds by the following three-step sequence of bimolecular elementary processes:

$$\begin{aligned} 2NO &\rightleftharpoons N_2O_2 && \text{(fast)} \\ N_2O_2 + H_2 &\longrightarrow N_2O + H_2O && \text{(slow)} \\ N_2O + H_2 &\longrightarrow N_2 + H_2O && \text{(fast)} \end{aligned}$$

In this mechanism, the first step is proposed to be a rapidly established equilibrium in which the unstable intermediate N_2O_2 forms in the forward reaction and then quickly decomposes into NO by the reverse reaction. The rate-determining step is the reaction of N_2O_2 with H_2 to give N_2O and a water molecule. The third step is the reaction mentioned above. Once again, notice that the three steps add to give the net overall change.

Since the second step is rate determining, the rate law for the reaction should match the rate law for this step. We predict this to be

$$\text{rate} = k\,[N_2O_2]\,[H_2] \qquad \textbf{(14.19)}$$

■ The occurrence of N_2O_2 as an intermediate in the proposed mechanism can only be surmised. The compound is never present at a detectable concentration because it's too unstable.

However, the experimental rate law does not contain the species N_2O_2. Therefore, we must find a way to express the concentration of N_2O_2 in terms of the reactants in the overall reaction. To do this, let's look closely at the first step of the mechanism, which we view as a reversible reaction.

The rate in the forward direction, in which NO is the reactant, is

$$\text{rate (forward)} = k_f\,[NO]^2$$

The rate of the reverse reaction, in which N_2O_2 is the reactant, is

$$\text{rate (reverse)} = k_r\,[N_2O_2]$$

If we view this as a dynamic equilibrium, then the rate of the forward and reverse reactions are equal, which means that

$$k_f\,[NO]^2 = k_r\,[N_2O_2] \qquad \textbf{(14.20)}$$

■ Recall that in a dynamic equilibrium, forward and reverse reactions occur at equal rates.

Since we would like to eliminate N_2O_2 from the rate law in Equation 14.19, let's solve Equation 14.20 for $[N_2O_2]$:

$$[N_2O_2] = \frac{k_f}{k_r}[NO]^2$$

Substituting into the rate law in Equation 14.19 yields

$$\text{rate} = k\left(\frac{k_f}{k_r}\right)[NO]^2[H_2]$$

Combining all of the constants into one (k') gives

$$\text{rate} = k'\,[NO]^2\,[H_2] \qquad (\textit{predicted})$$

Now, the rate law derived from the mechanism matches the rate law obtained experimentally. The three-step mechanism does appear to be reasonable on the basis of kinetics.

The procedure we have worked through here applies to many reactions that proceed by mechanisms involving sequential steps. Steps that precede the rate-determining step are considered to be rapidly established equilibria involving unstable intermediates.

■ There are many reactions that do not follow simple first- or second-order rate laws and have mechanisms far more complex than those studied in this section. Even so, their more complex kinetics still serve as clues to their complex set of elementary processes.

Relating the Proposed Mechanism to the Experimental Rate Law

Although chemists may devise other experiments to help prove or disprove the correctness of a mechanism, one of the strongest pieces of evidence is the experimentally measured rate law for the overall reaction. No matter how reasonable a particular mechanism may appear, if its elementary processes cannot yield a predicted rate law that matches the experimental one, the mechanism is wrong and must be discarded.

In some cases the experimental rate law may suggest two different but equally probable mechanisms. One method for testing mechanisms is to find evidence of unique intermediates. In the previous mechanisms, both had N_2O as an intermediate, but the second mechanism had N_2O_2 as a unique intermediate. If experiments could show the existence of N_2O_2 during the reaction, the second mechanism would have added evidence that it is the correct mechanism.

Practice Exercises

14.29 | Select the reactions below that may be elementary processes. For those not selected, explain why they are not elementary processes.

(a) $2N_2O_5 \longrightarrow 2N_2O_4 + O_2$

(b) $NO + O_3 \longrightarrow NO_2 + O_2$

(c) $2NO + H_2 \longrightarrow N_2O + H_2O$

(d) $C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(g)$

(e) $C_{12}H_{22}O_{11} + H_2O \longrightarrow C_6H_{12}O_6 + C_6H_{12}O_6$

(f) $3H_2 + N_2 \longrightarrow 2NH_3$

(*Hint:* How many molecules are likely to collide at exactly the same time?)

14.30 | Ozone, O_3, reacts with nitric oxide, NO, to form nitrogen dioxide and oxygen:

$$NO + O_3 \longrightarrow NO_2 + O_2$$

This is one of the reactions involved in the formation of photochemical smog. If this reaction occurs in a single step, what is the expected rate law for the reaction?

14.31 | The mechanism for the decomposition of NO_2Cl is

$$NO_2Cl \rightleftharpoons NO_2 + Cl$$
$$NO_2Cl + Cl \longrightarrow NO_2 + Cl_2$$

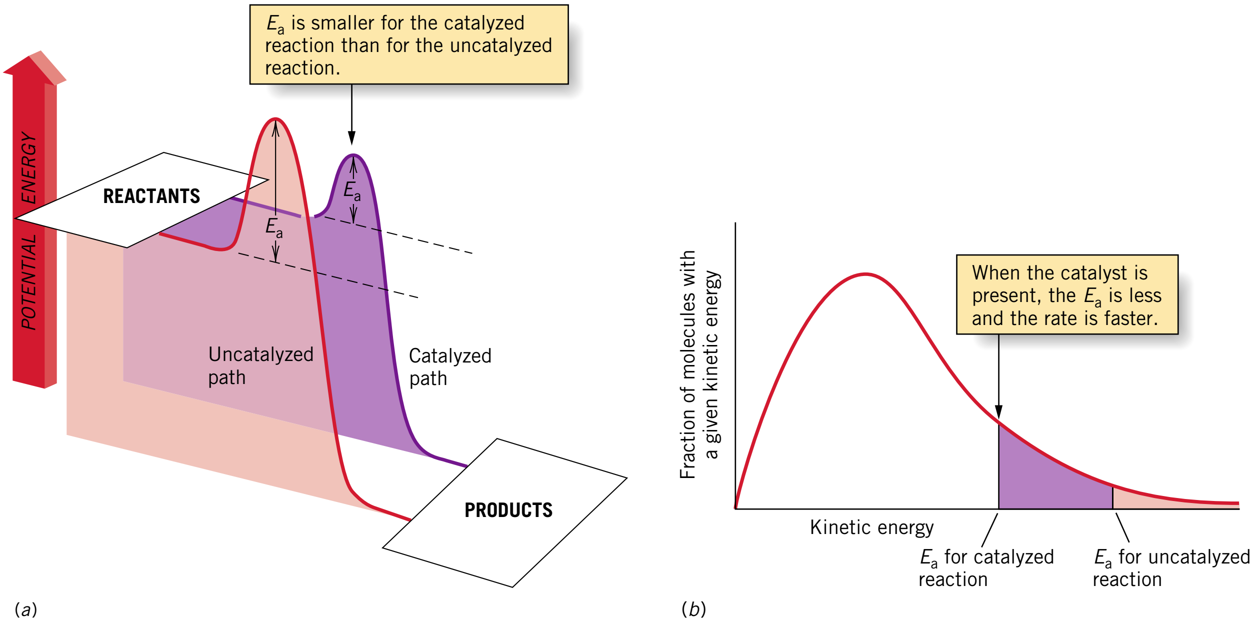
What would the predicted rate law be if the second step in the mechanism were the rate-determining step?

14.9 | Catalysts

A **catalyst** is a substance that changes the rate of a chemical reaction without itself being used up. In other words, all of the catalyst added at the start of a reaction is present chemically unchanged after the reaction has gone to completion. The action caused by a catalyst is called **catalysis.** Broadly speaking, there are two kinds of catalysts. *Positive catalysts* speed up reactions, whereas *negative catalysts*, usually called *inhibitors,* slow reactions down. After this, when we use "catalyst" we'll mean positive catalyst, the usual connotation.

Although the catalyst is not part of the overall reaction, it does participate by changing the mechanism of the reaction. The catalyst provides a path to the products that has a rate-determining step with a lower activation energy than that of the uncatalyzed reaction (see Figure 14.18). Because the activation energy along this new route is lower, a greater fraction of the collisions of the reactant molecules have the minimum energy needed to react, so the reaction proceeds faster.

Catalysts can be divided into two groups—**homogeneous catalysts**, which exist in the same phase as the reactants, and **heterogeneous catalysts**, which exist in a separate phase from the reactants.



E_a is smaller for the catalyzed reaction than for the uncatalyzed reaction.

When the catalyst is present, the E_a is less and the rate is faster.

(b)

Figure 14.18 | **The effect of a catalyst on a reaction.** (*a*) The catalyst provides an alternative, low-energy path from the reactants to the products. (*b*) A larger fraction of molecules have sufficient energy to react when the catalyzed path is available.

Homogeneous Catalysts

An example of homogeneous catalysis is found in the now outdated *lead chamber process* for manufacturing sulfuric acid. To make sulfuric acid by this process, sulfur is burned to give SO_2, which is then oxidized to SO_3. The SO_3 is dissolved in water as it forms to give H_2SO_4.

■ In the modern process for making sulfuric acid, the contact process, vanadium(V) oxide, V_2O_5, is a heterogeneous catalyst that promotes the oxidation of sulfur dioxide to sulfur trioxide.

$$\begin{aligned} S + O_2 &\longrightarrow SO_2 \\ SO_2 + \tfrac{1}{2}O_2 &\longrightarrow SO_3 \\ SO_3 + H_2O &\longrightarrow H_2SO_4 \end{aligned}$$

Unassisted, the second reaction, the oxidation of SO_2 to SO_3, occurs slowly. In the lead chamber process, the SO_2 is combined with a mixture of NO, NO_2, air, and steam in large, lead-lined reaction chambers. The NO_2 readily oxidizes the SO_2 to give NO and SO_3. The NO is then reoxidized to NO_2 by oxygen.

■ The NO_2 is regenerated in the second reaction and so is recycled over and over. Thus, only small amounts of it are needed in the reaction mixture to do an effective catalytic job.

$$\begin{aligned} NO_2 + SO_2 &\longrightarrow NO + SO_3 \\ NO + \tfrac{1}{2}O_2 &\longrightarrow NO_2 \end{aligned}$$

The NO_2 serves as a catalyst by being an oxygen carrier and by providing a low-energy path for the oxidation of SO_2 to SO_3. Notice that the NO_2 is regenerated; it has not been permanently changed, a necessary condition for any catalyst.

Heterogeneous Catalysts

A heterogeneous catalyst is commonly a solid, and it usually functions by promoting a reaction on its surface. One or more of the reactant molecules are adsorbed onto the surface of the catalyst, where an interaction with the surface increases their reactivity. An example is the synthesis of ammonia from hydrogen and nitrogen by the Haber process.

■ **Adsorption** means that molecules bind to a surface.

$$3H_2 + N_2 \longrightarrow 2NH_3$$

H
N
N
Molecules of H_2 and N_2 dissociate into atoms.
Bonds from H to N begin to form.
Bond formation continues.
Ammonia molecules have formed.
Ammonia molecules leave the catalyst's surface.

Figure 14.19 | **The Haber process.** Catalytic formation of ammonia molecules from hydrogen and nitrogen on the surface of a catalyst.

The reaction takes place on the surface of an iron catalyst that contains traces of aluminum and potassium oxides. It is thought that hydrogen molecules and nitrogen molecules dissociate while being held on the catalytic surface. The hydrogen atoms then combine with the nitrogen atoms to form ammonia. Finally, the completed ammonia molecule breaks away, freeing the surface of the catalyst for further reaction. This sequence of steps is illustrated in Figure 14.19.

Heterogeneous catalysts are used in many important commercial processes. The petroleum industry uses heterogeneous catalysts to crack hydrocarbons into smaller fragments and then re-form them into the useful components of gasoline (see Figure 14.20). The availability of such catalysts allows refineries to produce gasoline, jet fuel, or heating oil from crude oil in any ratio necessary to meet the demands of the marketplace.

A vehicle that uses unleaded gasoline is equipped with a catalytic converter (Figure 14.21) designed to lower the concentrations of exhaust gas pollutants, such as carbon monoxide, unburned hydrocarbons, and nitrogen oxides. The catalysts are nanometer-sized particles of platinum, ruthenium, and rhodium dispersed in a honeycomb of a high-temperature ceramic. The large ratio of surface area to mass enables the catalytic converter to react with

(*a*) (*b*)

Figure 14.20 | **Catalysts are very important in the petroleum industry.** (*a*) Catalytic cracking towers at an oil refinery. (*b*) A variety of catalysts are available as beads, powders, or in other forms for various refinery operations. *(a: Wes Thompson/© Corbis; b: BASF Corporation)* large volumes of exhaust efficiently. Air is introduced into the exhaust stream that then passes over a catalyst that adsorbs CO, NO, and O_2. The NO dissociates into N and O atoms, and the O_2 also dissociates into atoms. Pairing of nitrogen atoms then produces N_2, and the oxidation of CO by oxygen atoms produces CO_2. Unburned hydrocarbons are also oxidized to CO_2 and H_2O. The catalysts in catalytic converters are deactivated or "poisoned" by lead-based octane boosters like tetraethyl lead $[Pb(C_2H_5)_4]$. Leaded gasoline was finally banned in 1995. Leaded gasoline also posed an environmental hazard from the lead emitted in automobile exhaust.

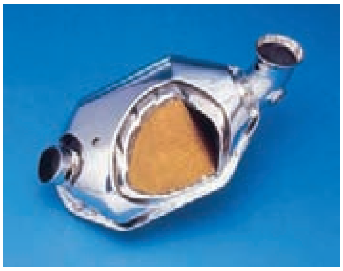

Figure 14.21 | **A modern catalytic converter of the type used in about 80% of new cars.** Part of the converter has been cut away to reveal the porous ceramic material that serves as the support for the catalyst. *(Courtesy BASF Corporation)*

The poisoning of catalysts is also a major problem in many industrial processes. Methyl alcohol (methanol, CH_3OH), for example, is a promising fuel that can be made from coal and steam by the reaction

$$\text{C (from coal)} + H_2O \longrightarrow CO + H_2$$

followed by

$$CO + 2H_2 \longrightarrow CH_3OH$$

A catalyst for the second step is copper(I) ion held in solid solution with zinc oxide. However, traces of sulfur, a contaminant in coal, must be avoided because sulfur reacts with the catalyst and destroys its catalytic activity.

Enzymes

In living systems, complex protein-based molecules called *enzymes* catalyze almost every reaction that occurs in living cells. Enzymes contain a specially shaped area called an "active site" that lowers the energy of the transition state of the reaction being catalyzed. This causes the reaction rate to increase significantly. Many poisons have been shown to work by blocking important enzyme systems. Heavy metals bind to sulfur-containing groups and distort the active site. Many modern drugs work by inhibiting the catalytic activity of specific enzymes in the human body. In the pharmaceutical industry, chemists use molecular modeling to design drug molecules that have optimum shapes to fit enzymatic active sites. The better the fit, the more potent the drug will be.

Summary

Reaction Rates. The speeds or **rates** of reactions are controlled by five factors: (1) the nature of the reactants, (2) the ability of the reactants to meet, (3) the concentrations of the reactants, (4) the temperature, and (5) the presence of catalysts. The rates of **heterogeneous reactions** are determined largely by the area of contact between the phases; the rates of **homogeneous reactions** are determined by the concentrations of the reactants. The rate is measured by monitoring the change in reactant or product concentrations with time:

$$\text{Rate} = \Delta(\text{concentration})/\Delta(\text{time})$$

In any chemical reaction, the rates of formation of products and the rates of disappearance of reactants are related by the coefficients of the balanced overall chemical equation.

Rate Laws. The **rate law** for a reaction relates the reaction rate to the molar concentrations of the reactants. The rate is proportional to the product of the molar concentrations of the reactants, each raised to an appropriate power. These exponents must be determined by experiments in which the concentrations are varied and the effects of the variations on the rate are measured. The proportionality constant, $\boldsymbol{k}$, is called the **rate constant**. Its value depends on temperature but not on the concentrations of the reactants. The sum of the exponents in the rate law is the **order** (or overall order) of the reaction.

Concentration and Time. Equations exist that relate the concentration of a reactant at a given time t to the initial concentration and the rate constant. The time required for half of a reactant to disappear is the **half-life**, $t_{1/2}$. For a first-order reaction, the half-life is a constant that depends only on the rate constant for the reaction; it is independent of the initial concentration. The half-life for a second-order reaction is inversely proportional both to the initial concentration of the reactant and to the rate constant. The half-life for a zero-order reaction is inversely proportional to the rate constant and proportional to the inital concentration.

Theories of Reaction Rate. According to **collision theory**, the rate of a reaction depends on the number of **effective collisions** per second of the reactant particles, which is only an extremely small fraction of the total number of collisions per second. This fraction is so small partly because the reactant molecules must be suitably oriented, but mostly because the colliding molecules must jointly possess a minimum molecular kinetic energy called the **activation energy**, **E_a**. As the temperature increases, a larger fraction of the collisions has this necessary energy, making more collisions effective each second and the reaction faster.

Transition state theory visualizes how the energies of molecules and the orientations of their nuclei interact as they collide. In this theory, the energy of activation is viewed as an energy barrier on the reaction's potential energy diagram. The *heat of reaction* is the net potential energy difference between the reactants and the products. In reversible reactions, the values of E_a for both the forward and reverse reactions can be identified on an energy diagram. The species at the high point on an energy diagram is the **activated complex** and is said to be in the **transition state**.

Determining the Activation Energy. **The Arrhenius equation** lets us see how changes in activation energy and temperature affect a rate constant. The Arrhenius equation also lets us determine E_a either graphically or by a calculation using the appropriate form of the equation. The calculation requires two rate constants determined at two temperatures. The graphical method uses more values of rate constants at more temperatures and thus usually yields more accurate results. The activation energy and the rate constant at one temperature can be used to calculate the rate constant at another temperature.

Reaction Mechanisms. The detailed sequence of elementary processes that lead to the net chemical change is the **mechanism** of the reaction. Since intermediates usually cannot be detected, the mechanism is a theory. Support for a mechanism comes from matching the predicted rate law for the mechanism with the rate law obtained from experimental data. For the **rate-determining step** or for any **elementary process**, the corresponding rate law has exponents equal to the coefficients in the balanced chemical equation for the elementary process.

Catalysts. **Catalysts** are substances that change a reaction rate but are not used up by the reaction. Negative catalysts inhibit reactions. Positive catalysts provide alternative paths for reactions for which at least one step has a smaller activation energy than the uncatalyzed reaction. **Homogeneous catalysts** are in the same phase as the reactants. **Heterogeneous catalysts** provide a path of lower activation energy by having a surface on which the reactants are adsorbed and react. Catalysts in living systems are called enzymes.

TOOLS

Tools for Problem Solving

The following tools were introduced in this chapter. Study them carefully so you can select the appropriate tool when needed.

Factors that affect reaction rates (page 637)

The five factors that affect the rate of reactions are (1) the chemical nature of the reactants; (2) the ability of the reactants to come in contact with each other; (3) the concentrations of the reactants; (4) the temperature of the reaction; and (5) the availability of catalysts.

Rate with respect to one reactant of product (page 639)

This is the instantaneous rate of the reaction with respect to one reactant or product. It can be determined by measuring the change in concentration versus time for the tangent to the curve of time versus concentration at the given time.

$$\text{Rate} = \frac{\Delta(\text{conc. of } X)}{\Delta t}$$

The rates are always expressed as a positive value, so if the concentration is decreasing for a reactant, the sign is changed to the positive.

Rate of a reaction (page 642)

The rate of a reaction does not change with what is being monitored. Therefore, for the reaction,

$$aA + bB \longrightarrow cC + dD$$

the rate expression is

$$\text{rate} = -\frac{1}{a}\frac{\Delta[A]}{\Delta t} = -\frac{1}{b}\frac{\Delta[B]}{\Delta t} = \frac{1}{c}\frac{\Delta[C]}{\Delta t} = \frac{1}{d}\frac{\Delta[D]}{\Delta t}$$

Rate law of a reaction (page 645)

A rate law allows us to calculate the rate of reaction for a given set of reactant concentrations. It also serves as a guide in devising reasonable reaction mechanisms. Exponents for the concentrations in the rate law are always determined experimentally, as described on page 648. Rate constants determined at different temperatures are used in the Arrhenius equation described below:

$$\text{rate} = k\,[A]^n\,[B]^m$$

Determining the order of reactions (page 648)

In the rate law, the order of the reaction is the sum of the exponents for the concentrations of the reactants. The order of the reaction can only be determined by experiment. Data are obtained from experiments conducted under different sets of conditions. For example, the concentration of one reactant may be changed, then the ratios of the rates to the concentrations are compared:

$$\frac{\text{rate}_2}{\text{rate}_1} = \frac{k[A]_2^{\,n}[B]_2^{\,m}}{k[A]_1^{\,n}[B]_1^{\,m}} = \frac{k}{k}\left(\frac{[A]_2}{[A]_1}\right)^n\left(\frac{[B]_2}{[B]_1}\right)^m$$

Integrated first-order rate law (page 654)

For a first-order reaction with known k, this equation is used when we need to calculate the concentration of a reactant at some specified time after the start of the reaction. We could also calculate the time required for the concentration to drop to some specified value. This equation is also used for the carbon-14 dating of organic materials.

$$\ln\frac{[A]_0}{[A]_t} = kt$$

Half-lives of first-order reactions (page 657)

This equation relates the rate constant to the half-life, $t_{1/2}$, for first-order reactions. Use of half-lives can be a convenient alternative to the integrated first-order rate law to determine the concentration of a reactant after it has reacted for a whole number of half-lives. The amount of reactant left after n half-lives is equal to $\left(\frac{1}{2}\right)^n$.

$$\ln 2 = kt_{1/2}$$

Carbon-14 dating (page 660)

Carbon-14 dating is a special example of a half-life of a first-order reaction. The half-life for carbon-14 is 5730 years and the rate constant is $1.21 \times 10^{-4}\ \text{yr}^{-1}$. The age of an object can be found by comparing the ratio of $^{14}C/^{12}C$, r_t, from an object in question to the ratio of $^{14}C/^{12}C$ in a contemporary sample, r_0.

$$\ln\frac{r_0}{r_t} = (1.21 \times 10^{-4}\ \text{yr}^{-1})t$$

Integrated second-order rate law (page 661)

For a second-order reaction of the form, rate $= k[B]^2$, with known k, this equation is used to calculate the concentration of a reactant at some specified time after the start of the reaction, or the time required for the concentration to decrease to some specified value.

$$\frac{1}{[B]_t} - \frac{1}{[B]_0} = kt$$

Integrated zero-order rate law (page 663)

In a zero-order rate law with the form, rate $= k$, the rate is independent of the concentration of the reactants. The integrated rate law is

$$[A]_t = -kt + [A]_0$$

Arrhenius equation (page 669)

This equation relates the rate constant, k, to the activation energy, E_a, and temperature. Activation energies are determined by measuring rate constants at a variety of temperatures and graphically analyzing the data (see page 671). This equation is also used to determine the shelf life of a wide variety of consumer products.

$$k = A\,e^{-E_a/RT}$$

Arrhenius equation, alternate form (page 672)

The rate constants for a reaction at two different temperatures are related by the alternate form of the Arrhenius equation:

$$\ln\left(\frac{k_2}{k_1}\right) = \frac{-E_a}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$

Rate laws for elementary processes (page 676)

The exponents in the rate laws are equal to the coefficients of the reactants in the chemical equations for that elementary process.

PLUS = *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com.** **ILW** = An Interactive Learningware solution is available for this problem. **OH** = An Office Hour video is available for this problem. Review Problems are presented in pairs separated by blue rules. Answers to problems whose numbers appear in blue are given in Appendix B. More challenging problems are marked with an asterisk *.

Review Questions

Factors that Affect Reaction Rate

14.1 Give an example from everyday experience of **(a)** a very fast reaction, **(b)** a moderately fast reaction, and **(c)** a slow reaction.

14.2 Suppose we compared two reactions, one requiring the simultaneous collision of three molecules and the other requiring a collision between two molecules. From the standpoint of statistics, and all other factors being equal, which reaction should be faster? Explain your answer.

14.3 How does an instantaneous rate of reaction differ from an average rate of reaction?

14.4 Explain how the initial instantaneous rate of reaction can be determined from experimental concentration versus time data.

14.5 What is a *homogeneous reaction*? What is a *heterogeneous reaction*? Give examples.

14.6 Why are chemical reactions usually carried out in solution?

14.7 What is the major factor that affects the rate of a heterogeneous reaction?

14.8 How does particle size affect the rate of a heterogeneous reaction? Why?

14.9 The rate of hardening of epoxy glue depends on the amount of hardener that is mixed into the glue. What factor affecting reaction rates does this illustrate?

14.10 A Polaroid™ instant photograph develops faster if it's kept warm than if it is exposed to cold. Why?

14.11 Insects have no way of controlling their body temperatures like mammals do. In cool weather, they become sluggish and move less quickly. How can this be explained using the principles developed in this chapter?

14.12 Persons who have been submerged in very cold water and who are believed to have drowned sometimes can be revived. On the other hand, persons who have been submerged in warmer water for the same length of time have died. Explain this in terms of factors that affect the rates of chemical reactions.

Concentration and Rate; Rate Laws

14.13 What are the units of reaction rate? What is the sign of a reaction rate?

14.14 What are the units of the rate constant for **(a)** a first-order reaction, **(b)** a second-order reaction, and **(c)** a zero-order reaction?

14.15 How does the dependence of reaction rate on concentration differ between a zero-order and a first-order reaction? Between a first-order and second-order reaction?

14.16 Is there any way of using the coefficients in the balanced overall equation for a reaction to predict with certainty what the exponents are in the rate law?

14.17 If the concentration of a reactant is doubled and the reaction rate is unchanged, what must be the order of the reaction with respect to that reactant?

14.18 If the concentration of a reactant is doubled and the reaction rate doubles, what must be the order of the reaction with respect to that reactant?

14.19 If the concentration of a reactant is doubled, by what factor will the rate increase if the reaction is second order with respect to that reactant?

14.20 In an experiment, the concentration of a reactant was tripled. The rate increased by a factor of 27. What is the order of the reaction with respect to that reactant?

14.21 Biological reactions usually involve the interaction of an enzyme with a *substrate*, the substance that actually undergoes the chemical change. In many cases, the rate of reaction depends on the concentration of the enzyme but is independent of the substrate concentration. What is the order of the reaction with respect to the substrate in such instances?

Concentration and Time, Half-Lives

14.22 How is the half-life of a first-order reaction affected by the initial concentration of the reactant?

14.23 How is the half-life of a second-order reaction affected by the initial reactant concentration?

14.24 How is the half-life of a zero-order reaction affected by the initial reactant concentration?

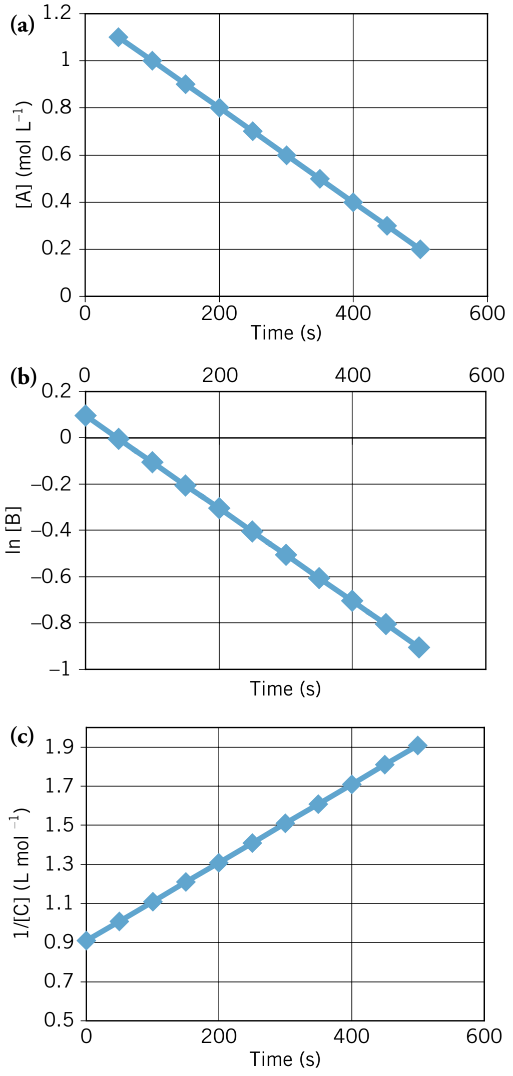
14.25 Derive the equations for $t_{1/2}$ for first-, second-, and zero-order reactions from Equations 14.5, 14.10, and 14.12, respectively.

14.26 The integrated rate law for a zero-order reaction is

$$[A]_t - [A]_0 = kt$$

Derive an equation for the half-life of a zero-order reaction.

14.27 Which of the following graphs represents the data collected for a first-order reaction? A second-order reaction? A zero-order reaction?



Effect of Temperature on Rate

14.28 What is the basic postulate of collision theory?

14.29 What two factors influence the effectiveness of molecular collisions in producing chemical change?

14.30 In terms of the kinetic theory, why does an increase in temperature increase the reaction rate?

14.31 Draw the potential energy diagram for an endothermic reaction. Indicate on the diagram the activation energy for both the forward and reverse reactions. Also indicate the heat of reaction.

14.32 Draw a potential energy diagram for an exothermic reaction and indicate on the diagram the location of the transition state.

14.33 The decomposition of carbon dioxide,

$$CO_2 \longrightarrow CO + O$$

has an activation energy of approximately 460 kJ/mol. Explain why this large value is consistent with a mechanism that involves the breaking of a C=O bond.

Reaction Mechanisms

14.34 What is the definition of an *elementary process?* How are elementary processes related to the mechanism of a reaction?

14.35 What is a *rate-determining step*?

14.36 In what way is the rate law for a reaction related to the rate-determining step?

14.37 A reaction has the following mechanism:

$$\begin{aligned} 2NO &\longrightarrow N_2O_2 \\ N_2O_2 + H_2 &\longrightarrow N_2O + H_2O \\ N_2O + H_2 &\longrightarrow N_2 + H_2O \end{aligned}$$

What is the net overall change that occurs in this reaction? Identify any intermediates in the reaction.

14.38 If the reaction, $NO_2 + CO \longrightarrow NO + CO_2$, occurs by a one-step collision process, what would be the expected rate law for the reaction? The actual rate law is rate $= k\,[NO_2]^2$. Could the reaction actually occur by a one-step collision between NO_2 and CO? Explain.

14.39 The oxidation of NO to NO_2, one of the reactions in the production of smog, appears to involve carbon monoxide. A possible mechanism is

$$\begin{aligned} CO + \cdot OH &\longrightarrow CO_2 + H\cdot \\ H\cdot + O_2 &\longrightarrow HOO\cdot \\ HOO\cdot + NO &\longrightarrow \cdot OH + NO_2 \end{aligned}$$

(The formulas with dots represent extremely reactive species with unpaired electrons and are called *free radicals.*) Write the net chemical equation for the reaction.

14.40 Show that the following two mechanisms give the same net overall reaction.

Mechanism 1

$$\begin{aligned} OCl^- + H_2O &\longrightarrow HOCl + OH^- \\ HOCl + I^- &\longrightarrow HOI + Cl^- \\ HOI + OH^- &\longrightarrow H_2O + OI^- \end{aligned}$$

Mechanism 2

$$\begin{aligned} OCl^- + H_2O &\longrightarrow HOCl + OH^- \\ I^- + HOCl &\longrightarrow ICl + OH^- \\ ICl + 2OH^- &\longrightarrow OI^- + Cl^- + H_2O \end{aligned}$$

14.41 The experimental rate law for the reaction, $NO_2 + CO \longrightarrow CO_2 + NO$, is rate $= k\,[NO_2]^2$. If the mechanism is

$$\begin{aligned} 2NO_2 &\longrightarrow NO_3 + NO \qquad \text{(slow)} \\ NO_3 + CO &\longrightarrow NO_2 + CO_2 \qquad \text{(fast)} \end{aligned}$$

show that the predicted rate law is the same as the experimental rate law.

Catalysts

14.42 How does a catalyst increase the rate of a chemical reaction?

14.43 What is a *homogeneous catalyst*? How does it function, in general terms?

14.44 What is the difference in meaning between the terms *adsorption* and *absorption*? (If necessary, use a dictionary.) Which one applies to heterogeneous catalysts?

14.45 What does the catalytic converter do in the exhaust system of an automobile? Why should leaded gasoline not be used in cars equipped with catalytic converters?

Review Problems

Measuring Rates of Reaction

14.46 The following data were collected at a certain temperature for the decomposition of sulfuryl chloride, SO_2Cl_2, a chemical used in a variety of organic syntheses.

$$SO_2Cl_2 \longrightarrow SO_2 + Cl_2$$

Time (min)	$[SO_2Cl_2]$ (mol L^{-1})
0	0.1000
1.00×10^2	0.0876
2.00×10^2	0.0768
3.00×10^2	0.0673
4.00×10^2	0.0590
5.00×10^2	0.0517
6.00×10^2	0.0453
7.00×10^2	0.0397
8.00×10^2	0.0348
9.00×10^2	0.0305
1.000×10^3	0.0267
1.100×10^3	0.0234

Make a graph of concentration versus time and determine the instantaneous rate of formation of SO_2 using the tangent to the curve at $t = 200$ minutes and $t = 600$ minutes.

14.47 The following data were collected for the decomposition of acetaldehyde, CH_3CHO (used in the manufacture of a variety of chemicals including perfumes, dyes, and plastics), into methane and carbon monoxide. The data were collected at 535 °C.

$$CH_3CHO \longrightarrow CH_4 + CO$$

$[CH_3CHO]$ (mol L^{-1})	Time (s)
0.200	0
0.153	0.20×10^2
0.124	0.40×10^2
0.104	0.60×10^2
0.090	0.80×10^2
0.079	1.00×10^2
0.070	1.20×10^2
0.063	1.40×10^2
0.058	1.60×10^2
0.053	1.80×10^2
0 049	2.00×10^2

Make a graph of concentration versus time and determine, using the tangent to the curve, the instantaneous rate of reaction of CH_3CHO after 60 seconds and after 120 seconds.

14.48 In the reaction, $3H_2 + N_2 \longrightarrow 2NH_3$, how does the rate of disappearance of hydrogen compare to the rate of disappearance of nitrogen? How does the rate of appearance of NH_3 compare to the rate of disappearance of nitrogen?

OH **14.49** For the reaction, $2A + B \longrightarrow 3C$, it was found that the rate of disappearance of B was 0.30 mol L^{-1} s^{-1}. What were the rate of disappearance of A and the rate of appearance of C?

14.50 In the combustion of hexane (a low-boiling component of gasoline),

$$2C_6H_{14}(g) + 19O_2(g) \longrightarrow 12CO_2(g) + 14H_2O(g)$$

it was found that the rate of reaction of C_6H_{14} was 1.20 mol L^{-1} s^{-1}.

(a) What was the rate of reaction of O_2?

(b) What was the rate of formation of CO_2?

(c) What was the rate of formation of H_2O?

14.51 At a certain moment in the reaction,

$$2N_2O_5 \longrightarrow 4NO_2 + O_2$$

N_2O_5 is decomposing at a rate of 2.5×10^{-6} mol L^{-1} s^{-1}. What are the rates of formation of NO_2 and O_2?

14.52 Consider the reaction,

$$CH_3Cl(g) + 3Cl_2(g) \longrightarrow CCl_4(g) + 3HCl(g).$$

(a) Express the rate of the reaction with respect to each of the reactants and products.

(b) If the instantaneous rate of the reaction with respect to HCl is 0.029 $M\,s^{-1}$, what is the instantaneous rate of the reaction?

14.53 The decomposition of phosphine, a very toxic gas, forms phosphorus and hydrogen in the following reaction:

$$4PH_3(g) \longrightarrow P_4(g) + 6H_2(g)$$

(a) Express the rate of the reaction with respect to each of the reactants and products.

(b) If the instantaneous rate of the reaction with respect to PH_3 is 0.34 $M\,s^{-1}$, what is the instantaneous rate of the reaction?

Rate Laws for Reactions

14.54 Estimate the rate of the reaction,

$$H_2SeO_3 + 6I^- + 4H^+ \longrightarrow Se + 2I_3^- + 3H_2O$$

given that the rate law for the reaction at 0 °C is

$$\text{rate} = (5.0 \times 10^5 \text{ L}^5 \text{ mol}^{-5} \text{ s}^{-1})[H_2SeO_3]\,[I^-]^3\,[H^+]^2$$

The reactant concentrations are $[H_2SeO_3] = 2.0 \times 10^{-2}$ M, $[I^-] = 2.0 \times 10^{-3}$ M, and $[H^+] = 1.0 \times 10^{-3}$ M.

14.55 Estimate the rate of the reaction,

$$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$$

given the rate law for the reaction is

$$\text{rate} = (1.3 \times 10^{11} \text{ L mol}^{-1} \text{ s}^{-1})\,[OH^-][H^+]$$

for neutral water, where $[H^+] = 1.0 \times 10^{-7}$ M and $[OH^-] = 1.0 \times 10^{-7}$ M.

OH **14.56** The oxidation of NO (released in small amounts in the exhaust of automobiles) produces the brownish-red gas NO_2, which is a component of urban air pollution.

$$2NO + O_2 \longrightarrow 2NO_2$$

The rate law for the reaction is rate = k $[NO]^2$ $[O_2]$. At 25 °C, $k = 7.1 \times 10^9$ L^2 mol^{-2} s^{-1}. What would be the rate of the reaction if [NO] = 0.0010 mol L^{-1} and $[O_2]$ = 0.034 mol L^{-1}?

14.57 The rate law for the decomposition of N_2O_5 is

$$\text{rate} = k[N_2O_5]$$

If $k = 1.0 \times 10^{-5}$ s^{-1}, what is the reaction rate when the N_2O_5 concentration is 0.0010 mol L^{-1}?

14.58 The rate law for a certain enzymatic reaction is zero order with respect to the substrate. The rate constant for the reaction is 6.4×10^2 M s^{-1}. If the initial concentration of the substrate is 0.275 mol L^{-1}, what is the initial rate of the reaction?

14.59 Radon-220 is radioactive, and decays into polonium-216. This is a first-order process, just like the radioactive decay of carbon-14, and it has a rate constant of 0.0125 s^{-1}. When the concentration of radon-220 is 1.0×10^{-9} mol L^{-1}, what is the rate of the reaction?

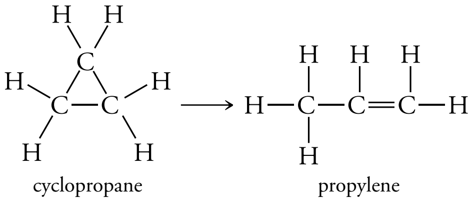
14.60 The following data were collected for the reaction

$$M + N \longrightarrow P + Q$$

Initial Concentrations (mol L^{-1})		Initial Rate of Reaction
[M]	[N]	(mol L^{-1} s^{-1})
0.010	0.010	2.5×10^{-3}
0.020	0.010	5.0×10^{-3}
0.020	0.030	4.5×10^{-2}

What is the rate law for the reaction? What is the value of the rate constant (with correct units)?

14.61 Cyclopropane, C_3H_6, is a gas used as a general anesthetic. It undergoes a slow molecular rearrangement to propylene.



At a certain temperature, the following data were obtained relating concentration and rate:

Initial Concentration of Cyclopropane (mol L^{-1})	Rate of Formation of Propylene (mol L^{-1} s^{-1})
0.050	2.95×10^{-5}
0.100	5.90×10^{-5}
0.150	8.85×10^{-5}

What is the rate law for the reaction? What is the value of the rate constant, with correct units?

14.62 The reaction of iodide ion with hypochlorite ion, OCl^- (the active ingredient in a "chlorine bleach" such as Clorox), follows the equation $OCl^- + I^- \longrightarrow OI^- + Cl^-$. It is a rapid reaction that gives the following rate data:

Initial Concentrations (mol L^{-1})		Rate of Formation of Cl^-
$[OCl^-]$	$[I^-]$	(mol L^{-1} s^{-1})
1.6×10^{-3}	1.6×10^{-3}	1.75×10^4
7.6×10^{-3}	1.6×10^{-3}	8.31×10^4
1.6×10^{-3}	9.6×10^{-3}	1.05×10^5

What is the rate law for the reaction? Determine the value of the rate constant with its correct units.

14.63 The formation of small amounts of nitric oxide, NO, in automobile engines is the first step in the formation of smog. As noted in Problem 14.56, nitric oxide is readily oxidized to nitrogen dioxide by the reaction

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$$

The following data were collected in a study of the rate of this reaction:

Initial Concentrations (mol L^{-1})		Rate of Formation of NO_2
$[O_2]$	[NO]	(mol L^{-1} s^{-1})
0.0010	0.0010	7.10
0.0037	0.0010	26.3
0.0037	0.0062	1011

What is the rate law for the reaction? What is the rate constant with its correct units?

OH **14.64** At a certain temperature, the following data were collected for the reaction, $2ICl + H_2 \rightarrow I_2 + 2HCl$:

Initial Concentrations (mol L^{-1})		Initial Rate of Formation of I_2
[ICl]	[H_2]	(mol L^{-1} s^{-1})
0.12	0.12	0.0015
0.78	0.12	0.0098
0.12	0.089	0.0011

Determine the rate law and the rate constant (with correct units) for the reaction.

14.65 The following data were obtained for the reaction of $(CH_3)_3CBr$ with hydroxide ion at 55 °C.

$$(CH_3)_3CBr + OH^- \longrightarrow (CH_3)_3COH + Br^-$$

Initial Concentrations (mol L^{-1})		Initial Rate of Formation of $(CH_3)_3COH$
[$(CH_3)_3CBr$]	[OH^-]	(mol L^{-1} s^{-1})
0.19	0.10	1.0×10^{-3}
0.46	0.10	2.4×10^{-3}
0.73	0.10	3.8×10^{-3}
0.19	0.25	1.0×10^{-3}
0.19	0.37	1.0×10^{-3}

What is the rate law for the reaction? What is the value of the rate constant (with correct units) at this temperature?

Concentration and Time

14.66 Data for the decomposition of SO_2Cl_2 according to the equation $SO_2Cl_2(g) \longrightarrow SO_2(g) + Cl_2(g)$, were given in Problem 14.46. Show graphically that these data fit a first-order rate law. Graphically determine the rate constant for the reaction.

14.67 For the data in Problem 14.47, decide graphically whether the reaction is first or second order. Graphically determine the rate constant for the reaction described in that problem.

OH ILW **14.68** The decomposition of SO_2Cl_2 described in Problem 14.46 has a first-order rate constant, $k = 2.2 \times 10^{-5}$ s^{-1} at 320 °C. If the initial SO_2Cl_2 concentration in a container is 0.0040 *M*, what will its concentration be **(a)** after 1.00 hour and **(b)** after 1.00 day?

14.69 The decomposition of acetaldehyde, CH_3CHO, was described in Problem 14.47, and the order of the reaction and the rate constant for the reaction at 530 °C were determined in Problem 14.67. If the initial concentration of acetaldehyde is 0.300 *M*, what will the concentration be **(a)** after 30 minutes, **(b)** after 180 minutes?

14.70 If it takes 75.0 min for the concentration of a reactant to drop to 25.0% of its initial value in a first-order reaction, what is the rate constant for the reaction in the units min^{-1}?

14.71 It takes 15.4 minutes for the concentration of a reactant to drop to 5.0% of its initial value in a second-order reaction. What is the rate constant for the reaction in the units L mol^{-1} min^{-1}?

14.72 The concentration of a drug in the body is often expressed in units of milligrams per kilogram of body weight. The initial dose of a drug in an animal was 25.0 mg/kg body weight. After 2.00 hours, this concentration had dropped to 15.0 mg/kg body weight. If the drug is eliminated metabolically by a first-order process, what is the rate constant for the process in units of min^{-1}?

14.73 Phosphine, PH_3, decomposes into phosphorus, P_4, and hydrogen at 680 °C, as described in Problem 14.53. If the initial concentration of phosphine is 1.1×10^{-6} g L^{-1}, and after 180 s the concentration has dropped to 0.30×10^{-6} g L^{-1}, what is the rate constant for this process in s^{-1}?

14.74 Hydrogen iodide decomposes according to the equation, $2HI(g) \longrightarrow H_2(g) + I_2(g)$. The reaction is second order and has a rate constant equal to 1.6×10^{-3} L mol^{-1} s^{-1} at 750 °C. If the initial concentration of HI in a container is 3.4×10^{-2} *M*, how many minutes will it take for the concentration to be reduced to 8.0×10^{-4} *M*?

14.75 The reaction of NOBr(g) to form NO(g) and $Br_2(g)$ is second order:

$$2NOBr(g) \longrightarrow 2NO(g) + Br_2(g)$$

The rate constant is 0.556 L mol^{-1} s^{-1} at some temperature. If the initial concentration of NOBr in the container is 0.25 *M*, how long will it take for the concentration to decrease to 0.025 *M*?

14.76 Using the information determined in Problem 14.72, calculate what the initial dose of the drug must be in order for the drug concentration 3.00 hours afterward to be 5.0 mg/kg body weight.

14.77 The second-order rate constant for the decomposition of HI at 750 °C was given in Problem 14.74. At 2.5×10^3 minutes after a particular experiment had begun, the HI concentration was equal to 4.5×10^{-4} mol L^{-1}. What was the initial molar concentration of HI in the reaction vessel?

Half-Lives

14.78 The half-life of a certain first-order reaction is 15 minutes. What fraction of the original reactant concentration will remain after 2.0 hours?

14.79 Strontium-90 has a half-life of 28 years. How long will it take for all of the strontium-90 presently on earth to be reduced to 1/32nd of its present amount?

14.80 Using the graph from Problem 14.46, determine the time required for the SO_2Cl_2 concentration to drop from 0.100 mol L^{-1} to 0.050 mol L^{-1}. How long does it take for the concentration to drop from 0.050 mol L^{-1} to 0.025 mol L^{-1}? What is the order of this reaction? (*Hint:* How is the half-life related to concentration?)

14.81 Using the graph from Problem 14.47, determine how long it takes for the CH_3CHO concentration to decrease from 0.200 mol L^{-1} to 0.100 mol L^{-1}. How long does it take the concentration to drop from 0.100 mol L^{-1} to 0.050 mol L^{-1}? What is the order of this reaction? (*Hint:* How is the half-life related to concentration?)

14.82 Hydrogen peroxide, which decomposes in a first-order reaction, has a half-life of 10 hours in air. How long will it take for hydrogen peroxide to decompose to 10% of its original concentration?

14.83 SO_2Cl_2 decomposes in a first-order process with a half life of 4.88×10^3 s. If the original concentration of SO_2Cl_2 is 0.012 *M*, how many seconds will it take for the SO_2Cl_2 to reach 0.0020 *M*?

Radiological Dating

14.84 A 500 mg sample of rock was found to have 2.45×10^{-6} mol of potassium-40 ($t_{1/2} = 1.3 \times 10^9$ yr) and 2.45×10^{-6} mol of argon-40. How old was the rock? (*Hint:* What assumption is made about the origin of the argon-40?)

ILW **14.85** A tree killed by being buried under volcanic ash was found to have a ratio of carbon-14 atoms to carbon-12 atoms of 4.8×10^{-14}. How long ago did the eruption occur?

14.86 A wooden door lintel from an excavated site in Mexico would be expected to have what ratio of carbon-14 to carbon-12 atoms if the lintel is 9.0×10^3 years old?

14.87 If a rock sample was found to contain 1.16×10^{-7} mol of argon-40, how much potassium-40 ($t_{1/2} = 1.3 \times 10^9$ yr) would also have to be present for the rock to be 1.3×10^9 years old? See assumption in Problem 14.84.

Calculations Involving the Activation Energy

14.88 The following data were collected for a reaction:

Rate Constant (L mol^{-1} s^{-1})	Temperature (°C)
2.88×10^{-4}	3.20×10^2
4.87×10^{-4}	3.40×10^2
7.96×10^{-4}	3.60×10^2
1.26×10^{-3}	3.80×10^2
1.94×10^{-3}	4.00×10^2

Determine the activation energy for the reaction in kJ/mol both graphically and by calculation using Equation 14.15. For the calculation of E_a, use the first and last sets of data in the table.

14.89 Rate constants were measured at various temperatures for the reaction, $HI(g) + CH_3I(g) \longrightarrow CH_4(g) + I_2(g)$. The following data were obtained:

Rate Constant (L mol^{-1} s^{-1})	Temperature (°C)
1.91×10^{-2}	2.05×10^2
2.74×10^{-2}	2.10×10^2
3.90×10^{-2}	2.15×10^2
5.51×10^{-2}	2.20×10^2
7.73×10^{-2}	2.25×10^2
1.08×10^{-1}	2.30×10^2

Determine the activation energy in kJ/mol both graphically and by calculation using Equation 14.15. For the calculation of E_a, use the first and last sets of data in the table.

ILW
OH **14.90** The decomposition of NOCl, $2NOCl \longrightarrow 2NO + Cl_2$, has $k = 9.3 \times 10^{-5}$ L mol^{-1} s^{-1} at 100 °C and $k = 1.0 \times 10^{-3}$ L mol^{-1} s^{-1} at 130 °C. What is E_a for this reaction in kJ mol^{-1}? Use the data at 373 K to calculate the frequency factor, *A*. What is the rate constant at 473 K?

14.91 The conversion of cyclopropane, an anesthetic, to propylene (see Problem 14.61) has a rate constant $k = 1.3 \times 10^{-6}$ s^{-1} at 673 K and $k = 1.1 \times 10^{-5}$ s^{-1} at 703 K.

(a) What is the activation energy in kJ/mol?

(b) Use the data given at 703 K to calculate the frequency factor, *A*, for this reaction?

(c) What is the rate constant for the reaction at 350 °C?

14.92 The decomposition of N_2O_5 has an activation energy of 103 kJ/mol and a frequency factor of 4.3×10^{13} s^{-1}. What is the rate constant for this decomposition at **(a)** 25 °C and **(b)** 373 K?

14.93 At 35 °C, the rate constant for the reaction

$$\underset{\text{sucrose}}{C_{12}H_{22}O_{11}} + H_2O \longrightarrow \underset{\text{glucose}}{C_6H_{12}O_6} + \underset{\text{fructose}}{C_6H_{12}O_6}$$

is $k = 6.2 \times 10^{-5}$ s^{-1}. The activation energy for the reaction is 108 kJ mol^{-1}. What is the rate constant for the reaction at 45 °C?

Mechanisms of Reactions

14.94 Consider the general reaction

$$AB + C \longrightarrow AC + B$$

If this reaction occurs in one step, what would be the expected rate law for the reaction?

14.95 Nitrogen dioxide reacts with carbon monoxide to produce nitrogen monoxide and carbon dioxide in the reaction, $NO_2(g) + CO(g) \longrightarrow NO(g) + CO_2(g)$. The first step in the reaction is proposed to be two NO_2 molecules colliding to form NO_3 and NO. The NO_3 intermediate then reacts with CO to form CO_2. What is the rate law for this proposed mechanism?

14.96 The oxidation of nitrogen monoxide with oxygen to nitrogen dioxide has a possible mechanism of

$$2NO(g) \rightleftharpoons N_2O_2(g) \qquad \text{(fast)}$$

$$N_2O_2(g) + O_2(g) \longrightarrow 2NO_2(g) \qquad \text{(slow)}$$

What are the intermediates in the proposed mechanism? What is the balanced equation for the overall reaction? What is the rate law for the reaction?

14.97 The reaction of chloroform and chlorine forms carbon tetrachloride and hydrogen chloride in the following proposed mechanism:

$Cl_2(g) \rightleftharpoons 2Cl(g)$ (fast)

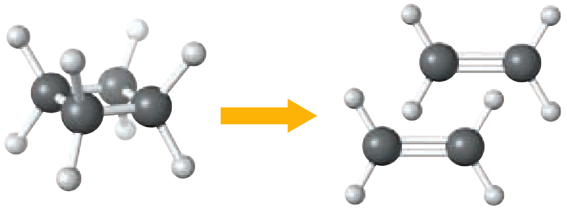
$Cl(g) + CHCl_3(g) \longrightarrow HCl(g) + CCl_3(g)$ (slow)

$CCl_3(g) + Cl(g) \longrightarrow CCl_4(g)$ (fast)

What are the intermediates in the proposed mechanism? What is the balanced equation for the overall reaction? What is the rate law for the reaction?

Additional Exercises

14.98 The following data were collected for the reaction of cyclobutane, $C_4H_8(g)$, to form ethylene, $C_2H_4(g)$.



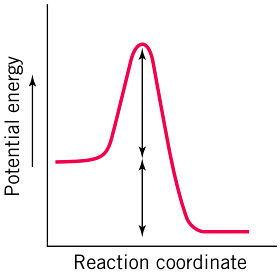
$$C_4H_8(g) \longrightarrow 2C_2H_4(g)$$

Time (min)	$[C_4H_8]$ (mol L^{-1})
0	0.00912
2.00×10^3	0.00720
4.00×10^3	0.00565
6.00×10^3	0.00447
8.00×10^3	0.00353
1.00×10^4	0.00278

Make a graph of concentration versus time for the *formation* of C_2H_4 and the decomposition of C_4H_8 on the same graph. What are the rates of formation of C_2H_4 at $t = 1.00 \times 10^3$ s and $t = 9.00 \times 10^3$ s, and the rates of decomposition of C_4H_8 at $t = 1.00 \times 10^3$ s and $t = 9.00 \times 10^3$ s? What can be said about the relationship between the values of the rates of formation and decomposition?

14.99 The age of wine can be determined by measuring the trace amount of radioactive tritium, ^3H, present in a sample. Tritium is formed from hydrogen in water vapor in the upper atmosphere by cosmic bombardment, so all naturally occurring water contains a small amount of this isotope. Once the water is in a bottle of wine, however, the formation of additional tritium from the water is negligible, so the tritium initially present gradually diminishes by a first-order radioactive decay with a half-life of 12.5 years. If a bottle of wine is found to have a tritium concentration that is 0.100 that of freshly bottled wine (i.e., $[^3H]_t = 0.100\ [^3H]_0$), what is the age of the wine?

14.100 On the following graph, label the products, reactant, $\Delta H_{reaction}$, the energy of activation (E_a) and the transition state. Is the reaction exothermic or endothermic? On the graph, draw a path for a catalyzed reaction.



OH **14.101** Carbon-14 dating can be used to estimate the age of formerly living materials because the uptake of carbon-14 from carbon dioxide in the atmosphere stops once the organism dies. If tissue samples from a mummy contain about 81.0% of the carbon-14 expected in living tissue, how old is the mummy? The half-life for decay of carbon-14 is 5730 years.

***14.102** What percentage of cesium chloride made from cesium-137 ($t_{1/2} = 30$ yr) remains after 150 years? What *chemical* product forms?

14.103 For the following reactions, predict how the rate of the reaction will change as the concentration of the reactants triple.

(a) $SO_2Cl_2 \longrightarrow SO_2 + Cl_2$ rate $= k[SO_2Cl_2]$

(b) $2HI \longrightarrow H_2 + I_2$ rate $= k[HI]^2$

(c) $ClOO \longrightarrow Cl + O_2$ rate $= k$

(d) $NH_4 + (aq) + NO_2{}^-(aq) \longrightarrow N_2(g) + 2H_2O(l)$ rate $= k[NH_4{}^+][NO_2{}^-]$

(e) $2H_2(g) + 2NO(g) \longrightarrow N_2(g) + 2H_2O(g)$ rate $= k[H_2][NO]^2$

***14.104** One of the reactions that occurs in polluted air in urban areas is $2NO_2(g) + O_3(g) \longrightarrow N_2O_5(g) + O_2(g)$. It is believed that a species with the formula NO_3 is involved in the mechanism, and the observed rate law for the overall reaction is rate $= k[NO_2][O_3]$. Propose a mechanism for this reaction that includes the species NO_3 and is consistent with the observed rate law.

OH ***14.105** Suppose a reaction occurs with the following mechanism:

(1) $2A \rightleftharpoons A_2$ (fast)

(2) $A_2 + E \longrightarrow B + C$ (slow)

in which the first step is a very rapid reversible reaction that can be considered to be essentially an equilibrium (forward and reverse reactions occurring at the same rate) and the second is a slow step.

(a) Write the rate law for the forward reaction in step (1).

(b) Write the rate law for the reverse reaction in step (1).

(c) Write the rate law for the rate-determining step.

(d) What is the chemical equation for the net reaction that occurs in this chemical change?

(e) Use the results of parts (a) and (b) to rewrite the rate law of the rate-determining step in terms of the concentrations of the reactants in the overall balanced chemical equation for the reaction.

OH **14.106** The decomposition of urea, $(NH_2)_2CO$, in 0.10 *M* HCl follows the equation

$$(NH_2)_2CO(aq) + 2H^+(aq) + H_2O \longrightarrow 2NH_4{}^+(aq) + CO_2(g)$$

At 65 °C, $k = 5.84 \times 10^{-6}$ min^{-1}, and at 75 °C, $k = 2.25 \times 10^{-5}$ min^{-1}. If this reaction is run at 85 °C starting with a urea concentration of 0.0020 *M*, how many minutes will it take for the urea concentration to drop to 0.0012 *M*?

14.107 Show that for a reaction that obeys the general rate law,

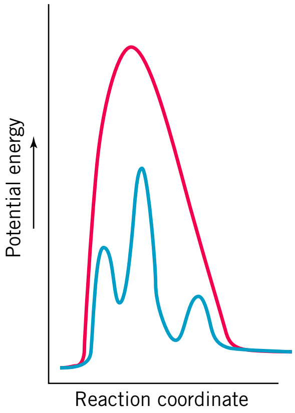
$$\text{rate} = k\,[A]^n$$

a graph of log(rate) versus log [*A*] should yield a straight line with a slope equal to the order of the reaction. For the reaction in Problem 14.46, measure the rate of the reaction at $t = 150$, 300, 450, and 600 s. Then graph log(rate) versus log$[SO_2Cl_2]$ and determine the order of the reaction with respect to SO_2Cl_2.

OH ***14.108** The rates of many reactions approximately double for each 10 °C rise in temperature. Assuming a starting temperature of 25 °C, what would the activation energy be, in kJ mol^{-1}, if the rate of a reaction were to be twice as large at 35 °C?

14.109 If the rate constant for a first-order reaction is doubled by heating the reaction what happens to the rate of the reaction if the concentration is kept the same?

***14.110** For the following potential energy diagram, which path represents a catalyzed reaction? How many steps would be proposed in the mechanism for the catalyzed reaction, and which step would be rate-determining?



***14.111** The development of a photographic image on film is a process controlled by the kinetics of the reduction of silver halide by a developer. The time required for development at a particular temperature is inversely proportional to the rate constant for the process. Below are published data on development times for Kodak's Tri-X film using Kodak D-76 developer. From these data, estimate the activation energy (in units of kJ mol^{-1}) for the development process. Also estimate the development time at 15 °C.

Temperature (°C)	Development Time (minutes)
18	10
20	9
21	8
22	7
24	6

14.112 The rate at which crickets chirp depends on the ambient temperature, because crickets are cold-blooded insects whose body temperature follows the temperature of their environment. It has been found that the Celsius temperature can be estimated by counting the number of chirps in 8 seconds and then adding 4. In other words, t_C = (number of chirps in 8 seconds) + 4.

(a) Calculate the number of chirps in 8 seconds for temperatures of 20, 25, 30, and 35 °C.

(b) The number of chirps per unit of time is directly proportional to the rate constant for a biochemical reaction involved in the cricket's chirp. On the basis of this assumption, make a graph of ln(chirps in 8 s) versus $(1/T)$. Calculate the activation energy for the biochemical reaction involved.

(c) How many chirps would a cricket make in 8 seconds at a temperature of 40 °C?

***14.113** The cooking of an egg involves the denaturation of a protein called albumen. The time required to achieve a particular degree of denaturation is inversely proportional to the rate constant for the process. This reaction has a high activation energy, $E_a = 418$ kJ mol^{-1}. Calculate how long it would take to cook a traditional three-minute egg on top of Mt. McKinley in Alaska on a day when the atmospheric pressure there is 355 torr.

***14.114** The following question is based on *Chemistry Outside the Classroom 14.1.* The reaction of hydrogen and bromine appears to follow the mechanism shown,

$$Br_2 \xrightarrow{h\nu} 2Br\cdot$$
$$Br\cdot + H_2 \longrightarrow HBr + H\cdot$$
$$H\cdot + Br_2 \longrightarrow HBr + Br\cdot$$
$$2Br\cdot \longrightarrow Br_2$$

(a) Identify the initiation step in the mechanism.

(b) Identify any propagation steps.

(c) Identify the termination step.

The mechanism also contains the reaction

$$\mathrm{H}\cdot + \mathrm{HBr} \longrightarrow \mathrm{H_2} + \mathrm{Br}\cdot$$

How does this reaction affect the rate of formation of HBr?

14.115 Radioactive samples are considered to become nonhazardous after 10 half-lives. If the half-life is less than 88 days, the radioactive sample can be stored through a decay-in-storage program in which the material is kept in a lead-lined cabinet for at least 10 half-lives. What percent of the initial material will remain after 10 half-lives?

Multi-Concept Problems

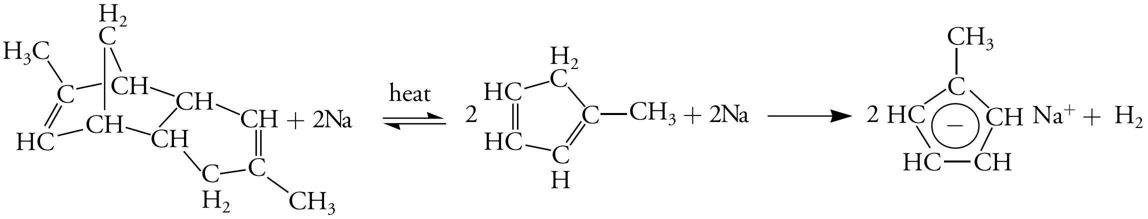
***14.116** The catalyzed decomposition of ethanol at 327 °C has a rate constant of 4.00×10^{-5} mol L^{-1} s^{-1}. The plot of concentration of ethanol versus time gives a straight line. The balanced equation for this reaction is

$$\mathrm{C_2H_5OH}(g) \longrightarrow \mathrm{C_2H_4}(g) + \mathrm{H_2}(g)$$

If the initial concentration of ethanol is 0.020 mol L^{-1}, how long will it take for the pressure to reach 1.4 atm at 327 °C?

***14.117** On December 19, 2007, the T2 Laboratories, Inc., reactor exploded in a runaway reaction. The reaction of methyl cyclopentadienyl dimer and sodium produces sodium methyl cyclopentadiene and hydrogen:

The reactor has to be cooled when its temperature reaches 182 °C. On the day of the explosion, the cooling system malfunctioned and the reactor reached 199 °C, at which point a second, more exothermic reaction began to occur. The typical energy of activation for an organic reaction is about 50 kJ/mol. The heat of this reaction is 40 kJ mol^{-1}, and the heat capacity for an industrial scale reaction (i.e., 10,000 mol) can be 7.5×10^6 J $°C^{-1}$. If the rate constant for a typical reaction is 1×10^{-5} s^{-1} at 25 °C, what will be the rate constant, if all the heat is supplied to the reaction all at once, without any external cooling? If the reaction were started at 182 °C, would the reaction reach 199 °C if all the heat were released at once?



Exercises in Critical Thinking

14.118 Provide three examples of ordinary occurrences that mimic a reaction mechanism and have a rate-limiting step.

14.119 Can a reaction have a negative activation energy? Explain your response.

14.120 Assume you have a three-step mechanism. Would the potential energy diagram have three peaks? If so, how would you distinguish the rate-limiting step?

14.121 What range of ages can ^{14}C dating reliably determine?

14.122 Why are initial reaction rates used to determine rate laws?

14.123 If a reaction is reversible (i.e., the products can react to re-form the reactants), what would the rate law look like?

14.124 The ozone layer protects us from high-energy radiation. The description of how the ozone layer works is a kinetics problem concerning the formation and destruction of ozone to produce a steady state. How can we write this mathematically, assuming that the processes are elementary reactions?

14.125 How would you measure the rate of an extremely fast reaction?

14.126 For a reaction done on the ton scale, would a heterogeneous catalyst or a homogeneous catalyst be more effective to use?

14.127 Can we use molality instead of molarity in constructing rate laws? Can mole fractions be used?

15 Chemical Equilibrium

Chapter Outline

15.1 | Dynamic Equilibrium in Chemical Systems

15.2 | Equilibrium Laws

15.3 | Equilibrium Laws Based on Pressures or Concentrations

15.4 | Equilibrium Laws for Heterogeneous Reactions

15.5 | Position of Equilibrium and the Equilibrium Constant

15.6 | Equilibrium and Le Châtelier's Principle

15.7 | Calculating Equilibrium Constants

15.8 | Using Equilibrium Constants to Calculate Concentrations

It is an amazing fact that feeding the earth's enormous (and growing) population relies on a simple chemical equilibrium involving the reaction of nitrogen with hydrogen to form ammonia. This equilibrium, which is one of those discussed in this chapter, is used to manufacture more than 100 million tons of ammonia annually, with most of it going to agricultural uses as a fertilizer. In the pages ahead we will take a close look at chemical equilibria and examine the factors that affect the relative amounts of reactants and products present when a dynamic chemical equilibrium is achieved. Inga Spence/Alamy

This Chapter in Context

In Chapter 14 you learned that most chemical reactions slow down as the reactants are consumed and the products form. The focus there was learning about the factors that affect how *fast* the reactant and product concentrations change. In this and the following four chapters we will turn our attention to the ultimate fate of chemical systems, *dynamic chemical equilibrium*—the situation that exists when the concentrations cease to change.

You have already encountered the concept of a dynamic equilibrium several times in this book. Recall that such an equilibrium is established when two opposing processes occur at equal rates. In a liquid–vapor equilibrium, for example, the processes are evaporation and condensation. In a chemical equilibrium, such as the ionization of a weak acid, they are the forward and reverse reactions represented by the chemical equation. Understanding the factors that affect equilibrium systems is important not only in chemistry but in other sciences as well. They apply to biology because living cells must control the concentrations of substances within them in order to survive. And they are fundamental in understanding chemical reactions that affect many current environmental problems, including global warming, acid rain, and stratospheric ozone depletion.

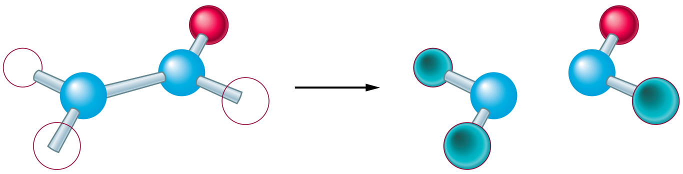
15.1 | Dynamic Equilibrium in Chemical Systems

We begin our discussion of equilibrium by examining principles that apply to chemical systems in general. In Chapters 16 through 18 we will focus on equilibria in aqueous solutions. Then in Chapter 19 we will tie together the concept of chemical equilibrium with the energetics of chemical change.

A Molecular Interpretation of Equilibrium

Let's review the process by which a system reaches equilibrium. For this purpose, we'll examine the reaction for the decomposition of gaseous N_2O_4 into NO_2.

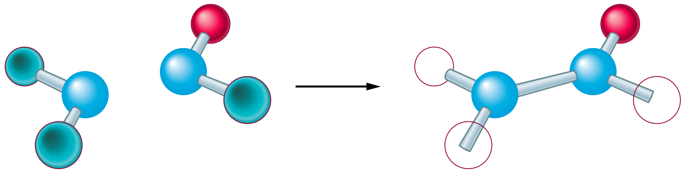
$$N_2O_4(g) \longrightarrow 2NO_2(g) \tag{15.1}$$



If this reaction were irreversible, over time the concentration of N_2O_4 would continue to drop until it reached zero and all of the N_2O_4 had reacted. However, if we look at what actually happens in the reaction (Figure 15.1), we see that the N_2O_4 concentration decreases until it reaches some final, steady nonzero value. Meanwhile, the NO_2 concentration rises until it also reaches a final steady value.

The explanation for these observations is that the reaction above is actually able to proceed in both directions. As NO_2 is formed and starts to accumulate in the reaction mixture, collisions between NO_2 molecules are able to produce N_2O_4 molecules, so the following reaction begins to occur.

$$2NO_2(g) \longrightarrow N_2O_4(g) \tag{15.2}$$



As the NO_2 concentration rises because of Equation 15.1, the rate of the reaction in Equation 15.2 increases. Because N_2O_4 is being remade by Equation 15.2, the drop in N_2O_4 concentration starts to slow down. As you see in Figure 15.1, eventually a state is reached in which the concentrations cease to change. At this point the rate of the forward reaction (Equation 15.1) is equal to the rate of the reverse reaction (Equation 15.2); N_2O_4 is being formed as fast as it's decomposing, and we've reached *dynamic equilibrium*. As you learned in Section 5.3, when we write the equation to describe the equilibrium, we use double arrows ($\rightleftharpoons$).

$$N_2O_4(g) \rightleftharpoons 2NO_2(g) \tag{15.3}$$

Most chemical systems eventually reach a state of dynamic equilibrium, given enough time. Sometimes, though, this equilibrium is extremely difficult (or even impossible) to detect, because in some reactions the amounts of either the reactants or products present at equilibrium are virtually zero. For instance, in water vapor at room temperature there are no detectable amounts of either H_2 or O_2 from the equilibrium

$$2H_2O(g) \rightleftharpoons 2H_2(g) + O_2(g)$$

Water molecules are so stable that we can't detect whether any of them decompose. Even in cases such as this, however, it is often *convenient* to assume that an equilibrium does exist.

■ For the equilibrium $A \rightleftharpoons B$, the reaction read from left to right is the ***forward reaction***; the reaction read from right to left is the ***reverse reaction***.

$A \longrightarrow B$ (forward reaction)
$A \longleftarrow B$ (reverse reaction)

Remember that even after equilibrium has been reached, both the forward and reverse reactions continue to occur.

The Meaning of *Reactants* and *Products* in a Chemical Equilibrium

For the forward reaction in the equilibrium described by Equation 15.3, N_2O_4 is the reactant and NO_2 is the product. But the reverse reaction is also occurring, where NO_2 is the reactant and N_2O_4 is the product. When the system is at equilibrium, the usual definitions of reactant and product don't make a lot of sense. *In these situations, when we use the term* **reactants**, *we simply mean those substances written to the left of the double arrows. Similarly, we use the term* **products** *to mean the substances to the right of the double arrows.*

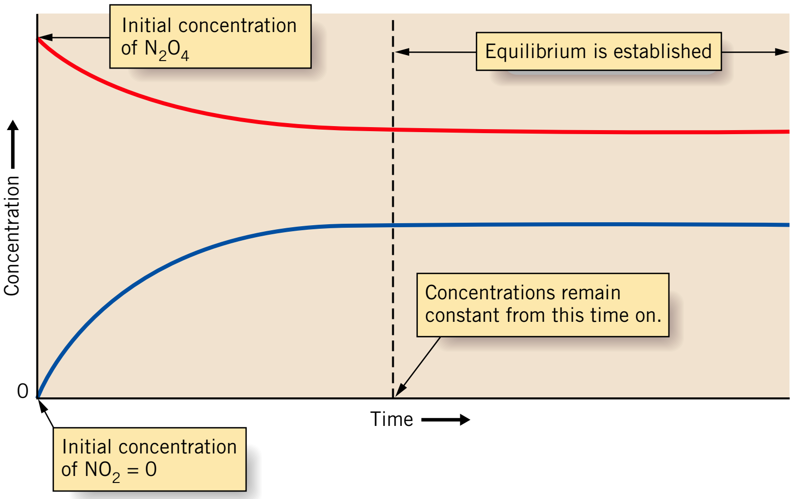


Figure 15.1 | **The approach to equilibrium.** In the decomposition of $N_2O_4(g)$ into $NO_2(g)$, given by the equation $N_2O_4(g) \longrightarrow 2NO_2(g)$, the concentrations of the N_2O_4 and NO_2 change relatively fast at first. As time passes, the concentrations change more and more slowly. When equilibrium is reached, the concentrations of N_2O_4 and NO_2 no longer change with time; they remain constant.

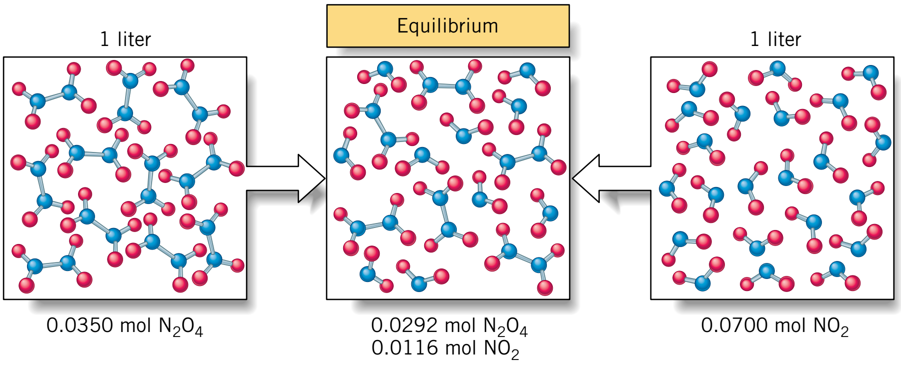

Figure 15.2 | **Reaction reversibility for the equilibrium**

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

The same equilibrium composition is reached from either the forward or reverse direction, provided the *overall* system composition is the same.

Approaching Equilibrium from Reactants or Products

One of the interesting (and useful) things about a chemical equilibrium is that the composition of an equilibrium mixture is independent of whether we begin the reaction from the "reactant side" or the "product side." For example, suppose we set up the two experiments shown in Figure 15.2. In the first 1.00 L flask we place 0.0350 mol N_2O_4. Because no NO_2 is present, some N_2O_4 must decompose for the mixture to reach equilibrium, so the reaction in Equation 15.3 will proceed in the forward direction (i.e., from left to right). When equilibrium is reached, we find the concentration of N_2O_4 has dropped to 0.0292 mol L^{-1} and the concentration of NO_2 has increased from zero to 0.0116 mol L^{-1}.

■ Recall that the unit mol L^{-1} (or mol/L) is molarity, *M*.

In the second 1.00 L flask we place 0.0700 mol of NO_2 (*precisely* the amount of NO_2 that would form if 0.0350 mol of N_2O_4—the amount placed in the first flask—decomposed completely). In this second flask there is no N_2O_4 present initially, so NO_2 molecules must combine, following the reverse reaction (right to left) in Equation 15.3, to give enough N_2O_4 to achieve equilibrium. When we measure the concentrations at equilibrium in the second flask, we find, once again, 0.0292 mol L^{-1} of N_2O_4 and 0.0116 mol L^{-1} of NO_2.

■ Stoichiometrically, 0.0700 mol of NO_2 could be formed from 0.0350 mol of N_2O_4, since the ratio of NO_2 to N_2O_4 is 2:1.

We see here that the same equilibrium composition is reached whether we begin with pure NO_2 or pure N_2O_4, as long as the *total* amount of nitrogen and oxygen to be divided between these two substances is the same. Similar observations apply to other chemical systems as well, which leads to the following generalization.

TOOLS

Approach to equilibrium

> For a given *overall* system composition, we always reach the same equilibrium concentrations whether equilibrium is approached from the forward or reverse direction.

There are times when it is very convenient to be able to imagine the approach to equilibrium starting from the product side of the equation.

15.2 | Equilibrium Laws

For any chemical system at equilibrium, there exists a simple, predictable relationship among the molar concentrations of the reactants and products. To study this, let's consider the gaseous reaction of hydrogen with iodine to form hydrogen iodide.

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

Figure 15.3 shows the results of several experiments measuring equilibrium amounts of each gas, starting with different amounts of the reactants and product in a 10.0 L reaction vessel. When equilibrium is reached, the amounts of H_2, I_2, and HI are different for each experiment, as are their molar concentrations. This isn't particularly surprising, but what is amazing is that the relationship among the concentrations is very simple.

■ The molar concentrations are obtained by dividing the number of moles of each substance by the volume, 10.0 L.

For each experiment in Figure 15.3, if we square the molar concentration of HI at equilibrium and then divide this by the product of the equilibrium molar concentrations

Figure 15.3 | **Four experiments to study the equilibrium among H_2, I_2, and HI gases.** Different amounts of the reactants and product are placed in a 10.0 L reaction vessel at 440 °C where the gases establish the equilibrium

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g).$$

When equilibrium is reached, different amounts of reactants and products remain in each experiment, which give different equilibrium concentrations.

of H_2 and I_2, we obtain the same numerical value. This is shown in Table 15.1, where we have once again used square brackets around formulas as symbols for molar concentrations.

The fraction used to calculate the values in the last column of Table 15.1,

$$\frac{[HI]^2}{[H_2][I_2]}$$

is called the **mass action expression.**[1] The origin of this term isn't important; just consider it a name we use to refer to this fraction. The numerical value of the mass action expression is called the **reaction quotient**, and is often symbolized by the letter ***Q***. For this reaction, we can write

$$Q = \frac{[HI]^2}{[H_2][I_2]}$$

This equation applies for any set of H_2, I_2, and HI concentrations, whether we are at equilibrium or not.

In Table 15.1, notice that when H_2, I_2, and HI are in dynamic equilibrium at 440 °C, Q is equal to essentially the same constant value of 49.5. In fact, if we repeated the experiments in Figure 15.3 over and over again starting with different amounts of H_2, I_2, and HI, we would still obtain the same reaction quotient, provided the systems had reached equilibrium and the temperature was 440 °C. Therefore, for this reaction at equilibrium we can write

$$\frac{[HI]^2}{[H_2][I_2]} = 49.5 \qquad \text{(at equilibrium at 440 °C)} \tag{15.4}$$

---

[1] The mass action expression is derived using thermodynamics, which we'll discuss in Chapter 19. Technically, each concentration in the mass action expression should be divided by its value at standard state before inserting it into the expression. This makes the value of any mass action expression unitless. *For substances in solution*, the standard state is an effective molar concentration of 1 *M*, so we would have to divide each concentration by 1 *M* (1 mol L^{-1}), which makes no difference in the numerical value of the mass action expression as long as all concentrations are molarities. *For gases*, the standard state is 1 bar, so we would have to divide each gas concentration by its concentration at that pressure, or each gas partial pressure by 1 bar. For simplicity, we'll leave the standard state values out of our mass action expressions. Later we'll see that these values are lumped into the numerical value of the expression.

Table 15.1 Equilibrium Concentrations and the Value of the Mass Action Expression

	Equilibrium Concentrations (mol L^{-1})			
Experiment	**[H_2]**	**[I_2]**	**[HI]**	$\frac{[HI]^2}{[H_2][I_2]}$
I	0.0222	0.0222	0.156	$(0.156)^2/(0.0222)(0.0222) = 49.4$
II	0.0350	0.0450	0.280	$(0.280)^2/(0.0350)(0.0450) = 49.8$
III	0.0150	0.0135	0.100	$(0.100)^2/(0.0150)(0.0135) = 49.4$
IV	0.0442	0.0442	0.311	$(0.311)^2/(0.0442)(0.0442) = 49.5$
				Average = 49.5

This relationship is called the **equilibrium law** for the system. Significantly, it tells us that for a mixture of these three gases to be at equilibrium at 440 °C, the value of the mass action expression (the reaction quotient) must equal 49.5. If the reaction quotient has any other value, then the gases are not in equilibrium at this temperature. The constant 49.5, which characterizes this equilibrium system, is called the **equilibrium constant**. The equilibrium constant is usually symbolized by $\boldsymbol{K_c}$ (we use the subscript **c** because we write the mass action expression using molar concentrations). Thus, we can state the equilibrium law as follows:

$$\frac{[HI]^2}{[H_2][I_2]} = K_c = 49.5 \qquad \text{(at 440 °C)} \tag{15.5}$$

■ Equation 15.5 can be called the equilibrium condition for the reaction of H_2, I_2, and HI at 440 °C.

It is often useful to think of an equilibrium law such as Equation 15.5 as a *condition* that must be met for equilibrium to exist.

Requirement for equilibrium

> For chemical equilibrium to exist in a reaction mixture, the value of the reaction quotient Q must be equal to the equilibrium constant, K_c.

As you may have noticed, we have repeatedly mentioned the temperature when referring to the value of K_c. This is because the value of the equilibrium constant changes when the temperature changes. Thus, if we had performed the experiments in Figure 15.3 at a temperature other than 440 °C, we would have obtained a different value for K_c.

■ In general, it is necessary to specify the temperature when giving a value of K_c, because K_c changes when the temperature changes. For example, for the reaction

$$CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g)$$

$K_c = 1.78 \times 10^{-3}$ at 800 °C
$K_c = 4.68 \times 10^{-2}$ at 1000 °C
$K_c = 5.67$ at 1500 °C

Homogeneous Equilibria

A **homogeneous reaction** (or **homogeneous equilibrium**) is one in which all of the reactants and products are in the same gas or liquid phase. Equilibria among gases, such as the one described above, are homogeneous because all gases mix freely with each other, so a single phase exists. There are also many equilibria in which reactants and products are dissolved in the same liquid phase, such as an aqueous solution. You will study equilibria in aqueous solutions in Chapters 17 and 18.

An important fact about homogeneous reactions is that the mass action expression and the equilibrium law can *always* be predicted from the coefficients of the balanced chemical equation for the reaction. For example, for the general chemical equation

$$dD + eE \rightleftharpoons fF + gG \tag{15.6}$$

where D, E, F, and G represent chemical formulas and d, e, f, and g are their coefficients, the mass action expression is

$$\frac{[F]^f[G]^g}{[D]^d[E]^e}$$

> *The exponents in the mass action expression are the same as the stoichiometric coefficients in the balanced equation.*

The condition for equilibrium in this reaction is given by the equation

$$\frac{[F]^f[G]^g}{[D]^d[E]^e} = K_c \tag{15.7}$$

where the only concentrations that satisfy the equation are *equilibrium concentrations.*

Notice that in writing the mass action expression the molar concentrations of the products are always placed in the numerator and those of the reactants are always placed in the denominator. Also note that after being raised to appropriate powers the concentration terms are *multiplied*, not added.

■ Notice that even though we cannot predict the *rate law* from the balanced overall equation, we can predict the *equilibrium law*.

TOOLS

The equilibrium law

Example 15.1
Writing the Equilibrium Law

Most of the hydrogen produced in the United States is derived from methane in natural gas, using the forward reaction of the equilibrium

$$CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g)$$

What is the equilibrium law for this reaction?

■ **Analysis:** This is a straightforward question, and finding the answer is a task you will repeat many times as you work problems dealing with chemical equilibria.

■ **Assembling the Tools:** The pattern we follow is represented by Equations 15.6 and 15.7, simply substituting formulas and coefficients.

■ **Solution:** The equilibrium law sets the mass action expression equal to the equilibrium constant. To form the mass action expression, we place the concentrations of the products in the numerator and the concentrations of the reactants in the denominator. The coefficients in the balanced chemical equation become exponents on the concentrations. The equilibrium law is

$$\frac{[CO][H_2]^3}{[CH_4][H_2O]} = K_c$$

■ **Is the Answer Reasonable?** Check to see that the products are on top of the fraction and that the reactants are on the bottom. Also check the exponents and be sure they are the same as the coefficients in the balanced chemical equation. Notice that we omit writing the exponent when it is equal to 1.

Practice Exercises

15.1 | The equilibrium law for a reaction is

$$\frac{[NO_2]^4}{[N_2O_3]^2[O_2]} = K_c$$

Write the chemical equation for the equilibrium. (*Hint:* In the equilibrium law, remember where the reactant and product concentrations go and what the exponents mean.)

15.2 | Write the equilibrium law for each of the following:

(a) $2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(g)$

(b) $CH_4(g) + 2O_2(g) \rightleftharpoons CO_2(g) + 2H_2O(g)$

The rule that we always write the concentrations of the products in the numerator of the mass action expression and the concentrations of the reactants in the denominator is not required by nature. Rather, it is a convention chemists have agreed to follow. Certainly, if the mass action expression is equal to a constant, its reciprocal is also equal to a constant (let's call it K'_c)

$$\frac{[\mathrm{HI}]^2}{[\mathrm{H_2}][\mathrm{I_2}]} = K_c \qquad \frac{[\mathrm{H_2}][\mathrm{I_2}]}{[\mathrm{HI}]^2} = \frac{1}{K_c} = K'_c$$

Having a set rule for constructing the mass action expression is very useful; it means we don't have to specify the mass action expression when we give the equilibrium constant for a reaction. For example, suppose we're told that at a particular temperature $K_c = 10.0$ for the reaction

$$2\mathrm{NO_2}(g) \rightleftharpoons \mathrm{N_2O_4}(g)$$

From the chemical equation, we can write the correct mass action expression and the correct equilibrium law.

$$K_c = \frac{[\mathrm{N_2O_4}]}{[\mathrm{NO_2}]^2} = 10.0$$

The balanced chemical equation contains all the information we need to write the equilibrium law.

Manipulating Equilibrium Laws

TOOLS

Manipulating equilibrium equations

Sometimes it is useful to be able to combine chemical equilibria to obtain the equation for some other reaction of interest. In doing this, we perform various operations such as reversing an equation, multiplying the coefficients by some factor, and adding the equations to give the desired equation. In our discussion of thermochemistry, you learned how such manipulations affect ΔH values. Some different rules apply to changes in the mass action expressions and equilibrium constants.

Changing the Direction of an Equilibrium

When the direction of an equation is reversed, the new equilibrium constant is the reciprocal of the original. You have just seen this in the preceding discussion. As another example, when we reverse the equilibrium

$$\mathrm{PCl_3} + \mathrm{Cl_2} \rightleftharpoons \mathrm{PCl_5} \qquad K_c = \frac{[\mathrm{PCl_5}]}{[\mathrm{PCl_3}][\mathrm{Cl_2}]}$$

we obtain

$$\mathrm{PCl_5} \rightleftharpoons \mathrm{PCl_3} + \mathrm{Cl_2} \qquad K'_c = \frac{[\mathrm{PCl_3}][\mathrm{Cl_2}]}{[\mathrm{PCl_5}]}$$

The mass action expression for the second reaction is the reciprocal of that for the first, so K'_c equals $1/K_c$.

Multiplying the Coefficients by a Factor

When the coefficients in an equation are multiplied by a factor, the equilibrium constant is raised to a power equal to that factor. For example, suppose we multiply the coefficients of the equation

$$\mathrm{PCl_3} + \mathrm{Cl_2} \rightleftharpoons \mathrm{PCl_5} \qquad K_c = \frac{[\mathrm{PCl_5}]}{[\mathrm{PCl_3}][\mathrm{Cl_2}]}$$

by 2. This gives

$$2\mathrm{PCl_3} + 2\mathrm{Cl_2} \rightleftharpoons 2\mathrm{PCl_5} \qquad K''_c = \frac{[\mathrm{PCl_5}]^2}{[\mathrm{PCl_3}]^2[\mathrm{Cl_2}]^2}$$

Comparing mass action expressions, we see that $K''_c = K_c^2$.

Adding Chemical Equilibria

When chemical equilibria are added, their equilibrium constants are multiplied. For example, suppose we add the following two equations.

$$2N_2 + O_2 \rightleftharpoons 2N_2O \qquad K_{c1} = \frac{[N_2O]^2}{[N_2]^2[O_2]}$$

$$2N_2O + 3O_2 \rightleftharpoons 4NO_2 \qquad K_{c2} = \frac{[NO_2]^4}{[N_2O]^2[O_2]^3}$$

$$2N_2 + 4O_2 \rightleftharpoons 4NO_2 \qquad K_{c3} = \frac{[NO_2]^4}{[N_2]^2[O_2]^4}$$

■ We have numbered the equilibrium constants just to distinguish one from the other.

If we multiply the mass action expression for K_{c1} by that for K_{c2}, we obtain the mass action expression for K_{c3}.

$$\frac{\cancel{[N_2O]^2}}{[N_2]^2[O_2]} \times \frac{[NO_2]^4}{\cancel{[N_2O]^2}\,[O_2]^3} = \frac{[NO_2]^4}{[N_2]^2[O_2]^4}$$

Therefore, $K_{c1} \times K_{c2} = K_{c3}$.

Practice Exercises

15.3 | At 25 °C, $K_c = 7.0 \times 10^{25}$ for the reaction

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

What is the value of K_c for the reaction: $SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2}O_2(g)$? (*Hint:* What do you have to do with the original equation to obtain the new equation?)

15.4 | At 25 °C, the following reactions have the equilibrium constants noted to the right of their equations.

$$2CO(g) + O_2(g) \rightleftharpoons 2CO_2(g) \qquad K_c = 3.3 \times 10^{91}$$

$$2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(g) \qquad K_c = 9.1 \times 10^{80}$$

Use these data to calculate K_c for the reaction

$$H_2O(g) + CO(g) \rightleftharpoons CO_2(g) + H_2(g)$$

15.3 | Equilibrium Laws Based on Pressures or Concentrations

When all of the reactants and products are gases, we can formulate mass action expressions in terms of partial pressures as well as molar concentrations. This is possible because the molar concentration of a gas is proportional to its partial pressure (Figure 15.4). If we start with the ideal gas law,

$$PV = nRT$$

and solve for P, we can write the result as

$$P = \left(\frac{n}{V}\right)RT$$

The quantity n/V has units of mol/L and is simply the molar concentration. Therefore, we can write

$$P = (\text{molar concentration}) \times RT \qquad \textbf{(15.8)}$$

■ If you double the number of molecules of a gas per liter without changing the temperature, you double the pressure.

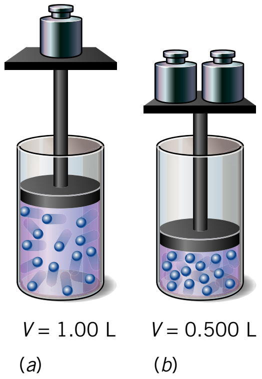

Figure 15.4 | **Molar concentration in a gas is proportional to the pressure.** Going from (*a*) to (*b*), we double the pressure, which halves the volume. This packs twice as many molecules into a unit volume, thereby doubling the molar concentration.

This equation applies whether the gas is by itself in a container or part of a mixture. In the case of a gas mixture, P is the partial pressure of the gas.

The relationship expressed in Equation 15.8 lets us write the mass action expression for reactions between gases either in terms of molarities or partial pressures. However, when we make a switch we can't expect the numerical values of the equilibrium constants to be the same, so we use two different symbols for K. When molar concentrations are used, we use the symbol K_c. When partial pressures are used, then $\boldsymbol{K_P}$ is the symbol. For example, the equilibrium law for the reaction of nitrogen with hydrogen to form ammonia

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

can be written in either of the following two ways:

$$\frac{[NH_3]^2}{[N_2][H_2]^3} = K_c \qquad \left(\begin{array}{l}\text{because molar concentrations are}\\ \text{used in the mass action expression}\end{array}\right)$$

$$\frac{P_{NH_3}^2}{P_{N_2}P_{H_2}^3} = K_P \qquad \left(\begin{array}{l}\text{because partial pressures are used}\\ \text{in the mass action expression}\end{array}\right)$$

The equilibrium molar concentrations can be used to calculate K_c, whereas the equilibrium partial pressures can be used to calculate K_P.

Example 15.2
Writing Expressions for K_P

Most of the world's supply of methanol, CH_3OH, is produced by the following reaction:

$$CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$$

What is the expression for K_P for this equilibrium?

Analysis: This is very similar to Example 15.1, except we're writing the equilibrium law for K_P instead of K_c.

Assembling the Tools: Our tools are the templates given by Equations 15.6 and 15.7, but with partial pressures instead of molar concentrations in the mass action expression.

Solution: In the mass action expression, it's always products over reactants. In this case we use partial pressures raised to powers equal to the coefficients in the balanced equation. The expression for K_P for the reaction is

$$K_P = \frac{P_{CH_3OH}}{(P_{CO})(P_{H_2})^2}$$

Is the Answer Reasonable? Check to see that the mass action expression gives products over reactants, and not the other way around. Check each exponent against the coefficients in the balanced chemical equation.

Practice Exercises

15.5 | Write the equilibrium law in terms of partial pressures for the following reaction. (*Hint:* Keep in mind how the mass action expression is written.)

$$2N_2(g) + O_2(g) \rightleftharpoons 2N_2O(g)$$

15.6 | Using partial pressures, write the equilibrium law for the reaction

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

Relating K_P to K_c

For some reactions K_P is equal to K_c, but for many others the two constants have different values. It is therefore desirable to have a way to calculate one from the other. Converting between K_P and K_c uses the relationship between partial pressure and molarity. Equation 15.8 can be used to change K_P to K_c by substituting

$$(\text{molar concentration}) \times RT$$

for the partial pressure of each gas in the mass action expression for K_P. Similarly, K_c can be changed to K_P by solving Equation 15.8 for the molar concentrations, and then substituting the result, P/RT, into the appropriate expression for K_c. This sounds like a lot of work, and it is. Fortunately, there is a general equation (Equation 15.9), which can be derived from these relationships, that we can use to make the conversions simple.

$$K_P = K_c(RT)^{\Delta n_g} \tag{15.9}$$

TOOLS

Converting between K_P and K_c

In this equation, the value of Δn_g is equal to the change in the *number of moles of gas* in going from the reactants to the products.

$$\Delta n_g = \left(\begin{matrix}\text{moles of}\\ \textit{gaseous}\text{ products}\end{matrix}\right) - \left(\begin{matrix}\text{moles of}\\ \textit{gaseous}\text{ reactants}\end{matrix}\right) \tag{15.10}$$

We use the coefficients of the balanced equation for the reaction to calculate the numerical value of Δn_g. For example, the equation

$$2N_2(g) + O_2(g) \rightleftharpoons 2N_2O(g)$$

tells us that two moles of N_2O are formed when two moles of N_2 and one mole of O_2 react. In other words, two moles of gaseous product are formed from a total of three moles of gaseous reactants. That's a decrease of one mole of gas, so Δn_g for this reaction equals -1.

For some reactions, the value of Δn_g is equal to zero. An example is the decomposition of HI.

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$$

If we take the coefficients to mean moles, there are two moles of gas on each side of the equation, so $\Delta n_g = 0$. Because (RT) raised to the zero power is equal to 1, $K_P = K_c$.

Example 15.3
Converting between K_P and K_c

At 500 °C, the reaction between N_2 and H_2 to form ammonia

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

has $K_c = 6.0 \times 10^{-2}$. What is the numerical value of K_P for this reaction?

■ **Analysis:** Quite clearly, this conversion will require Equation 15.9. However, before we can begin we have to be sure about the units of R and T. When used to stand for temperature, a capital letter T in an equation always means the absolute temperature. Therefore we will have to convert the Celsius temperature to kelvins. Next we must choose an appropriate value for R. Referring back to Equation 15.8, if the partial pressures are expressed in atm and the concentration in mol L^{-1}, the only value of R that includes all of these units (L, mol, atm, and K) is $R = 0.0821$ L atm mol^{-1} K^{-1}, and this is the *only* value of R that can be used in Equation 15.9.

Assembling the Tools: As we've noted, we are going to have to substitute into Equation 15.9.

$$K_P = K_c\,(RT)^{\Delta n_g}$$

To three significant figures, the temperature in kelvins is calculated by the equation: $T_K = T_{°C} + 273$. We also have to calculate Δn_g using Equation 15.10.

$$\Delta n_g = \begin{pmatrix}\text{moles of} \\ \textit{gaseous}\text{ products}\end{pmatrix} - \begin{pmatrix}\text{moles of} \\ \textit{gaseous}\text{ reactants}\end{pmatrix}$$

Solution: Let's start by calculating Δn_g. Interpreting the coefficients in the equation to stand for moles, we have two moles of gaseous products and four moles of gaseous reactants [1 mol $N_2(g)$ and 3 mol $H_2(g)$]. Therefore, $\Delta n_g = (2) - (1 + 3) = -2$.

Assembling the data, then, we have

$$K_c = 6.0 \times 10^{-2} \qquad \Delta n_g = -2$$
$$T = (500 + 273)\text{ K} = 773\text{ K} \qquad R = 0.0821\text{ L atm mol}^{-1}\text{ K}^{-1}$$

Substituting these into the equation for K_P gives

$$\begin{aligned} K_P &= (6.0 \times 10^{-2}) \times [(0.0821) \times (773)]^{-2} \\ &= (6.0 \times 10^{-2}) \times (63.5)^{-2} \\ &= 1.5 \times 10^{-5} \end{aligned}$$

In this case, K_P has a numerical value quite different from that of K_c.

Is the Answer Reasonable? In working these problems, check to be sure you have used the correct value of R and that the temperature is expressed in kelvins. Notice that if Δn_g is negative, as it is in this reaction, the expression $(RT)^{\Delta n_g}$ will be less than one. That should make K_P smaller than K_c, which is consistent with our results.

Practice Exercises

15.7 | Nitrous oxide, N_2O, is a gas used as an anesthetic; it is sometimes called "laughing gas." This compound has a strong tendency to decompose into nitrogen and oxygen following the equation

$$2N_2O(g) \rightleftharpoons 2N_2(g) + O_2(g)$$

but the reaction is so slow that the gas appears to be stable at room temperature (25 °C). The decomposition reaction has $K_c = 7.3 \times 10^{34}$. What is the value of K_P for this reaction at 25 °C? (*Hint:* Be careful in calculating Δn_g.)

15.8 | Methanol, CH_3OH, is a promising fuel that can be synthesized from carbon monoxide and hydrogen according to the equation

$$CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$$

For this reaction at 200 °C, $K_P = 3.8 \times 10^{-2}$. Do you expect K_P to be larger or smaller than K_c? Calculate the value of K_c at this temperature.

15.4 | Equilibrium Laws for Heterogeneous Reactions

When more than one phase exists in a reaction mixture, we call it a **heterogeneous reaction.** A common example is the combustion of charcoal, in which a solid fuel reacts with gaseous oxygen. Another is the thermal decomposition of sodium bicarbonate (baking soda), which occurs when the compound is sprinkled on a fire.

$$2NaHCO_3(s) \longrightarrow Na_2CO_3(s) + H_2O(g) + CO_2(g)$$

Safety-minded cooks keep a box of baking soda nearby because this reaction makes it an excellent fire extinguisher for burning fats or oil. The fire is smothered by the products of the reaction.

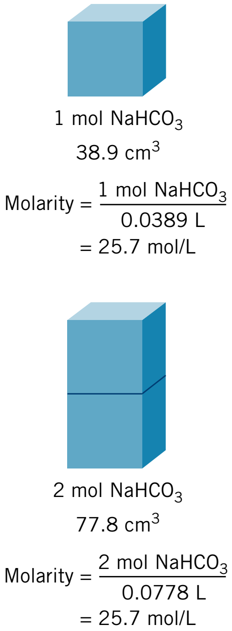
If $NaHCO_3$ is placed in a sealed container so that no CO_2 or H_2O can escape, the gases and solids come to a heterogeneous equilibrium.

$$2NaHCO_3(s) \rightleftharpoons Na_2CO_3(s) + H_2O(g) + CO_2(g)$$

Following the procedure we developed earlier, we would write the equilibrium law for this reaction as

$$\frac{[Na_2CO_3(s)][H_2O(g)][CO_2(g)]}{[NaHCO_3(s)]^2} = K$$

However, the equilibrium law for reactions involving pure liquids and solids can be written in an even simpler form. This is because the concentration of a pure liquid or solid is unchangeable at a given temperature. *For any pure liquid or solid, the ratio of amount of substance to volume of substance is a constant.* For example, if we had a 1 mole crystal of $NaHCO_3$, it would occupy a volume of 38.9 cm^3. Two moles of $NaHCO_3$ would occupy twice this volume, 77.8 cm^3 (Figure 15.5), but the *ratio* of moles to liters (i.e., the molar concentration) remains the same.



1 mol $NaHCO_3$
38.9 cm^3
Molarity = $\frac{1 \text{ mol } NaHCO_3}{0.0389 \text{ L}}$
= 25.7 mol/L
2 mol $NaHCO_3$
77.8 cm^3
Molarity = $\frac{2 \text{ mol } NaHCO_3}{0.0778 \text{ L}}$
= 25.7 mol/L

Figure 15.5 | **The concentration of a substance in the solid state is a constant.** Doubling the number of moles also doubles the volume, but the *ratio* of moles to volume remains the same.

Similar reasoning shows that the concentration of Na_2CO_3 in pure solid Na_2CO_3 is a constant, too. This means that the equilibrium law now has three constants, K plus two of the concentration terms. It makes sense to combine all of the numerical constants together.

$$[H_2O(g)][CO_2(g)] = \frac{K[NaHCO_3(s)]^2}{[Na_2CO_3(s)]} = K_c$$

TOOLS

Equilibrium laws for heterogeneous reactions

> The equilibrium law for a heterogeneous reaction is written without concentration terms for pure solids or pure liquids.

Equilibrium constants that are given in tables represent all of the constants combined.[2]

---

[2] Thermodynamics handles heterogeneous equilibria in a more elegant way by expressing the mass action expression in terms of "effective concentrations," or **activities**. In doing this, thermodynamics *defines* the *activity* of any pure liquid or solid as equal to 1, which means terms involving such substances drop out of the mass action expression.

Example 15.4
Writing the Equilibrium Law for a Heterogeneous Reaction

The air pollutant sulfur dioxide can be removed from a gas mixture by passing the gases over calcium oxide. The equation is

$$CaO(s) + SO_2(g) \rightleftharpoons CaSO_3(s)$$

Write the equilibrium law for this reaction.

■ **Analysis:** For a heterogeneous equilibrium, we do not include pure solids or pure liquids in the mass action expression. Therefore, we exclude CaO and $CaSO_3$, and include only SO_2.

■ **Assembling the Tools:** Our tool is the method for constructing the equilibrium law.

■ **Solution:** The equilibrium law is simply

$$\frac{1}{[SO_2(g)]} = K_c$$

■ **Is the Answer Reasonable?** There's not much to check here except to review the reasoning, which appears to be okay.

Practice Exercises

15.9 | Write the equilibrium law for the following reaction. (*Hint:* Follow the reasoning above.)

$$NH_3(g) + HCl(g) \rightleftharpoons NH_4Cl(s)$$

15.10 | Write the equilibrium law for each of the following heterogeneous reactions.

(a) $2Hg(l) + Cl_2(g) \rightleftharpoons Hg_2Cl_2(s)$

(b) $Na(s) + H_2O(l) \rightleftharpoons NaOH(aq) + H_2(g)$

(c) Dissolving solid Ag_2CrO_4 in water: $Ag_2CrO_4(s) \rightleftharpoons 2Ag^+(aq) + CrO_4^{2-}(aq)$

(d) $CaCO_3(s) + H_2O(l) + CO_2(aq) \rightleftharpoons Ca^{2+}(aq) + 2HCO_3^-(aq)$

15.5 | Position of Equilibrium and the Equilibrium Constant

Whether we work with K_P or K_c, a bonus of always writing the mass action expression with the product concentrations in the numerator is that the size of the equilibrium constant gives us a measure of the **position of equilibrium** (how far the reaction proceeds toward completion when equilibrium is reached). For example, the reaction

$$2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(g)$$

has $K_c = 9.1 \times 10^{80}$ at 25 °C. For an equilibrium between these gases,

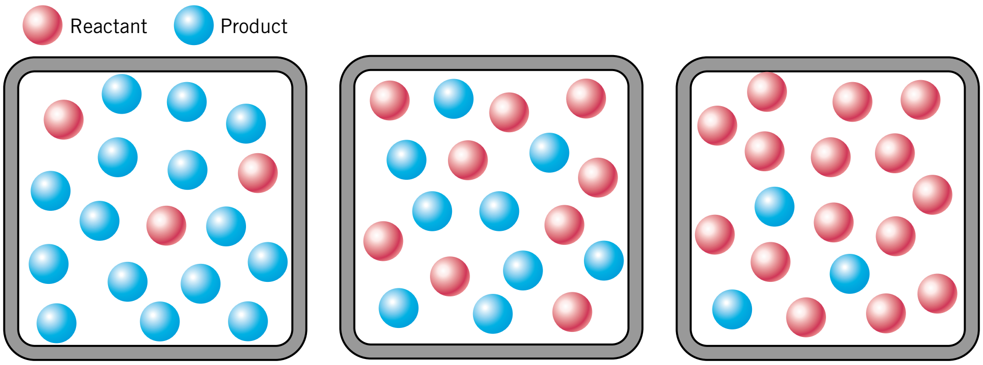
$$K_c = \frac{[H_2O]^2}{[H_2]^2[O_2]} = \frac{9.1 \times 10^{80}}{1}$$

By writing K_c as a fraction, $(9.1 \times 10^{80})/1$, we see that the numerator of the mass action expression must be enormous compared with the denominator, which means that the concentration of H_2O is huge compared with the concentrations of H_2 and O_2. At equilibrium, therefore, almost all of the hydrogen and oxygen atoms in the system are found in H_2O molecules and very few are present in H_2 and O_2. Thus, the enormous value of K_c tells us that *the position of equilibrium in this reaction lies far toward the right* and that the reaction of H_2 with O_2 goes essentially to completion.

■ Actually, you would need about 200,000 L of water vapor at 25 °C just to find one molecule of O_2 and two molecules of H_2.

The reaction between N_2 and O_2 to give NO,

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$$



$K >> 1$
The reaction proceeds far toward completion.

$K = 1$
Equilibrium is reached with equal concentrations of reactant and product.

$K << 1$
Hardly any reaction has occurred when equilibrium is reached.

Figure 15.6 | **The position of equilibrium and the magnitude of *K*.** Three views of an equilibrium mixture for reactions of the type

$$\text{reactant} \rightleftharpoons \text{product}$$

If $K >> 1$, the concentration of product is much larger than the concentration of reactant. The two concentrations are equal if $K = 1$, and the concentration of the product is much smaller than that of the reactant if $K << 1$.

has a very small equilibrium constant; $K_c = 4.8 \times 10^{-31}$ at 25 °C. The equilibrium law for the reaction is

$$\frac{[NO]^2}{[N_2][O_2]} = 4.8 \times 10^{-31} = \frac{4.8}{10^{31}}$$

Here the denominator is huge compared with the numerator, so the concentrations of N_2 and O_2 must be very much larger than the concentration of NO. This means that in a mixture of N_2 and O_2 at this temperature, the amount of NO that is formed is negligible. The reaction hardly proceeds at all toward completion before equilibrium is reached, and *the position of equilibrium lies far toward the left.*

■ In air at 25 °C, the equilibrium concentration of NO *should be* about 10^{-17} mol/L. It is usually higher because NO is formed in various reactions, such as those responsible for air pollution caused by automobiles.

The relationship between the equilibrium constant and the position of equilibrium can thus be summarized as follows (also see Figure 15.6):

When K is very large	The reaction proceeds far toward completion. The position of equilibrium lies far to the right, toward the products.
When $K \approx 1$	The concentrations of reactants and products are nearly the same at equilibrium. The position of equilibrium lies approximately midway between reactants and products.
When K is very small	Extremely small amounts of products are formed. The position of equilibrium lies far to the left, toward the reactants.

TOOLS

Significance of the magnitude of K

Notice that we have omitted the subscript for K in this summary. The same qualitative predictions about the extent of reaction apply whether we use K_P or K_c.

One of the ways that we can use equilibrium constants is to compare the extents to which two or more reactions proceed to completion. Take care in making such comparisons, however, because unless the values of K are greatly different, the comparison is valid only if both reactions have the same number of reactant and product molecules appearing in their balanced chemical equations.

Practice Exercises

15.11 | Suppose a mixture contained equal concentrations of H_2, Br_2, and HBr. Given that the reaction $H_2(g) + Br_2(g) \rightleftharpoons 2HBr(g)$ has $K_c = 1.4 \times 10^{-21}$, will the reaction proceed to the left or right in order to reach equilibrium? (*Hint:* In the mass action expression for this reaction, how should the size of the numerator compare with that of the denominator when the system reaches equilibrium?)

15.12 | Arrange the following reactions in order of their increasing tendency to proceed toward completion?

(a) $H_2(g) + Br_2(g) \rightleftharpoons 2HBr(g)$	$K_c = 1.4 \times 10^{-21}$
(b) $2NO(g) \rightleftharpoons N_2(g) + O_2(g)$	$K_c = 2.1 \times 10^{30}$
(c) $2BrCl \rightleftharpoons Br_2 + Cl_2$ (in CCl_4 solution)	$K_c = 0.145$

15.6 | Equilibrium and Le Châtelier's Principle

In Section 15.8 you will see that it is possible to perform calculations that tell us what the composition of an equilibrium system is. However, many times we really don't need to know exactly what the equilibrium concentrations are. Instead, we may want to know what actions we should take to control the relative amounts of the reactants or products at equilibrium. For instance, if we were designing gasoline engines, we would like to know what could be done to minimize the formation of nitrogen oxide pollutants. Or, if we were preparing ammonia, NH_3, by the reaction of N_2 with H_2, we might want to know how to maximize the yield of NH_3.

Le Châtelier's principle, introduced in Chapter 12, provides us with the means for making qualitative predictions about changes in chemical equilibria. It does this in much the same way that it allows us to predict the effects of outside influences on equilibria that involve physical changes, such as liquid–vapor equilibria. Recall that **Le Châtelier's principle** states that *if an outside influence upsets an equilibrium, the system undergoes a change in a direction that counteracts the disturbing influence and, if possible, returns the system to equilibrium*. Let's examine the kinds of "outside influences" that affect chemical equilibria.

Adding or Removing a Reactant or Product

■ Recall that the reaction quotient, *Q*, is the numerical value of the mass action expression.

When a system is at equilibrium, the reaction quotient Q is equal to K. For a homogeneous system, if we add or remove some of a reactant or product, the value of Q changes, which means it no longer equals K and the system is no longer at equilibrium. In other words, the equilibrium has been upset, and according to Le Châtelier's principle the system should change in a direction that opposes the disturbance we've introduced. If we've added a substance, the reaction should proceed in a direction to remove some of it; if we've removed a substance, the reaction should proceed in a direction to replace it.

As an example, let's study the following equilibrium between two *complex ions* of copper.

■ $Cu(H_2O)_4^{2+}$ and $CuCl_4^{2-}$ are called ***complex ions***. Some of the interesting properties of complex ions of metals are discussed in Chapter 22.

$$\underset{\text{blue}}{Cu(H_2O)_4^{2+}(aq)} + 4Cl^-(aq) \rightleftharpoons \underset{\text{yellow}}{CuCl_4^{2-}(aq)} + 4H_2O(l)$$

As noted, $Cu(H_2O)_4^{2+}$ is blue and $CuCl_4^{2-}$ is yellow. Mixtures of the two have an intermediate color and therefore appear blue-green, as illustrated in Figure 15.7, center.

Suppose we add chloride ion to an equilibrium mixture of these copper ions. The system can remove some Cl^- by reacting it with $Cu(H_2O)_4^{2+}$. This gives more $CuCl_4^{2-}$ (Figure 15.7, right), and we say that the equilibrium has "shifted to the right" or "shifted toward the products." In the new position of equilibrium, there is less $Cu(H_2O)_4^{2+}$ and more $CuCl_4^{2-}$ and uncombined H_2O. There is also more Cl^-, because not all that we add reacts. In other words, in this new position of equilibrium, *all* the concentrations have changed in a way that causes Q to become equal to K_c. Similarly, the position of equilibrium is shifted to the left when we add water to the mixture (Figure 15.7, left). The system is able to get rid of some of the H_2O by reaction with $CuCl_4^{2-}$, so more of the blue $Cu(H_2O)_4^{2+}$ is formed.

■ The reaction shifts in a direction that will remove a substance that's been added or replace a substance that's been removed.

If we were able to remove a reactant or product, the position of equilibrium would also be changed. For example, if we add Ag^+ to a solution that contains both copper ions in equilibrium, we see an enhancement of the blue color.

$$\begin{array}{c}\underset{\text{blue}}{Cu(H_2O)_4^{2+}(aq)} + 4Cl^-(aq) \rightleftharpoons \underset{\text{yellow}}{CuCl_4^{2-}(aq)} + 4H_2O \\ \Downarrow \\ Ag^+(aq) + Cl^-(aq) \rightleftharpoons AgCl(s)\end{array}$$

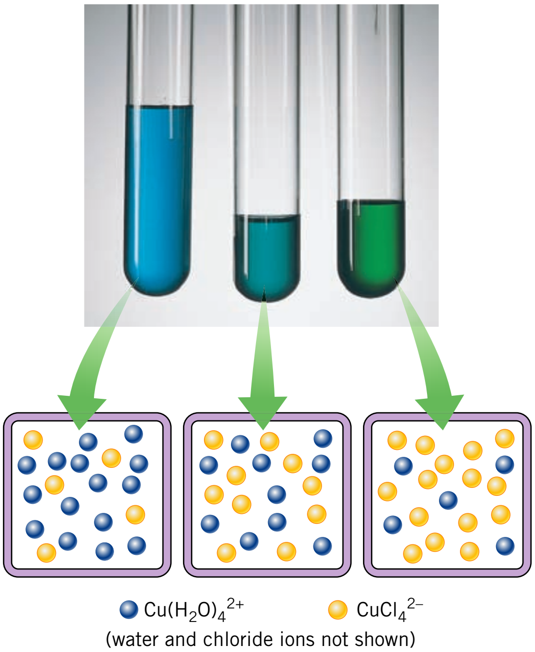


Figure 15.7 | **The effect of concentration changes on the position of equilibrium.** The solution in the center contains a mixture of blue $Cu(H_2O)_4^{2+}$ and yellow $CuCl_4^{2-}$, so it has a blue-green color. At the right, some of the same solution after the addition of concentrated HCl. It has a more pronounced green color because the equilibrium is shifted toward $CuCl_4^{2-}$. At the left is some of the original solution after the addition of water. It is blue because the equilibrium has shifted toward $Cu(H_2O)_4^{2+}$. *(Michael Watson)*

As the Ag^+ reacts with Cl^- to form insoluble AgCl in the second reaction, the equilibrium in the first reaction shifts to the left to replace some of the Cl^-, which also produces more blue $Cu(H_2O)_4^{2+}$. The position of equilibrium shifts to replace the substance that is removed.

> The position of equilibrium shifts in a way to remove reactants or products that have been added, or to replace reactants or products that have been removed.

TOOLS

Le Châtelier's principle; adding or removing a reactant or product

Changing the Volume of a Gaseous Equilibrium

Changing the volume of a mixture of reacting gases changes molar concentrations and partial pressures, so we would expect volume changes to have some effect on the position of equilibrium. Let's consider the equilibrium involved in the industrial synthesis of ammonia, which was described in the opening photo of this chapter and is the subject of *Chemistry Outside the Classroom 15.1*.

$$3H_2(g) + N_2(g) \rightleftharpoons 2NH_3(g)$$

If we reduce the volume of the reaction mixture, we cause the pressure to increase. The system can counteract the pressure increase if it is able to produce fewer molecules of gas, because fewer molecules exert a lower pressure. For the reaction above, forming more ammonia does just that. When the reaction proceeds to the right, two NH_3 molecules appear when four molecules (one N_2 and three H_2) disappear. Therefore, this equilibrium is shifted to the right when the volume of the reaction mixture is reduced.

Now let's look at the equilibrium

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

If this reaction proceeds in either direction, there is no change in the number of molecules of gas. This reaction, therefore, cannot respond to pressure changes, so changing the volume of the reaction vessel has virtually no effect on the equilibrium.

The simplest way to analyze the effects of a volume change on an equilibrium system involving gases is to count the number of molecules of *gaseous* substances on both sides of the equation.

CHEMISTRY OUTSIDE THE CLASSROOM | **15.1**

The Haber Process: Feeding Earth's Population

In the popular press, "chemistry" is often given a "bloody nose." Rarely is it mentioned that without the chemical industry, widespread famine would exist today across the world. This is because nearly one-third of the earth's human population is sustained by fertilizers generated from ammonia produced by the reaction of H_2 with N_2 in an industrial process known as the Haber process (also called the Haber–Bosch process).

At room temperature and pressure, nitrogen has little tendency to react with anything. The strong triple bond in the N_2 molecule causes any reaction that involves the breaking of the $N{\equiv}N$ bond to have a very high activation energy, which makes the reaction extremely slow. Making the reaction between H_2 and N_2 industrially viable requires extreme conditions of pressure and temperature. In the summer of 1909, Fritz Haber demonstrated how to overcome these obstacles, and Carl Bosch later scaled up the process to industrial size. Both Haber and Bosch were later awarded Nobel Prizes for their work.

In a modern ammonia synthesis plant, hydrogen is obtained from natural gas, which is composed chiefly of methane, CH_4. Methane is reacted with steam over a nickel oxide catalyst.

$$CH_4(g) + H_2O(g) \longrightarrow CO(g) + 3H_2(g)$$
$$CO(g) + H_2O(g) \longrightarrow CO_2(g) + H_2(g)$$

The net result is that methane and steam are converted to hydrogen gas and carbon dioxide. Nitrogen for the Haber process is obtained from air, where it is present at a level of 78%.

The final stage of the process is to combine hydrogen and nitrogen over an iron oxide catalyst.

$$3H_2(g) + N_2(g) \rightleftharpoons 2NH_3(g) \qquad \Delta H^\circ = -92.4 \text{ kJ mol}^{-1}$$

High pressures in the range of 150–250 atm are used to help force the position of equilibrium to the right. High temperatures (300–500 °C) are also used, even though they tend to shift the position of equilibrium away from ammonia. This is necessary to make the catalyst effective and make the reaction proceed at an acceptable rate. Under these conditions, one pass over the catalyst bed produces a yield of only about 15%, but the mixture is passed over multiple catalyst beds, with cooling between passes to remove NH_3. Any unreacted gases are recycled, so eventually a total yield of nearly 98% is achieved.

Ammonia itself can be used as a fertilizer by injecting it directly into the ground, where it is captured by moisture in the soil (Figure 1). The gas also serves as a raw material for the production of nitrates and nitrites, which can be isolated as potassium or ammonium salts. The latter are solids that can be incorporated with other necessary plant nutrients to produce more complete fertilizers.

Figure 1 A farmer operates machinery that injects ammonia gas directly into the soil, where it will act as a fertilizer. *Doug Martin/Photo Researchers*

TOOLS

Le Châtelier's principle; changing the volume of a gaseous equilibrium

Reducing the volume of a gaseous reaction mixture causes the position of equilibrium to shift in a direction that decreases the number of molecules of gas. No change in the equilibrium will occur if a volume change cannot affect the number of molecules of gas.

As a final note here, *moderate pressure changes have negligible effects on reactions involving only liquids or solids.* Substances in these states are virtually incompressible, and reactions involving them have no way to counteract pressure changes.

Changing the Temperature

To change the temperature of an equilibrium system, heat is either added or removed. For example, the decomposition of $N_2O_4(g)$ into $NO_2(g)$ discussed in Section 15.1 is endothermic in the forward direction, with $\Delta H^\circ = +57.9$ kJ.

$$N_2O_4(g) \rightleftharpoons 2NO_2(g) \qquad \Delta H^\circ = +57.9 \text{ kJ}$$

If we add heat to raise the temperature of the equilibrium mixture, the position of equilibrium will shift in the direction that absorbs heat. Because the reaction from left to right is endothermic, the position of equilibrium will shift to the right. This increases the concentration of NO_2 and decreases the concentration of N_2O_4.

Sometimes it's easier to analyze the effect if we include energy in the equation. For this reaction, heat is absorbed in the forward direction, so we include heat as a reactant.

$$\text{Heat} + N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

Adding a reactant drives the reaction in the forward direction, with heat behaving like any other reactant in this case.

Lowering the temperature by removing heat from an equilibrium system has the opposite effect from adding heat. Such a disturbance to the equilibrium promotes an exothermic change, which partially replaces the heat removed. In the preceding reaction, the reaction from right to left is exothermic, so removing heat from the system shifts the equilibrium position to the left. This causes the concentration of N_2O_4 to increase and the concentration of NO_2 to decrease.

> Increasing the temperature shifts a reaction in a direction that produces an endothermic (heat-absorbing) change.
>
> Decreasing the temperature shifts a reaction in a direction that produces an exothermic (heat-releasing) change.

TOOLS

Le Châtelier's principle; raising or lowering the temperature

This gives us a way to experimentally determine whether a reaction is exothermic or endothermic, without using a thermometer. Earlier we described the equilibrium involving complex ions of copper. The effect of temperature on this equilibrium is demonstrated in Figure 15.8. When the reaction mixture is heated, we see from the color change that the equilibrium shifts toward the products. Therefore, the reaction must be endothermic.

■ When heat is added to an equilibrium mixture, it is added to all of the substances present (reactants *and* products). As the system returns to equilibrium, the net reaction that occurs is the one that is endothermic.

Effect of Temperature Changes on *K* for a Reaction

Changes in concentrations or volume can shift the position of equilibrium, but *they do not change the equilibrium constant.* Changing the temperature, however, causes the position of equilibrium to shift because it changes the value of *K.* The enthalpy change of the reaction is the critical factor. Consider, for example, the equilibrium for the formation of ammonia.

■ Temperature is the only factor that can change *K* for a given reaction.

$$3H_2(g) + N_2(g) \rightleftharpoons 2NH_3(g) \qquad \Delta H^\circ = -46.19 \text{ kJ}$$

$$\frac{[NH_3]^2}{[H_2]^3[N_2]} = K_c$$

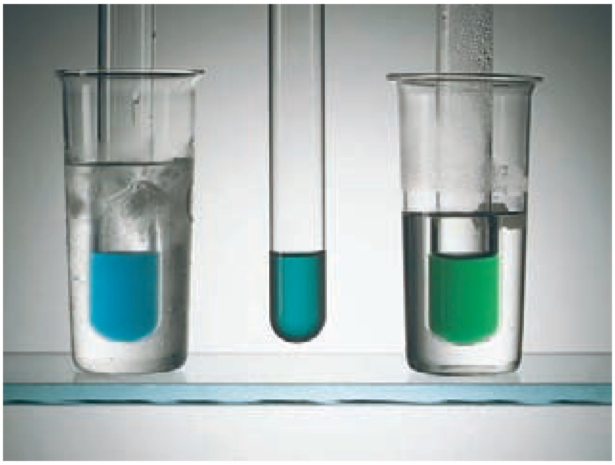

Figure 15.8 | **The effect of temperature on the equilibrium**

$$\mathbf{Cu(H_2O)_4^{2+} + 4Cl^- \rightleftharpoons CuCl_4^{2-} + 4H_2O}$$

In the center is an equilibrium mixture of the two complex ions. When the solution is cooled in ice (left), the equilibrium shifts toward the blue $Cu(H_2O)_4^{2+}$. When heated in boiling water (right), the equilibrium shifts toward $CuCl_4^{2-}$. This behavior indicates that the reaction is endothermic in the forward direction. *(Michael Watson)*

Because the reaction is exothermic, increasing the temperature shifts the equilibrium to the left. When equilibrium is restored, the concentration of NH_3 has decreased and the concentrations of N_2 and H_2 have increased. Therefore, the numerator of the mass action expression has become *smaller* and the denominator *larger*. This gives a smaller reaction quotient and therefore a smaller value of K_c.

■ We'll see how to quantitatively relate *K* and temperature in Chapter 19.

Le Châtelier's principle; changing temperature changes *K*

> Increasing the temperature of an exothermic reaction makes its equilibrium constant smaller.
>
> Increasing the temperature of an endothermic reaction makes its equilibrium constant larger.

Catalysts and the Position of Equilibrium

Recall that catalysts are substances that affect the speeds of chemical reactions without actually being used up. However, *catalysts do not affect the position of equilibrium in a system.* The catalyst's only effect is to bring the system to equilibrium faster.

■ Catalysts don't appear in the chemical equation for a reaction, so they don't appear in the mass action expression, either.

Pressure Changes Caused by Adding an Inert Gas at Constant Volume

A change in volume is not the only way to change the pressure in an equilibrium system of gaseous reactants and products. The pressure can also be changed by keeping the volume the same and adding another gas. If this gas cannot react with any of the gases already present (i.e., if the added gas is *inert* toward the substances in equilibrium), the concentrations and partial pressures of the reactants and products won't change. They will continue to satisfy the equilibrium law and the reaction quotient will continue to equal K_c, so there will be no change in the position of equilibrium.

Example 15.5

Application of Le Châtelier's Principle

The reaction $CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g)$ is endothermic with $K_c = 5.67$ at 1500 °C. How will the amount of $CO(g)$ at equilibrium be affected by (a) adding more $H_2O(g)$, (b) lowering the pressure by increasing the volume of the container, (c) raising the temperature of the reaction mixture, and (d) adding a catalyst to the system? Which of these will change the equilibrium constant and in which direction (increase or decrease) will K_c change?

■ **Analysis:** The problem asks us to predict the effects of various changes on the position of equilibrium, which is the clue that tells us the problem requires application of Le Châtelier's principle.

■ **Assembling the Tools:** Each of these kinds of disturbances was described in the preceding discussion, and the tools to deal with them are found in the statements in that discussion. We simply select the tool according to the type of disturbance involved.

■ **Solution:** (a) Adding H_2O will cause the equilibrium to shift to the right, in a direction that will consume some of the added H_2O. The amount of CO will increase.

(b) When the pressure in the system drops, the system responds by producing more molecules of gas, which will tend to raise the pressure and partially offset the change. If the reaction goes from left to right, we use up two molecules (one CH_4 and one H_2O) and form four molecules (one CO and three H_2). This yields a net increase in the number of molecules, so some CH_4 and H_2O react and the amount of CO at equilibrium will increase.

(c) Because the reaction is endothermic, we write the equation showing heat as a reactant:

$$\text{Heat} + CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g)$$

Raising the temperature is accomplished by adding heat, so the system will respond by absorbing heat. This means that the equilibrium will shift to the right and the amount of CO at equilibrium will increase.

(d) A catalyst causes a reaction to reach equilibrium more quickly, but it has no effect on the position of chemical equilibrium. Therefore, the amount of CO at equilibrium will not be affected.

Finally, the *only* change that alters K is the temperature change. Raising the temperature (adding heat) will increase K_c for this endothermic reaction.

■ **Are the Answers Reasonable?** There's not much we can do here other than review our reasoning. Doing so will reveal we've answered the questions correctly.

Practice Exercises

15.13 | Consider the equilibrium $PCl_5(g) + 4H_2O(g) \rightleftharpoons H_3PO_4(l) + 5HCl(g)$. How will the amount of H_3PO_4 at equilibrium be affected by decreasing the volume of the container holding the reaction mixture? (*Hint:* Notice that this is a heterogeneous equilibrium.)

15.14 | Consider the equilibrium $PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$, for which $\Delta H° = -88$ kJ. How will the amount of Cl_2 at equilibrium be affected by (a) adding PCl_3, (b) adding PCl_5, (c) raising the temperature, and (d) decreasing the volume of the container? How (if at all) will each of these changes affect K_P for the reaction?

15.7 | Calculating Equilibrium Constants

In Section 15.5 you learned that the magnitude of an equilibrium constant gives us some feel for the extent to which the reaction proceeds at equilibrium. Sometimes, however, it is necessary to have more than merely a qualitative knowledge of equilibrium concentrations. This requires that we be able to use the equilibrium law for purposes of calculation.

Equilibrium calculations for gaseous reactions can be performed using either K_P or K_c, but for reactions in solution we must use K_c. Whether we deal with concentrations or partial pressures, however, the same basic principles apply.

Overall, we can divide equilibrium calculations into two main categories:

1. Calculating equilibrium constants from known equilibrium concentrations or partial pressures.
2. Calculating one or more equilibrium concentrations or partial pressures using the known value of K_c or K_P.

In this section we will study how to calculate equilibrium constants. To keep things as simple as possible, we will stick to working problems involving K_c and molar concentrations.

One way to determine the value of K_c is to carry out the reaction, measure the concentrations of reactants and products after equilibrium has been reached, and then use the equilibrium values in the equilibrium law to compute K_c. As an example, let's look again at the decomposition of N_2O_4.

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

In Section 15.2, we saw that if 0.0350 mol of N_2O_4 is placed into a 1.00 liter flask at 25 °C, the concentrations of N_2O_4 and NO_2 at equilibrium are

$$[N_2O_4] = 0.0292 \text{ mol/L}$$
$$[NO_2] = 0.0116 \text{ mol/L}$$

To calculate K_c for the reaction, we substitute the equilibrium concentrations into the mass action expression of the equilibrium law.

$$\frac{[NO_2]^2}{[N_2O_4]} = K_c$$
$$\frac{(0.0116)^2}{(0.0292)} = K_c$$

Performing the arithmetic gives

$$K_c = 4.61 \times 10^{-3}$$

Concentration Tables

Concentration table

Only rarely are we given all the equilibrium concentrations required to calculate the equilibrium constant. Usually, we have information about the composition of a reaction mixture when it is first prepared, as well as some additional data that we can use to figure out what the equilibrium concentrations are. To help organize our thinking, our tool will be a **concentration table** that we will set up beneath the chemical equation. In this table we keep track of the concentrations of the substances involved in the reaction as it proceeds toward equilibrium. Normally the table has the same number of data columns as there are substances in the equilibrium equation. The table has three rows, which we label *Initial Concentrations, Changes in Concentrations*, and *Equilibrium Concentrations*. Entries in the table are either numbers with units of molar concentration (mol L^{-1}) or variables (e.g., x) that represent molar concentrations. Let's look at how the data for each row are obtained.

Initial Concentrations

The initial concentrations are those present in the reaction mixture when it's prepared; *we imagine that no reaction occurs until everything is mixed.* Often, the statement of a problem will give the initial molar concentrations, and these are then entered into the table under the appropriate formulas. In other cases, the mass or number of moles of reactants or products dissolved in a specified volume are given and we must then calculate the molar concentrations. *If the initial amount or concentration of a reactant or product is not mentioned in the problem, we will assume none was added to the reaction mixture initially, so its initial concentration is entered as zero.*

■ Remember, all entries in the concentration table must be molarities. If you use moles instead, you may end up with incorrect answers.

Changes in Concentrations

If the reaction mixture is not at equilibrium when it's prepared, the chemical reaction must occur (either to the left or right) to bring the system to equilibrium. When this happens, the concentrations change. We will use a positive sign to indicate that a concentration increases and a negative sign to show a decrease in concentration.

The changes in concentrations **always** *occur in the same ratio as the coefficients in the balanced equation.* For example, if we were dealing with the equilibrium

$$3H_2(g) + N_2(g) \rightleftharpoons 2NH_3(g)$$

and found that the $N_2(g)$ concentration decreases by 0.10 M during the approach to equilibrium, the entries in the "change" row would be as follows:

	$3H_2(g)$	+	$N_2(g)$	$\rightleftharpoons$	$2NH_3(g)$
Changes in Concentrations:	$-3 \times (0.10\ M)$		$-1 \times (0.10\ M)$		$+2 \times (0.10\ M)$
	↓		↓		↓
	$-0.30\ M$		$-0.10\ M$		$+0.20\ M$

In constructing the "change" row, *be sure that the reactant concentrations all change in the same direction and that the product concentrations all change in the opposite direction*. If the concentrations of the reactants decrease, all the entries for the reactants in the "change" row should have a minus sign, and all the entries for the products should be positive. In this example, N_2 reacts with H_2 (so their concentrations both decrease) and form NH_3 (so its concentration increases).

In Section 15.8, where we will be trying to find equilibrium concentrations from K_c and initial concentrations, our goal will be to find numerical values for the quantities in the change row. These quantities will be unknowns and will be represented symbolically by variables.

Equilibrium Concentrations

These are the concentrations of the reactants and products when the system finally reaches equilibrium. We obtain them by adding the changes in concentrations to the initial concentrations.

$$\begin{pmatrix}\text{initial}\\ \text{concentration}\end{pmatrix} + \begin{pmatrix}\text{change in}\\ \text{concentration}\end{pmatrix} = \begin{pmatrix}\text{equilibrium}\\ \text{concentration}\end{pmatrix}$$

The equilibrium concentrations are the only quantities that satisfy the equilibrium law. In this section we will use the numerical values in the last row to calculate K_c.

The concentration table is one of our most useful tools for analyzing and setting up equilibrium problems. As you will see, we will use it in almost every problem. The following example illustrates how we can use it in calculating an equilibrium constant.

Example 15.6

Calculating K_c from Equilibrium Concentrations

At a certain temperature, a mixture of H_2 and I_2 was prepared by placing 0.200 mol of H_2 and 0.200 mol of I_2 into a 2.00 liter flask. After a period of time the following equilibrium was established:

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

The purple color of the I_2 vapor was used to monitor the reaction, and from the decreased intensity of the purple color it was determined that, at equilibrium, the I_2 concentration had dropped to 0.020 mol L^{-1}. What is the value of K_c for this reaction at this temperature?

■ **Analysis:** The first step in *any* equilibrium problem is to write the balanced chemical equation and the related equilibrium law. The equation is already given, and the equilibrium law corresponding to it is

$$\frac{[HI]^2}{[H_2][I_2]} = K_c$$

To calculate the value of K_c we must substitute the *equilibrium concentrations* of H_2, I_2, and HI into the mass action expression. But what are they? We have been given only one directly, the value of $[I_2]$. To obtain the others, we have to do some chemical reasoning.

■ **Assembling the Tools:** The principal tool to solve this problem will be a concentration table, constructed following the procedure described previously. Once we've filled in the last row of the table, we can substitute the values for the equilibrium concentrations into the next tool, the equilibrium law, and calculate K_c. Because the table must contain molar concentrations, another tool we will apply is the definition of molarity.

■ **Solution:** The first step is to enter the data given in the statement of the problem. As noted above, the entries must be molar concentrations, but we've been given moles and the volume of the container. Therefore, for the initial concentrations we have to calculate the ratio of moles to liters for both the H_2 and I_2, (0.200 mol/2.00 L) = 0.100 *M*. Because no HI was placed into the reaction mixture, its initial concentration is set to zero. These quantities are shown in colored type in the first row. The problem statement also gives us the equilibrium concentration of I_2, so we enter this in the table in the last row (also shown in colored type). The values in regular type are then derived as described below.

	$H_2(g)$	+	$I_2(g)$	$\rightleftharpoons$	$2HI(g)$
Initial concentrations (*M*)	**0.100**		**0.100**		**0.000**
Changes in concentrations (*M*)	−0.080		−0.080		+2(0.080)
Equilibrium concentrations (*M*)	0.020		**0.020**		0.160

■ The changes in concentrations are controlled by the stoichiometry of the reaction. If we can find one of the changes, we can calculate the others from it.

Changes in Concentrations

We have been given both the initial and equilibrium concentrations of I_2, so by difference we can calculate the change for I_2 (−0.080 *M*). The other changes are then calculated from the mole ratios specified by the coefficients of the balanced equation. Because H_2 and I_2 have the same coefficients (i.e., 1), their changes are equal. The coefficient of HI is 2, so its change must be twice that of I_2. Reactant concentrations are decreasing, so their changes are negative; the product concentration increases, so its change is positive.

Equilibrium Concentrations

For H_2 and HI, we just add the change to the initial value.

The hard work has now been done. We substitute the equilibrium concentrations from the last row of the table into the mass action expression and calculate K_c.

$$K_c = \frac{(0.160)^2}{(0.020)(0.020)}$$
$$= 64$$

■ **Is the Answer Reasonable?** First, carefully examine the equilibrium law. As always, products must be placed in the numerator and reactants in the denominator. Be sure that each exponent corresponds to the correct coefficient in the balanced chemical equation.

Next, check the concentration table to be sure all entries are molar concentrations. Note that the initial concentration of HI is zero. The change for HI must be positive, because the HI concentration cannot become smaller than zero. The positive value in the table agrees with this assessment. Notice, also, that the changes for both reactants have the same sign, which is opposite that of the product. *This relationship among the signs of the changes is always true and serves as a useful check when you construct a concentration table.*

Finally, we can check to be sure we've entered each of the equilibrium concentrations into the mass action expression correctly. At this point we can be confident we've set up the problem correctly. To be sure of the answer, redo the calculation on your calculator.

Practice Exercises

15.15 | In a particular experiment, it was found that when $O_2(g)$ and $CO(g)$ were mixed and allowed to react according to the equation

$$2CO(g) + O_2(g) \rightleftharpoons 2CO_2(g)$$

the O_2 concentration had decreased by 0.030 mol L^{-1} when the reaction reached equilibrium. How had the concentrations of CO and CO_2 changed? (*Hint:* How are the changes in concentrations related to one another as the reaction approaches equilibrium?)

15.16 | An equilibrium was established for the reaction

$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g)$$

at 500 °C. (This is an industrially important reaction for the preparation of hydrogen.) At equilibrium, the following concentrations were found in the reaction vessel: $[CO] = 0.180\ M$, $[H_2O] = 0.0411\ M$, $[CO_2] = 0.150\ M$, and $[H_2] = 0.200\ M$. What is the value of K_c for this reaction?

15.17 | A student placed 0.200 mol of $PCl_3(g)$ and 0.100 mol of $Cl_2(g)$ into a 1.00 liter container at 250 °C. After the reaction

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$$

came to equilibrium it was found that the flask contained 0.120 mol of PCl_3.

(a) What were the initial concentrations of the reactants and product?
(b) By how much had the concentrations changed when the reaction reached equilibrium?
(c) What were the equilibrium concentrations?
(d) What is the value of K_c for this reaction at this temperature?

15.8 | Using Equilibrium Constants to Calculate Concentrations

In the simplest calculation of this type, all but one of the equilibrium concentrations are known, as illustrated in Example 15.7.

Example 15.7

Using K_c to Calculate Concentrations at Equilibrium

The reversible reaction

$$CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g)$$

has been used as a commercial source of hydrogen. At 1500 °C, $K_c = 5.67$ and an equilibrium mixture of these gases was found to have the following concentrations: $[CO] = 0.300\ M$, $[H_2] = 0.800\ M$, and $[CH_4] = 0.400\ M$. At 1500 °C, what was the equilibrium concentration of $H_2O(g)$ in the mixture?

■ **Analysis:** We have all of the equilibrium concentrations except one. Because the equilibrium concentrations are related to each other by the equilibrium law, we should be able to substitute values and solve for $[H_2O]$.

■ **Assembling the Tools:** In solving any equilibrium problem, the tools we need are the balanced chemical equation and the equilibrium law. We already have the equation, so we use it to write

$$K_c = \frac{[CO][H_2]^3}{[CH_4][H_2O]}$$

(By now you should be familiar with the procedure for doing this. If not, review Section 15.2.)

Solution: We substitute the values given in the statement of the problem into the equilibrium law and solve for the unknown quantity.

$$5.67 = \frac{(0.300)(0.800)^3}{(0.400)[H_2O]}$$

Solving for $[H_2O]$ gives

$$[H_2O] = \frac{(0.300)(0.800)^3}{(0.400)(5.67)} = \frac{0.154}{2.27} = 0.0678\ M$$

Is the Answer Reasonable? *We can always check problems of this kind by substituting all of the equilibrium concentrations into the mass action expression to see if the value of Q we get equals K_c.* Let's do this.

$$Q = \frac{[CO][H_2]^3}{[CH_4][H_2O]} = \frac{(0.300)(0.800)^3}{(0.400)(0.0678)} = 5.66$$

Rounding off the H_2O concentration caused a slight error, but Q is so close to K_c that we can be sure we've solved the problem correctly.

Practice Exercises

15.18 | The decomposition of N_2O_4 at 25 °C,

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

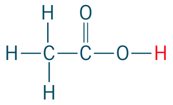
has $K_c = 4.61 \times 10^{-3}$. A 2.00 L vessel contained 0.0466 mol N_2O_4 at equilibrium. What was the concentration of NO_2 in the vessel? (*Hint:* What was the concentration of N_2O_4 in the container at equilibrium?)

15.19 | Ethyl ethanoate (commonly called ethyl acetate), $CH_3CO_2C_2H_5$, is an important solvent used in nail polish remover, lacquers, adhesives, the manufacture of plastics, and even as a food flavoring. It is produced from acetic acid and ethanol by the reaction

$$\underset{\substack{\text{ethanoic acid}\\\text{(acetic acid)}}}{CH_3CO_2H} + \underset{\text{ethanol}}{C_2H_5OH} \rightleftharpoons \underset{\substack{\text{ethyl ethanoate}\\\text{(ethyl acetate)}}}{CH_3CO_2C_2H_5} + H_2O$$

At 25 °C, $K_c = 4.10$ for this reaction. In a reaction mixture, the following equilibrium concentrations were observed: $[CH_3CO_2H] = 0.210\ M$, $[H_2O] = 0.00850\ M$, and $[CH_3CO_2C_2H_5] = 0.910\ M$. What was the concentration of C_2H_5OH in the mixture?

Recall that acetic acid has the structure



where the hydrogen released by ionization is indicated in red. The formula of the acid is written either as CH_3CO_2H (which emphasizes its molecular structure) or as $HC_2H_3O_2$ (which emphasizes that the acid is monoprotic).

Using K_c and Initial Concentrations

A more complex type of calculation involves the use of initial concentrations and K_c to compute equilibrium concentrations. Although some of these problems can be so complicated that a computer is needed to solve them, we can learn the general principles involved by working on simple calculations. Even these, however, require a little applied algebra. This is where the concentration table can be especially helpful.

Example 15.8

Using K_c to Calculate Equilibrium Concentrations

The reaction

$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g)$$

has $K_c = 4.06$ at 500 °C. If 0.100 mol of CO and 0.100 mol of $H_2O(g)$ are placed in a 1.00 liter reaction vessel at this temperature, what are the concentrations of the reactants and products when the system reaches equilibrium?

Analysis: The key to solving this kind of problem is recognizing that at equilibrium the mass action expression *must* equal K_c. We must find values for the concentrations that satisfy this condition. Although we aren't given any of the equilibrium values, we know that whatever they are, they are related to each other by the equilibrium law.

Assembling the Tools: Our tools in setting up the calculation will be the equilibrium law,

$$\frac{[CO_2][H_2]}{[CO][H_2O]} = 4.06 \qquad \text{(at equilibrium)}$$

and the concentration table. The problem gives us information about the initial concentrations, which we'll use to establish values for the first line of the table. If we knew how much the concentrations change, we could calculate the equilibrium concentrations. There are no data that let us calculate directly what any of the changes are, so we will represent them algebraically as unknowns. Combining the changes with the initial concentrations will give us algebraic expressions for the equilibrium concentrations. The relationship among the equilibrium concentrations is established by substituting them into the mass action expression.

■ The quantities representing the equilibrium concentrations must satisfy the equation given by the equilibrium law.

Solution: To build the table, we need quantities to enter into the "initial concentrations," "changes in concentrations," and "equilibrium concentrations" rows.

Initial Concentrations

The initial concentrations of CO and H_2O are each 0.100 mol/1.00 L = 0.100 *M*. Since no CO_2 or H_2 are initially placed into the reaction vessel, their initial concentrations both are zero. These are shown in red in the table.

Changes in Concentration

Some CO_2 and H_2 must form for the reaction to reach equilibrium. This also means that some CO and H_2O must react. But how much? If we knew the answer, we could calculate the equilibrium concentrations. Therefore, the changes in concentration are our unknown quantities.

Let us allow x to be equal to the number of moles per liter of CO that react. The change in the concentration of CO is then $-x$ (it is negative because the change decreases the CO concentration). Because CO and H_2O react in a 1:1 mole ratio, the change in the H_2O concentration is also $-x$. Since one mole each of CO_2 and H_2 are formed from one mole of CO, the CO_2 and H_2O concentrations each increase by x (their changes are $+x$). These quantities are shown in blue.

■ We could just as easily have chosen x to be the number of mol/L of H_2O that reacts or the number of mol/L of CO_2 or H_2 that forms. There's nothing special about having chosen CO to define x.

Equilibrium Concentrations

We obtain the equilibrium concentrations as

$$\begin{pmatrix}\text{equilibrium}\\ \text{concentration}\end{pmatrix} = \begin{pmatrix}\text{initial}\\ \text{concentration}\end{pmatrix} + \begin{pmatrix}\text{change in}\\ \text{concentration}\end{pmatrix}$$

Here is the completed concentration table.

	$CO(g)$	+	$H_2O(g)$	$\rightleftharpoons$	$CO_2(g)$	+	$H_2(g)$
Initial concentrations (*M*)	0.100		0.100		0.0		0.0
Changes in concentrations (*M*)	$-x$		$-x$		$+x$		$+x$
Equilibrium concentrations (*M*)	$0.100 - x$		$0.100 - x$		x		x

We know that the quantities in the last row must satisfy the equilibrium law, so we substitute them into the mass action expression and solve for x.

$$\frac{(x)(x)}{(0.100 - x)(0.100 - x)} = 4.06$$

which we can write as

$$\frac{x^2}{(0.100 - x)^2} = 4.06$$

In this problem we can solve the equation for x most easily by taking the square root of both sides.

$$\sqrt{\frac{x^2}{(0.100 - x)^2}} = \frac{x}{(0.100 - x)} = \sqrt{4.06} = 2.01$$

Clearing fractions gives

$$x = 2.01(0.100 - x)$$
$$x = 0.201 - 2.01x$$

Collecting terms in x gives

$$x + 2.01x = 0.201$$
$$3.01x = 0.201$$
$$x = 0.0668$$

Now that we know the value of x, we can calculate the equilibrium concentrations from the last row of the table.

$$[CO] = 0.100 - x = 0.100 - 0.0668 = 0.033\ M$$
$$[H_2O] = 0.100 - x = 0.100 - 0.0668 = 0.033\ M$$
$$[CO_2] = x = 0.0668\ M$$
$$[H_2] = x = 0.0668\ M$$

■ **Is the Answer Reasonable?** First, we should check to see that all equilibrium concentrations are positive numbers (which they must be because a negative concentration is meaningless). They are. As in the preceding example, we can check the answer by substituting the equilibrium concentrations we've found into the mass action expression and evaluate the reaction quotient.

$$Q = \frac{(0.0668)^2}{(0.033)^2} = 4.1$$

Once again, Q is quite close to K_c, so we can be confident our answers are correct.

Example 15.9
Using K_c to Calculate Equilibrium Concentrations

In the preceding example (Example 15.8) it was stated that the reaction

$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g)$$

has $K_c = 4.06$ at 500 °C. Suppose 0.0600 mol each of CO and H_2O are mixed with 0.100 mol each of CO_2 and H_2 in a 1.00 L reaction vessel. What will the concentrations of all of the substances be when the mixture reaches equilibrium at this temperature?

■ **Analysis:** We will proceed in much the same way as in Example 15.8. However, this time determining the algebraic signs of x will not be quite so simple because none of the initial concentrations is zero. The best way to determine the algebraic signs is to use the initial concentrations to calculate the initial reaction quotient. We can then compare Q to K_c, and by reasoning, figure out which way the reaction must proceed to make Q equal to K_c.

Assembling the Tools: The equilibrium law for the reaction is

$$\frac{[CO_2][H_2]}{[CO][H_2O]} = K_c$$

One of our tools will be the mass action expression, from which we can calculate the initial value of Q. Once we know in which direction the reaction must proceed to reach equilibrium, we can construct the concentration table.

Solution: First we use the initial concentrations, shown in the first row of the concentration table below, to determine the initial value of the reaction quotient.

$$Q_{\text{initial}} = \frac{(0.100)(0.100)}{(0.0600)(0.0600)} = 2.78 < K_c$$

As indicated, Q_{initial} is less than K_c, so the system is not at equilibrium. To reach equilibrium Q must become larger, which requires an increase in the concentrations of CO_2 and H_2 as the reaction proceeds. This means that for CO_2 and H_2, the change must be positive, and, for CO and H_2O, the change must be negative.

Here is the completed concentration table.

	$CO(g)$	+	$H_2O(g)$	$\rightleftharpoons$	$CO_2(g)$	+	$H_2(g)$
Initial concentrations (*M*)	0.0600		0.0600		0.100		0.100
Change in concentrations (*M*)	$-x$		$-x$		$+x$		$+x$
Equilibrium concentrations (*M*)	$0.0600 - x$		$0.0600 - x$		$0.100 + x$		$0.100 + x$

As before, we substitute equilibrium quantities into the mass action expression in the equilibrium law, which gives us

$$\frac{(0.100 + x)^2}{(0.0600 - x)^2} = 4.06$$

Taking the square root of both sides yields

$$\frac{0.100 + x}{0.0600 - x} = 2.01$$

To solve for x we first multiply each side by $(0.0600 - x)$ to obtain

$$0.100 + x = 2.01(0.0600 - x)$$
$$0.100 + x = 0.121 - 2.01x$$

Collecting terms in x on one side and the constants on the other gives

$$x + 2.01x = 0.121 - 0.100$$
$$3.01x = 0.021$$
$$x = 0.0070$$

Now we can calculate the equilibrium concentrations:

$$[CO] = [H_2O] = (0.0600 - x) = 0.0600 - 0.0070 = 0.0530\ M$$
$$[CO_2] = [H_2] = (0.100 + x) = 0.100 + 0.0070 = 0.107\ M$$

Is the Answer Reasonable? As a check, let's evaluate the reaction quotient using the calculated equilibrium concentrations.

$$Q = \frac{(0.107)^2}{(0.0530)^2} = 4.08$$

This is acceptably close to the value of K_c. (That it is not *exactly* equal to K_c is because of the rounding of answers during the calculations.)

In each of the preceding two examples, we were able to simplify the solution by taking the square root of both sides of the algebraic equation obtained by substituting equilibrium concentrations into the mass action expression. Such simplifications are not always possible, however, as illustrated in the next example.

Example 15.10

Using K_c to Calculate Equilibrium Concentrations

At a certain temperature, $K_c = 4.50$ for the reaction

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

If 0.300 mol of N_2O_4 is placed into a 2.00 L container at this temperature, what will be the equilibrium concentrations of both gases?

■ **Analysis:** As in Example 15.9, we will use the fact that at equilibrium the mass action expression must be equal to K_c. Because neither of the equilibrium concentrations are given, we will have to find algebraic expressions for the equilibrium concentrations and substitute them into the mass action expression.

■ **Assembling the Tools:** As usual, our principal tools will be the equilibrium law,

$$\frac{[NO_2]^2}{[N_2O_4]} = 4.50$$

and the concentration table for the reaction. We also have to use the definition of molarity to calculate the initial molar concentration of N_2O_4 from the data given in the problem.

■ **Solution:** The first step is constructing the concentration table.

Initial Concentrations

The initial concentration of N_2O_4 is 0.300 mol/2.00 L = 0.150 *M*. Since no NO_2 was placed in the reaction vessel, its initial concentration is 0.000 *M*.

Changes in Concentrations

■ Any time an initial concentration equals zero, we know it must change in a positive direction. It can't become less than zero.

There is no NO_2 in the reaction mixture, so we know its concentration must increase. This means the N_2O_4 concentration must decrease as some of the NO_2 is formed. Let's allow x to be the number of moles per liter of N_2O_4 that reacts, so the change in the N_2O_4 concentration is $-x$. Because of the stoichiometry of the reaction, the NO_2 concentration must increase by $2x$, so its change in concentration is $+2x$.

Equilibrium Concentrations

As before, we add the change to the initial concentration in each column to obtain expressions for the equilibrium concentrations.

■ In problems where the changes in concentrations are unknown, we can let the coefficients of *x* be the same as the coefficients in the balanced equation. This ensures they are in the correct ratio.

Here is the completed concentration table.

	$N_2O_4(g)$	$\rightleftharpoons$	$2NO_2(g)$
Initial concentrations (*M*)	0.150		0.000
Changes in concentrations (*M*)	$-x$		$+2x$
Equilibrium concentrations (*M*)	$0.150 - x$		$2x$

To obtain the solution, we substitute the equilibrium quantities into the mass action expression.

$$\frac{(2x)^2}{(0.150 - x)} = 4.50$$

or

$$\frac{4x^2}{(0.150 - x)} = 4.50 \qquad \textbf{(15.11)}$$

This time the left side of the equation is not a perfect square, so we cannot just take the square root of both sides as in Examples 15.8 and 15.9. However, because the equation involves terms in x^2, x, and a constant, we can use the quadratic formula. Recall that for a quadratic equation of the form

$$ax^2 + bx + c = 0$$
$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Expanding Equation 15.11 gives

$$4x^2 = 4.50\,(0.150 - x)$$
$$4x^2 = 0.675 - 4.50x$$

Arranging terms in the standard order gives

$$4x^2 + 4.50x - 0.675 = 0$$

Therefore, the quantities we will substitute into the quadratic formula are as follows: $a = 4$, $b = 4.50$, and $c = -0.675$. Making these substitutions gives

$$\begin{aligned} x &= \frac{-4.50 \pm \sqrt{(4.50)^2 - 4(4)(-0.675)}}{2(4)} \\ &= \frac{-4.50 \pm \sqrt{31.05}}{8} \\ &= \frac{-4.50 \pm 5.57}{8} \end{aligned}$$

Because of the ± term, there are two values of x that satisfy the equation, $x = 0.134$ and $x = -1.26$. However, only the first value, $x = 0.134$, makes any sense chemically, as described below. Using $x = 0.134$, the equilibrium concentrations are

$$[N_2O_4] = 0.150 - 0.134 = 0.016\ M$$
$$[NO_2] = 2(0.134) = 0.268\ M$$

Notice that if we had used the negative root, -1.26, the equilibrium concentration of NO_2 would be negative. Negative concentrations are impossible, so $x = -1.26$ is not acceptable *for chemical reasons*. In general, whenever you use the quadratic equation in a chemical calculation, one root will be satisfactory and the other will lead to answers that are nonsense.

■ **Is the Answer Reasonable?** Once again, we can evaluate the reaction quotient using the calculated equilibrium values. When we do this, we obtain $Q = 4.49$, which is acceptably close to the value of K_c given.

Practice Exercises

15.20 | During an experiment, 0.200 mol of H_2 and 0.200 mol of I_2 were placed into a 1.00 liter vessel where the reaction

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

came to equilibrium. For this reaction, $K_c = 49.5$ at the temperature of the experiment. What were the equilibrium concentrations of H_2, I_2, and HI?

15.21 | In an experiment, 0.200 mol H_2 and 0.100 mol I_2 were placed in a 1.00 L vessel where the following equilibrium was established:

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

For this reaction, $K_c = 49.5$ at the temperature of the experiment. What were the equilibrium concentrations of H_2, I_2, and HI?

Equilibrium problems can be much more complex than the ones we have just discussed. However, sometimes you can make assumptions that simplify the problem so that an approximate solution can be obtained, as described next.

Calculations when K_c Is Very Small

Many chemical reactions have equilibrium constants that are either very large or very small. For example, most weak acids have very small values for K_c. Therefore, only very tiny amounts of products form when these weak acids react with water.

When the K_c for a reaction is very small, the position of equilibrium lies far to the left, toward the reactants. Usually this permits us to simplify the calculations considerably, as shown in Example 15.11.

Example 15.11

Simplifying Equilibrium Calculations for Reactions with a Small K_c

Hydrogen, a potential fuel, is found in great abundance in water. Before the hydrogen can be used as a fuel, however, it must be separated from the oxygen; the water must be split into H_2 and O_2. One possibility is thermal decomposition, but this requires very high temperatures. Even at 1000 °C, $K_c = 7.3 \times 10^{-18}$ for the reaction

$$2H_2O(g) \rightleftharpoons 2H_2(g) + O_2(g)$$

If at 1000 °C the H_2O concentration in a reaction vessel is set initially at 0.100 *M*, what will the H_2 concentration be when the reaction reaches equilibrium?

■ **Analysis:** As in earlier problems of this type, we can anticipate that we will have to solve an algebraic equation to obtain the equilibrium concentrations, none of which are given in the problem. We will follow that approach and see where it leads us.

■ **Assembling the Tools:** One tool we will definitely need is the equilibrium law:

$$\frac{[H_2]^2[O_2]}{[H_2O]^2} = 7.3 \times 10^{-18}$$

Another will be the concentration table.

■ **Solution:** The first step will be to construct the concentration table. The changes in concentrations are unknown and will be represented by expressions that contain the unknown quantity *x*.

Initial Concentrations

The initial concentration of H_2O is 0.100 *M*; those of H_2 and O_2 are both 0.0 *M*.

Changes in Concentrations

We know the changes must be in the same ratio as the coefficients in the balanced equation, so we place *x*'s in this row with coefficients equal to those in the chemical equation. Because there are no products present initially, their changes must be positive and the change for the water must be negative.

The complete concentration table is

	$2H_2O(g)$	$\rightleftharpoons$	$2H_2(g)$	+	$O_2(g)$
Initial concentrations (*M*)	0.100		0.0		0.0
Changes in concentrations (*M*)	$-2x$		$+2x$		$+x$
Equilibrium concentrations (*M*)	$0.100 - 2x$		$2x$		x

Next, we substitute the equilibrium quantities from the last row into the mass action expression.

$$\frac{(2x)^2 x}{(0.100 - 2x)^2} = 7.3 \times 10^{-18}$$

or

$$\frac{4x^3}{(0.100 - 2x)^2} = 7.3 \times 10^{-18}$$

■ $(2x)^2 x = (4x^2)x = 4x^3$

This is a *cubic equation* (one term involves x^3) and can be rather difficult to solve unless we can simplify it. In this instance we are able to simplify because the very small value of K_c tells us that hardly any of the H_2O will decompose. Whatever the actual value of *x*, we know *in advance* that it is going to be very small. This means that 2*x* will also be very small, so when this tiny value is subtracted from 0.100, the result will still be very, very close to 0.100. We will make the assumption, then, that the term in the denominator will be essentially unchanged from 0.100 by subtracting 2*x* from it; that is, we will assume that $0.100 - 2x \approx 0.100$.

■ Even before we solve the problem, we know that hardly any H_2 and O_2 will be formed, because K_c is so small.

This assumption greatly simplifies the math. We now have

$$\frac{4x^3}{(0.100 - 2x)^2} \approx \frac{4x^3}{(0.100)^2} = 7.3 \times 10^{-18}$$

$$\begin{aligned} 4x^3 &= (0.0100)(7.3 \times 10^{-18}) = 7.3 \times 10^{-20} \\ x^3 &= 1.8 \times 10^{-20} \\ x &= \sqrt[3]{1.8 \times 10^{-20}} \\ &= 2.6 \times 10^{-7} \end{aligned}$$

Notice that the value of *x* that we've obtained is indeed very small. If we double it and subtract the answer from 0.100, we still get 0.100 when we round to the correct number of significant figures (the third decimal place).

$$\begin{aligned} 0.100 - 2x = 0.100 - 2(2.6 \times 10^{-7}) &= 0.09999948 \\ &= 0.100 \qquad \text{(rounded correctly)} \end{aligned}$$

■ Always be sure to check your assumptions when solving a problem of this kind.

This check verifies that our assumption was valid. Finally, we have to obtain the H_2 concentration. Our table gives

$$[H_2] = 2x$$

Therefore,

$$[H_2] = 2(2.6 \times 10^{-7}) = 5.2 \times 10^{-7}\ M$$

Is the Answer Reasonable? The equilibrium constant is very small for this reaction (7.3×10^{-18}), so we expect the amount of product at equilibrium to be small as well. The very low concentration of H_2 seems reasonable. The value of x was positive, which means that there was a decrease in reactant concentrations and an increase in product concentrations as we would expect if only reactants were originally present. Finally, we can check the calculation by seeing if the reaction quotient is equal to the equilibrium constant:

$$Q = \frac{[H_2]^2[O_2]}{[H_2O]^2} = \frac{(5.2 \times 10^{-7})^2(2.6 \times 10^{-7})}{0.100^2} = 7.0 \times 10^{-18}$$

which differs from the original equilibrium constant only because the value of x was rounded off when we took the cube root.

Situations that Suggest Simplification of the Math Will Work

When the value of K_c or K_P is very small, the position of equilibrium lies far to the left, very near the reactants. This means that if we start with just reactants, the concentrations will hardly change. Under these conditions, the simplifying assumption made in Example 15.11 is valid because the small change in the reactant concentration, x, is subtracted from a much larger value. We could also have neglected x (or $2x$) if it were a very small number that was being added to a much larger one. Remember that you can only neglect an x that's *added* or *subtracted*; you can never drop an x that occurs as a multiplying or dividing factor. Some examples are

Simplifications in equilibrium calculations

$$x(0.100 - x)$$

You would never be justified in neglecting this x.

You are justified in neglecting this x, if x is small compared to 0.100.

$$\frac{(0.100 + x)}{x}$$

As a rule of thumb, you can expect that these simplifying assumptions will be valid if the concentration from which x is subtracted, or to which x is added, is at least 1000 times greater than K. For instance, in the preceding example, $2x$ was subtracted from 0.100. Since 0.100 is much larger than $1000 \times (7.3 \times 10^{-18})$ we expect the assumption $0.100 - 2x \approx 0.100$ to be valid. However, even though the simplifying assumption is *expected* to be valid, always check to see if it really is after finishing the calculation. If the assumption proves invalid, then some other way to solve the algebra must be found.

Practice Exercises

15.22 | At 25 °C, the reaction $2NH_3(g) \rightleftharpoons N_2(g) + 3H_2(g)$ has $K_c = 2.3 \times 10^{-9}$. If 0.041 mol NH_3 is placed in a 1.00 L container, what will the concentrations of N_2 and H_2 be when equilibrium is established? (*Hint:* Review the math below the concentration table in Example 15.11.)

15.23 | In air at 25 °C and 1.00 atm, the N_2 concentration is 0.033 *M* and the O_2 concentration is 0.00810 *M*. The reaction

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$$

has $K_c = 4.8 \times 10^{-31}$ at 25 °C. Taking the N_2 and O_2 concentrations given above as initial values, calculate the equilibrium NO concentration that should exist in our atmosphere from this reaction at 25 °C.

Analyzing and Solving Multi-Concept Problems

The reaction

$$2\mathrm{NO}(g) + \mathrm{O_2}(g) \rightleftharpoons 2\mathrm{NO_2}(g)$$

has $K_P = 1.65 \times 10^{11}$ at 25 °C. Suppose a mixture of the reactants is prepared at 25 °C by transferring 1.15 g of NO and 645 mL of O_2 measured at 33 °C and 800 torr into a 1.00 L vessel. When the mixture comes to equilibrium, what will be the concentrations of each of the three gases?

■ **Analysis** As with all equilibrium problems, we are going to work with the equilibrium law. For this gaseous reaction, we can write this as

$$\frac{[\mathrm{NO_2}]^2}{[\mathrm{NO}]^2[\mathrm{O_2}]} = K_c \qquad \text{or} \qquad \frac{P^2_{\mathrm{NO_2}}}{P^2_{\mathrm{NO}}P_{\mathrm{O_2}}} = K_P$$

We've been given K_P, but we know we can convert this to K_c. This was covered in Section 15.3. (Although we could work with K_P, this problem will be easier if we use K_c instead, because we're looking for equilibrium concentrations.)

Before we can construct the concentration table, we need the initial concentrations of the reactants. For NO, we have to convert grams to moles, which you learned to do in Chapter 4. For O_2, we must use the P, V, T data to find moles of O_2.

■ **Assembling the Tools** To find K_c, we have to use Equation 15.9, $K_P = K_c(RT)^{\Delta n_g}$. Solving for K_c gives

$$K_c = \frac{K_P}{(RT)^{\Delta n_g}} = K_P(RT)^{-\Delta n_g} \qquad \textbf{(15.12)}$$

Remember that $R = 0.0821$ L atm mol^{-1} K^{-1} and T is the Kelvin temperature.

To calculate the moles of NO placed in the reaction vessel, our tool is the molar mass of NO, which is 30.01 g mol^{-1}. To find moles of O_2, the tool is the ideal gas law, which we solve for $n_{\mathrm{O_2}}$,

$$n_{\mathrm{O_2}} = \frac{PV}{RT}$$

The definition of molarity provides the tool to calculate the molarity of each reactant.

■ **Solution** First we calculate K_c. Taking coefficients to represent moles, the reaction has two moles of gaseous products and three moles of gaseous reactants. Therefore, $\Delta n_g = -1$. Substituting values into Equation 15.12 gives

$$K_c = 1.65 \times 10^{11}\,[(0.0821 \text{ L atm mol}^{-1}\text{ K}^{-1}) \times (298 \text{ K})]^{-(-1)}$$
$$= 4.04 \times 10^{12}$$

Next, we calculate initial moles of each reactant.

Moles of NO

$$1.15 \text{ g NO} \times \frac{1 \text{ mol NO}}{30.01 \text{ g NO}} = 0.0383 \text{ mol NO}$$

Moles of O_2

$$n_{\mathrm{O_2}} = \frac{PV}{RT} = \frac{\left(\dfrac{800 \text{ torr}}{760 \text{ torr/atm}}\right) \times 0.645 \text{ L}}{(0.0821 \text{ L atm mol}^{-1}\text{ K}^{-1}) \times (298 \text{ K})}$$
$$= 0.0278 \text{ mol } \mathrm{O_2}$$

Both reactants are in the 1.00 L vessel, so their initial concentrations are [NO] = 0.0383 M and $[\mathrm{O_2}]$ = 0.0278 M. No NO_2 was placed in the vessel, so its initial concentration is zero. Here's the concentration table, assembled in the usual way.

	$2\mathrm{NO}(g)$	+	$\mathrm{O_2}(g)$	$\rightleftharpoons$	$2\mathrm{NO_2}(g)$
Initial concentrations (M)	0.0383		0.0278		0.000
Changes in concentrations (M)	$-2x$		$-x$		$+2x$
Equilibrium concentrations (M)	$0.0383 - 2x$		$0.0278 - x$		$2x$

Substituting equilibrium quantities into the equilibrium law gives

$$K_c = 4.04 \times 10^{12} = \frac{(2x)^2}{(0.0383 - 2x)^2(0.0278 - x)}$$

We might be tempted to assume that x (or $2x$) is negligibly small and can be dropped, which would make the algebra manageable. However, this isn't going to work here. The very large value of K_c tells us this reaction proceeds far toward completion, so almost all of at least one of the reactants will be consumed. *This means the changes in concentration are not small and can't be ignored.* So, the question is, can we reshape the problem to make it possible to solve it?

■ If you drop $2x$ and x in the terms in the denominator and then solve for x, you get $x = 6.4 \times 10^3$, a number that is certainly not small compared with 0.0383 or 0.0278.

Recasting the Problem

■ **Analysis** The algebra will be manageable if we can start the calculation with the system very close to equilibrium. In this reaction the position of equilibrium lies far to the right, as indicated by the value of K_c. Because the same equilibrium concentrations are reached regardless of whether we approach equilibrium from the left or the right, we are going to assume equilibrium in this system is reached in two steps. Step 1 will involve the complete reaction of the initial NO and O_2 to give NO_2. This is actually a limiting reactant problem. Step 2 will involve approaching equilibrium from the right. This will require that we rework the concentration table starting from the product side.

STEP 1

Assembling the Tools The tool is the method of working limiting reactant problems, which you learned in Chapter 4.

Solution We start with 0.0383 mol NO and 0.0278 mol O_2. If all the NO were to react, it would require only 0.0192 mol O_2,

$$0.0383 \text{ mol NO} \times \frac{1 \text{ mol } O_2}{2 \text{ mol NO}} = 0.0192 \text{ mol } O_2$$

Therefore, O_2 is in excess and NO is limiting. Based on the coefficients in the equation, if all the NO reacts, it will form 0.0383 mol NO_2 and the amount of O_2 remaining will be (0.0278 mol − 0.0192 mol) = 0.0086 mol.

STEP 2

Assembling the Tools The tools will be the same as those we tried initially when we attempted to solve the problem.

Solution Here are our new initial starting conditions:

$[NO] = 0.000\ M$ (We've assumed all initially present reacted.)
$[O_2] = 0.0086\ M$
$[NO_2] = 0.0383\ M$

The new concentration table is shown below. Notice that the signs have changed for the "changes in concentration" row. This reflects that we are now starting at the product side and that the reaction that's occurring is the one from right to left.

	$2NO(g)$ +	$O_2(g)$ $\rightleftharpoons$	$2NO_2(g)$
Initial concentrations (*M*)	0.000	0.0086	0.0383
Changes in concentrations (*M*)	$+2x$	$+x$	$-2x$
Equilibrium concentrations (*M*)	$2x$	$0.0086 + x$	$0.0383 - 2x$

Substituting values from the last row into the mass action expression gives

$$K_c = 4.04 \times 10^{12} = \frac{(0.0383 - 2x)^2}{(2x)^2(0.0086 + x)}$$

We know that, by starting at the product side, we are very close to equilibrium and therefore x and $2x$ are going to be small compared to the initial concentrations, so we feel safe in neglecting them. This gives

$$K_c = 4.04 \times 10^{12} \approx \frac{(0.0383)^2}{(4x^2)(0.0086)}$$

This can be solved for x to give $x = 1.03 \times 10^{-7}$. Using the quantities in the last row of the concentration table above, the equilibrium concentrations are as follows:

$[NO] = 2 \times (1.03 \times 10^{-7}) = 2.06 \times 10^{-7}\ M$
$[O_2] = (0.0086 + 1.03 \times 10^{-7}) = 0.0086\ M$ (correctly rounded)
$[NO_2] = [0.0383 - 2 \times (1.03 \times 10^{-7})] = 0.0383\ M$ (correctly rounded)

Are the Answers Reasonable? First, notice that after recasting the problem, we are justified in making the simplifying assumptions that made the mathematical equation easily solvable. We can also check the answers by substituting them into the mass action expression.

$$Q = \frac{(0.0383)^2}{(2.06 \times 10^{-7})^2(0.0086)} = 4.02 \times 10^{12} = K_c$$

The answers we've obtained satisfy the equilibrium law, so we can be confident they are correct.

Summary

Dynamic Equilibrium. When the forward and reverse reactions in a chemical system occur at equal rates, a dynamic equilibrium exists and the concentrations of the reactants and products remain constant. For a given overall chemical composition, the amounts of reactants and products that are present at equilibrium are the same regardless of whether the equilibrium is approached from the direction of pure "reactants," pure "products," or any mixture of them. (In a chemical equilibrium, the terms *reactants* and *products* do not have the usual significance because the reaction is proceeding in both directions simultaneously. Instead, we use *reactants* and *products* simply to identify the substances on the left- and right-hand sides, respectively, of the equation for the equilibrium.)

The Equilibrium Law. The **mass action expression** is a fraction. The concentrations of the products, raised to powers equal to their coefficients in the chemical equation for a **homogeneous equilibrium**, are multiplied together in the numerator. The denominator is constructed in the same way from the concentrations of the reactants raised to powers equal to their coefficients. The numerical value of the mass action expression is the **reaction quotient, Q**. At equilibrium, the reaction quotient is equal to the **equilibrium constant, K_c**. If partial pressures of gases are used in the mass action expression, **K_P** is obtained. The magnitude of the equilibrium constant is roughly proportional to the extent to which the reaction proceeds to completion when equilibrium is reached. Equilibrium equations can be manipulated by multiplying the coefficients by a common factor, changing the direction of the reaction, and by adding two or more equilibria. The rules given in the description of the *Tools for Problem Solving* below apply.

Relating K_P to K_c. The values of K_P and K_c are only equal if the same number of moles of gas are represented on both sides of the chemical equation. When the number of moles of gas are different, K_P is related to K_c by the equation $K_\mathrm{P} = K_\mathrm{c}(RT)^{\Delta n_\mathrm{g}}$. Remember to use $R = 0.0821$ L atm mol^{-1} K^{-1} and $T =$ absolute temperature. Also, be careful to calculate Δn_g as the difference between the number of moles of *gaseous* products and the number of moles of *gaseous* reactants in the balanced equation.

Heterogeneous Equilibria. An equilibrium involving substances in more than one phase is a **heterogeneous equilibrium**. The mass action expression for a heterogeneous equilibrium omits concentration terms for pure liquids and/or pure solids.

Le Châtelier's Principle. This principle states that *when an equilibrium is upset by some disturbance, a chemical change occurs in a direction that opposes the disturbing influence and brings the system to equilibrium again.* Adding a reactant or a product causes a reaction to occur that uses up part of what has been added. Removing a reactant or a product causes a reaction that replaces part of what has been removed. Increasing the pressure (by reducing the volume) drives a reaction in the direction of the fewer number of moles of gas. Altering the pressure on an equilibrium system involving only solids and liquids has virtually no effect on the position of equilibrium. Raising the temperature causes an equilibrium to shift in an endothermic direction. The value of K increases with increasing temperature for reactions that are endothermic in the forward direction. A change in temperature is the only factor that changes K. Addition of a catalyst or an inert gas has no effect on an equilibrium.

Equilibrium Calculations. The initial concentrations in a chemical system are controlled by the person who combines the chemicals at the start of the reaction. The changes in concentration are determined by the stoichiometry of the reaction. Only equilibrium concentrations satisfy the equilibrium law. When these are used, the value of the mass action expression, Q, is equal to K_c. When a change in concentration is expected to be very small compared to the initial concentration, the change may be neglected and the algebraic equation derived from the equilibrium law can be simplified. In general, this simplification is valid if the initial concentration is at least 1000 times larger than K.

Tools for Problem Solving The following tools related to solving chemical equilibria problems were introduced in this chapter.

The approach to equilibrium (page 698)

There are times (such as in *Analyzing and Solving Multi-Concept Problems,* page 729) when it is very helpful to remember that the same equilibrium composition is reached regardless of whether it is approached from the reactants or from the products. When K_c or K_P is very large, equilibrium problems can be greatly simplified if we first imagine the reaction going to completion (converting all the reactants to products) and then approaching the equilibrium from the direction of the products.

Requirement for equilibrium (page 700)

For a system to be at equilibrium, the numerical value of Q must equal the equilibrium constant. Use this tool to determine whether a system is at equilibrium when you have a way to calculate Q. By comparing Q with K, you can determine the direction the reaction must proceed to reach equilibrium.

The equilibrium law (page 701)

To solve most chemical equilibrium problems we need the equation for the equilibrium and the equilibrium law. Knowing how to construct the equilibrium law from the chemical equation is an essential tool for dealing with such problems. For a homogeneous reaction, an equation of the form

$$dD + eE \rightleftharpoons fF + gG$$

has the equilibrium law

$$\frac{[F]^f[G]^g}{[D]^d[E]^e} = K_c$$

Remember that for gaseous reactions, partial pressures can be used in place of concentrations, in which case the mass action expression equals K_P. In general, K_P does not equal K_c.

Manipulating equilibrium equations (pages 702 and 703)

There are occasions when it is necessary to modify an equation for an equilibrium, or to combine two or more chemical equilibria. The tools discussed here are used to obtain the new equilibrium constants for the new equations.

- When two equations are added, we multiply their *K*s to obtain the new *K*.
- When an equation is multiplied by a factor *n* to obtain a new equation, we raise its *K* to the power *n* to obtain the *K* for the new equation.
- When an equation is reversed, we take the reciprocal of its *K* to obtain the new *K*.

Converting between K_P and K_c (page 705)

To relate K_P to K_c, we use the equation

$$K_P = K_c(RT)^{\Delta n_g}$$

Remember to use $R = 0.0821$ L atm mol^{-1} K^{-1}. Also, remember that Δn_g is the change in moles of gas on going from reactants to products. In Chapter 19 you will learn how to calculate equilibrium constants from thermodynamic data. These calculations give K_P for gaseous reactions.

Equilibrium laws for heterogeneous reactions (page 707)

Being able to write the equilibrium law for a heterogeneous reaction is a tool you will need in later chapters when we deal with solubility equilibria. Remember that pure solids and pure liquids do not appear in the mass action expression.

Significance of the magnitude of *K* (page 709)

Use this tool to make a rough estimate of the position of equilibrium.

- When *K* is very large, the position of equilibrium lies far to the right (toward the products).
- When *K* is very small, the position of equilibrium lies far to the left (toward the reactants).

Le Châtelier's principle

This tool lets us predict how disturbing influences shift the position of equilibrium. Factors to consider are:

- Adding or removing a reactant or product (page 711)
- Changing the volume of a gaseous equilibrium (page 712)
- Raising or lowering the temperature (page 713)
- Changing temperature changes *K* (page 714)

Catalysts or inert gases have no effect on the position of equilibrium.

Concentration table (page 716)

This is a tool you will use in almost all equilibrium calculations. Remember the following points when constructing the table:

- All entries in the table must have units of molarity (mol L^{-1}).
- Any reactant or product for which an initial concentration or amount is not given in the statement of the problem is assigned an initial concentration of zero.
- Any substance with an initial concentration of zero *must* have a positive change in concentration when the reaction proceeds to equilibrium.
- The changes in concentration are in the same ratio as the coefficients in the balanced equation. When the changes are unknown, the coefficients of *x* can be the same as the coefficients in the balanced equation.
- Only quantities in the last row (equilibrium concentrations) satisfy the equilibrium law.

Simplifications in equilibrium calculations (page 728)

When the initial reactant concentrations are larger than 1000 × K, they will change only slightly as the reaction approaches equilibrium. You can therefore expect to be able to neglect the change when it is being added to or subtracted from an initial concentration. This tool is especially useful when working problems in which K is very small and the initial conditions are not far from the final position of equilibrium. *If you use simplifying approximations, be sure to check their validity after obtaining an answer.*

PLUS = *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com.** **ILW** = An Interactive Learningware solution is available for this problem. **OH** = An Office Hour video is available for this problem. Review Problems are presented in pairs separated by blue rules. Answers to problems whose numbers appear in blue are given in Appendix B. More challenging problems are marked with an asterisk *.

Review Questions

General

15.1 Sketch a graph showing how the concentrations of the reactants and products of a typical chemical reaction vary with time during the course of the reaction. Assume no products are present at the start of the reaction. Indicate on the graph where the system has reached equilibrium.

15.2 What meanings do the terms *reactants* and *products* have when describing a chemical equilibrium?

Mass Action Expression, K_P and K_c

15.3 What is an *equilibrium law*? How is the term *reaction quotient* defined? What symbol is it given?

15.4 Under what conditions does the reaction quotient equal K_c?

15.5 Suppose for the reaction $A \rightarrow B$ the value of Q is less than K_c. Which way does the reaction have to proceed to reach equilibrium—in the forward or reverse direction?

15.6 When a chemical equation and its equilibrium constant are given, why is it not necessary to also specify the form of the mass action expression?

15.7 At 225 °C, $K_P = 6.3 \times 10^{-3}$ for the reaction

$$CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$$

Would we expect this reaction to go nearly to completion?

15.8 Here are some reactions and their equilibrium constants.

(a) $2CH_4(g) \rightleftharpoons C_2H_6(g) + H_2(g) \quad K_c = 9.5 \times 10^{-13}$

(b) $CH_3OH(g) + H_2(g) \rightleftharpoons CH_4(g) + H_2O(g)$
$K_c = 3.6 \times 10^{20}$

(c) $H_2(g) + Br_2(g) \rightleftharpoons 2HBr(g) \quad K_c = 2.0 \times 10^{9}$

Arrange these reactions in order of their increasing tendency to go to completion.

Converting between K_P and K_c

15.9 State the equation relating K_P to K_c and define all terms. Which is the only value of R that can be properly used in this equation?

15.10 Use the ideal gas law to show that the partial pressure of a gas is directly proportional to its molar concentration. What is the proportionality constant?

Heterogeneous Equilibria

15.11 What is the difference between a *heterogeneous equilibrium* and a *homogeneous equilibrium*?

15.12 Why do we omit the concentrations of pure liquids and pure solids from the mass action expression of heterogeneous reactions?

15.13 Consider the following equilibrium.

$$2NaHCO_3(s) \rightleftharpoons Na_2CO_3(s) + CO_2(g) + H_2O(g)$$

If you were converting between K_P and K_c, what value of Δn_g would you use?

Le Châtelier's Principle

15.14 State Le Châtelier's principle in your own words.

15.15 Explain, using its effect on the reaction quotient, why adding a reactant to the following equilibrium shifts the position of equilibrium to the right.

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$$

15.16 Halving the volume of a gas doubles its pressure. Using the reaction quotient corresponding to K_P, explain why halving the volume shifts the following equilibrium to the left.

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

15.17 How will the value of K_P for the following reactions be affected by an increase in temperature?

(a) $CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$
$\Delta H° = -18$ kJ

(b) $N_2O(g) + NO_2(g) \rightleftharpoons 3NO(g)$
$\Delta H° = +155.7$ kJ

(c) $2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g)$
$\Delta H° = -77.07$ kJ

15.18 Why doesn't a catalyst affect the position of equilibrium in a chemical reaction?

Review Problems

Equilibrium Laws for K_P and K_c

15.19 Write the equilibrium law for each of the following gaseous reactions in terms of molar concentrations:

(a) $2PCl_3(g) + O_2(g) \rightleftharpoons 2POCl_3(g)$

(b) $2SO_3(g) \rightleftharpoons 2SO_2(g) + O_2(g)$

(c) $N_2H_4(g) + 2O_2(g) \rightleftharpoons 2NO(g) + 2H_2O(g)$

(d) $N_2H_4(g) + 6H_2O_2(g) \rightleftharpoons 2NO_2(g) + 8H_2O(g)$

(e) $SOCl_2(g) + H_2O(g) \rightleftharpoons SO_2(g) + 2HCl(g)$

15.20 Write the equilibrium law for each of the following gaseous reactions in terms of molar concentrations.

(a) $3Cl_2(g) + NH_3(g) \rightleftharpoons NCl_3(g) + 3HCl(g)$

(b) $PCl_3(g) + PBr_3(g) \rightleftharpoons PCl_2Br(g) + PClBr_2(g)$

(c) $NO(g) + NO_2(g) + H_2O(g) \rightleftharpoons 2HNO_2(g)$

(d) $H_2O(g) + Cl_2O(g) \rightleftharpoons 2HOCl(g)$

(e) $Br_2(g) + 5F_2(g) \rightleftharpoons 2BrF_5(g)$

15.21 Write the equilibrium law for the reactions in Problem 15.19 in terms of partial pressures.

15.22 Write the equilibrium law for the reactions in Problem 15.20 in terms of partial pressures.

OH **15.23** Write the equilibrium law for each of the following reactions in aqueous solution.

(a) $Ag^+(aq) + 2NH_3(aq) \rightleftharpoons Ag(NH_3)_2{}^+(aq)$

(b) $Cd^{2+}(aq) + 4SCN^-(aq) \rightleftharpoons Cd(SCN)_4{}^{2-}(aq)$

15.24 Write the equilibrium law for each of the following reactions in aqueous solution.

(a) $HClO(aq) + H_2O \rightleftharpoons H_3O^+(aq) + ClO^-(aq)$

(b) $CO_3{}^{2-}(aq) + HSO_4{}^-(aq) \rightleftharpoons HCO_3{}^-(aq) + SO_4{}^{2-}(aq)$

Manipulating Equilibrium Equations

15.25 At 25 °C, $K_c = 1 \times 10^{-85}$ for the reaction

$$7IO_3{}^-(aq) + 9H_2O + 7H^+(aq) \rightleftharpoons I_2(aq) + 5H_5IO_6(aq)$$

What is the value of K_c for the following reaction?

$$I_2(aq) + 5H_5IO_6(aq) \rightleftharpoons 7IO_3{}^-(aq) + 9H_2O + 7H^+(aq)$$

15.26 Use the following equilibria

$$2CH_4(g) \rightleftharpoons C_2H_6(g) + H_2(g) \qquad K_c = 9.5 \times 10^{-13}$$

$$CH_4(g) + H_2O(g) \rightleftharpoons CH_3OH(g) + H_2(g) \qquad K_c = 2.8 \times 10^{-21}$$

to calculate K_c for the reaction

$$2CH_3OH(g) + H_2(g) \rightleftharpoons C_2H_6(g) + 2H_2O(g)$$

15.27 Write the equilibrium law for each of the following reactions in terms of molar concentrations:

(a) $H_2(g) + Cl_2(g) \rightleftharpoons 2HCl(g)$

(b) $\frac{1}{2}H_2(g) + \frac{1}{2}Cl_2(g) \rightleftharpoons HCl(g)$

How does K_c for reaction (a) compare with K_c for reaction (b)?

15.28 Write the equilibrium law for the reaction

$$2HCl(g) \rightleftharpoons H_2(g) + Cl_2(g)$$

How does K_c for this reaction compare with K_c for reaction (a) in Problem 15.27?

Converting between K_P and K_c

15.29 A 345 mL container holds NH_3 at a pressure of 745 torr and a temperature of 45 °C. What is the molar concentration of ammonia in the container?

15.30 In a certain container at 145 °C the concentration of water vapor is 0.0200 *M*. What is the partial pressure of H_2O in the container?

15.31 For which of the following reactions does $K_P = K_c$?

(a) $2H_2(g) + C_2H_2(g) \rightleftharpoons C_2H_6(g)$

(b) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$

(c) $2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g)$

OH **15.32** For which of the following reactions does $K_P = K_c$?

(a) $CO_2(g) + H_2(g) \rightleftharpoons CO(g) + H_2O(g)$

(b) $PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$

(c) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

OH ILW **15.33** The reaction $CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$ has $K_P = 6.3 \times 10^{-3}$ at 225 °C. What is the value of K_c at this temperature?

15.34 The reaction $HCO_2H(g) \rightleftharpoons CO(g) + H_2O(g)$ has $K_P = 1.6 \times 10^6$ at 400 °C. What is the value of K_c for this reaction at this temperature?

15.35 The reaction $N_2O(g) + NO_2(g) \rightleftharpoons 3NO(g)$ has $K_c = 4.2 \times 10^{-4}$ at 500 °C. What is the value of K_P at this temperature?

15.36 One possible way of removing NO from the exhaust of a gasoline engine is to cause it to react with CO in the presence of a suitable catalyst.

$$2NO(g) + 2CO(g) \rightleftharpoons N_2(g) + 2CO_2(g)$$

At 300 °C, this reaction has $K_c = 2.2 \times 10^{59}$. What is K_P at 300 °C?

15.37 At 773 °C the reaction $CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$ has $K_c = 0.40$. What is K_P at this temperature?

15.38 The reaction $COCl_2(g) \rightleftharpoons CO(g) + Cl_2(g)$ has $K_P = 4.6 \times 10^{-2}$ at 395 °C. What is K_c at this temperature?

Heterogeneous Equilibria

15.39 Calculate the molar concentration of water in **(a)** 18.0 mL of $H_2O(l)$, **(b)** 100.0 mL of $H_2O(l)$, and **(c)** 1.00 L of $H_2O(l)$. Assume that the density of water is 1.00 g/mL.

15.40 The density of sodium chloride is 2.164 g cm^{-3}. What is the molar concentration of NaCl in a 12.0 cm^3 sample of pure NaCl? What is the molar concentration of NaCl in a 25.0 g sample of pure NaCl?

15.41 Write the equilibrium law corresponding to K_c for each of the following heterogeneous reactions.

(a) $2C(s) + O_2(g) \rightleftharpoons 2CO(g)$

(b) $2NaHSO_3(s) \rightleftharpoons Na_2SO_3(s) + H_2O(g) + SO_2(g)$

(c) $2C(s) + 2H_2O(g) \rightleftharpoons CH_4(g) + CO_2(g)$

(d) $CaCO_3(s) + 2HF(g) \rightleftharpoons CaF_2(s) + H_2O(g) + CO_2(g)$

(e) $CuSO_4 \cdot 5H_2O(s) \rightleftharpoons CuSO_4(s) + 5H_2O(g)$

15.42 Write the equilibrium law corresponding to K_c for each of the following heterogeneous reactions.

(a) $CaCO_3(s) + SO_2(g) \rightleftharpoons CaSO_3(s) + CO_2(g)$

(b) $AgCl(s) + Br^-(aq) \rightleftharpoons AgBr(s) + Cl^-(aq)$

(c) $Cu(OH)_2(s) \rightleftharpoons Cu^{2+}(aq) + 2OH^-(aq)$

(d) $Mg(OH)_2(s) \rightleftharpoons MgO(s) + H_2O(g)$

(e) $3CuO(s) + 2NH_3(g) \rightleftharpoons 3Cu(s) + N_2(g) + 3H_2O(g)$

OH **15.43** The heterogeneous reaction $2HCl(g) + I_2(s) \rightleftharpoons 2HI(g) + Cl_2(g)$ has $K_c = 1.6 \times 10^{-34}$ at 25 °C. Suppose 0.100 mol of HCl and solid I_2 are placed in a 1.00 L container. What will be the equilibrium concentrations of HI and Cl_2 in the container?

15.44 At 25 °C, $K_c = 360$ for the reaction

$$AgCl(s) + Br^-(aq) \rightleftharpoons AgBr(s) + Cl^-(aq)$$

If solid AgCl is added to a solution containing 0.10 *M* Br^-, what will be the equilibrium concentrations of Br^- and Cl^-?

Le Châtelier's Principle

15.45 How will the position of equilibrium in the reaction

$$\text{heat} + CH_4(g) + 2H_2S(g) \rightleftharpoons CS_2(g) + 4H_2(g)$$

be affected by the following changes?

(a) Adding $CH_4(g)$

(b) Adding $H_2(g)$

(c) Removing $CS_2(g)$

(d) Decreasing in the volume of the container

(e) Increasing the temperature

OH **15.46** The reaction $CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$ has $\Delta H° = -18$ kJ. How will the amount of CH_3OH present at equilibrium be affected by the following changes?

(a) Adding $CO(g)$

(b) Removing $H_2(g)$

(c) Decreasing the volume of the container

(d) Adding a catalyst

(e) Increasing the temperature

15.47 Consider the equilibrium

$$N_2O(g) + NO_2(g) \rightleftharpoons 3NO(g) \quad \Delta H° = +155.7 \text{ kJ}$$

In which direction will this equilibrium be shifted by the following changes?

(a) Adding N_2O

(b) Removing NO_2

(c) Adding NO

(d) Increasing the temperature of the reaction mixture

(e) Adding helium gas to the reaction mixture at constant volume

(f) Decreasing the volume of the container at constant temperature

15.48 Consider the equilibrium $2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g)$ for which $\Delta H° = -77.07$ kJ. How will the amount of Cl_2 at equilibrium be affected by the following changes?

(a) Removing $NO(g)$

(b) Adding $NOCl(g)$

(c) Raising the temperature

(d) Decreasing the volume of the container

Equilibrium Calculations

15.49 At a certain temperature, $K_c = 0.18$ for the equilibrium

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$$

Suppose a reaction vessel at this temperature contained these three gases at the following concentrations: $[PCl_3] = 0.0420$ *M*, $[Cl_2] = 0.0240$ *M*, $[PCl_5] = 0.00500$ *M*.

(a) Compute the reaction quotient and use it to determine whether the system is in a state of equilibrium.

(b) If the system is not at equilibrium, in which direction will the reaction proceed to get to equilibrium?

15.50 At 460 °C, the reaction

$$SO_2(g) + NO_2(g) \rightleftharpoons NO(g) + SO_3(g)$$

has $K_c = 85.0$. A reaction flask at 460 °C contains these gases at the following concentrations: $[SO_2] = 0.00250$ *M*, $[NO_2] = 0.00350$ *M*, $[NO] = 0.0250$ *M*, $[SO_3] = 0.0400$ *M*.

(a) Is the reaction at equilibrium?

(b) If not, in which direction will the reaction proceed to arrive at equilibrium?

OH **15.51** At a certain temperature, the reaction

$$CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$$

has $K_c = 0.500$. If a reaction mixture at equilibrium contains 0.180 *M* CO and 0.220 *M* H_2, what is the concentration of $CH_3OH(g)$?

15.52 $K_P = 0.018$ for the reaction

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

at a certain temperature. Suppose it was found that in an equilibrium mixture of these gases the partial pressure of $NH_3(g)$ is 22.2 atm and the partial pressure of N_2 is 1.18 atm. What is the partial pressure of $H_2(g)$?

15.53 At 773 °C, a mixture of $CO(g)$, $H_2(g)$, and $CH_3OH(g)$ was allowed to come to equilibrium. The following equilibrium concentrations were then measured: $[CO] = 0.105\ M$, $[H_2] = 0.250\ M$, $[CH_3OH] = 0.00261\ M$. Calculate K_c for the reaction

$$CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$$

15.54 Ethylene, C_2H_4, and water react under appropriate conditions to give ethanol. The reaction is

$$C_2H_4(g) + H_2O(g) \rightleftharpoons C_2H_5OH(g)$$

An equilibrium mixture of these gases at a certain temperature had the following partial pressures: $P_{C_2H_4} = 0.575$ atm, $P_{H_2O} = 1.30$ atm, $P_{C_2H_5OH} = 6.99$ atm. What is the value of K_P?

ILW **15.55** At high temperature, 2.00 mol of HBr was placed in a 4.00 L container where it decomposed to give the equilibrium

$$2HBr(g) \rightleftharpoons H_2(g) + Br_2(g)$$

At equilibrium the concentration of Br_2 was measured to be 0.0955 *M*. What is K_c for this reaction at this temperature?

15.56 A 0.050 mol sample of formaldehyde vapor, CH_2O, was placed in a heated 500 mL vessel and some of it decomposed. The reaction is

$$CH_2O(g) \rightleftharpoons H_2(g) + CO(g)$$

At equilibrium, the $CH_2O(g)$ concentration was 0.066 mol L^{-1}. Calculate the value of K_c for this reaction.

15.57 The reaction $NO_2(g) + NO(g) \rightleftharpoons N_2O(g) + O_2(g)$ reached equilibrium at a certain high temperature. Originally, the reaction vessel contained the following initial concentrations: $[N_2O] = 0.184\ M$, $[O_2] = 0.377\ M$, $[NO_2] = 0.0560\ M$, and $[NO] = 0.294\ M$. The concentration of the NO_2, the only colored gas in the mixture, was monitored by following the intensity of the color. At equilibrium, the NO_2 concentration had become 0.118 *M*. What is the value of K_c for this reaction at this temperature?

15.58 At 25 °C, 0.0560 mol O_2 and 0.020 mol N_2O were placed in a 1.00 L container where the following equilibrium was then established.

$$2N_2O(g) + 3O_2(g) \rightleftharpoons 4NO_2(g)$$

At equilibrium, the NO_2 concentration was 0.020 *M*. What is the value of K_c for this reaction?

15.59 At 25 °C, $K_c = 0.145$ for the following reaction in the solvent CCl_4.

$$2BrCl \rightleftharpoons Br_2 + Cl_2$$

If the initial concentration of BrCl in the solution is 0.050 *M*, what will the equilibrium concentrations of Br_2 and Cl_2 be?

15.60 At 25 °C, $K_c = 0.145$ for the following reaction in the solvent CCl_4.

$$2BrCl \rightleftharpoons Br_2 + Cl_2$$

If the initial concentrations of Br_2 and Cl_2 are each 0.0250 *M*, what will their equilibrium concentrations be?

15.61 The equilibrium constant, K_c, for the reaction

$$SO_3(g) + NO(g) \rightleftharpoons NO_2(g) + SO_2(g)$$

was found to be 0.500 at a certain temperature. If 0.240 mol of SO_3 and 0.240 mol of NO are placed in a 2.00 L container and allowed to react, what will be the equilibrium concentration of each gas?

15.62 For the reaction in Problem 15.61, a reaction mixture is prepared in which 0.120 mol NO_2 and 0.120 mol of SO_2 are placed in a 1.00 L vessel. After the system reaches equilibrium, what will be the equilibrium concentrations of all four gases? How do these equilibrium values compare to those calculated in Problem 15.61? Account for your observation.

15.63 At a certain temperature the reaction

$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g)$$

has $K_c = 0.400$. Exactly 1.00 mol of each gas was placed in a 100.0 L vessel and the mixture underwent reaction. What was the equilibrium concentration of each gas?

15.64 At 25 °C, $K_c = 0.145$ for the following reaction in the solvent CCl_4.

$$2BrCl \rightleftharpoons Br_2 + Cl_2$$

If the initial concentrations of each substance in a solution are 0.0400 *M*, what will their equilibrium concentrations be?

ILW **15.65** The reaction $2HCl(g) \rightleftharpoons H_2(g) + Cl_2(g)$ has $K_c = 3.2 \times 10^{-34}$ at 25 °C. If a reaction vessel contains initially 0.0500 mol L^{-1} of HCl and then reacts to reach equilibrium, what will be the concentrations of H_2 and Cl_2?

15.66 At 200 °C, $K_c = 1.4 \times 10^{-10}$ for the reaction

$$N_2O(g) + NO_2(g) \rightleftharpoons 3NO(g)$$

If 0.200 mol of N_2O and 0.400 mol NO_2 are placed in a 4.00 L container, what would the NO concentration be if this equilibrium were established?

ILW **15.67** At 2000 °C, the decomposition of CO_2,

$$2CO_2(g) \rightleftharpoons 2CO(g) + O_2(g)$$

has $K_c = 6.4 \times 10^{-7}$. If a 1.00 L container holding 1.00×10^{-2} mol of CO_2 is heated to 2000 °C, what will be the concentration of CO at equilibrium?

15.68 At 500 °C, the decomposition of water into hydrogen and oxygen,

$$2H_2O(g) \rightleftharpoons 2H_2(g) + O_2(g)$$

has $K_c = 6.0 \times 10^{-28}$. How many moles of H_2 and O_2 are present at equilibrium in a 5.00 L reaction vessel at this temperature if the container originally held 0.015 mol H_2O?

15.69 At a certain temperature, $K_c = 0.18$ for the equilibrium

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$$

If 0.026 mol of PCl_5 is placed in a 2.00 L vessel at this temperature, what will the concentration of PCl_3 be at equilibrium?

15.70 At 460 °C, the reaction

$$SO_2(g) + NO_2(g) \rightleftharpoons NO(g) + SO_3(g)$$

has $K_c = 85.0$. Suppose 0.100 mol of SO_2, 0.0600 mol of NO_2, 0.0800 mol of NO, and 0.120 mol of SO_3 are placed in a 10.0 L container at this temperature. What will the concentrations of all the gases be when the system reaches equilibrium?

15.71 At a certain temperature, $K_c = 0.500$ for the reaction

$$SO_3(g) + NO(g) \rightleftharpoons NO_2(g) + SO_2(g)$$

If 0.100 mol SO_3 and 0.200 mol NO are placed in a 2.00 L container and allowed to come to equilibrium, what will the NO_2 and SO_2 concentrations be?

15.72 At 25 °C, $K_c = 0.145$ for the following reaction in the solvent CCl_4.

$$2BrCl \rightleftharpoons Br_2 + Cl_2$$

A solution was prepared with the following initial concentrations: [BrCl] = 0.0400 *M*, [Br_2] = 0.0300 *M*, and [Cl_2] = 0.0200 *M*. What will their equilibrium concentrations be?

*__15.73__ At a certain temperature, $K_c = 4.3 \times 10^5$ for the reaction

$$HCO_2H(g) \rightleftharpoons CO(g) + H_2O(g)$$

If 0.200 mol of HCO_2H is placed in a 1.00 L vessel, what will be the concentrations of CO and H_2O when the system reaches equilibrium? (*Hint:* Where does the position of equilibrium lie when *K* is very large?)

*__15.74__ The reaction $H_2(g) + Br_2(g) \rightleftharpoons 2HBr(g)$ has $K_c = 2.0 \times 10^9$ at 25 °C. If 0.100 mol of H_2 and 0.200 mol of Br_2 are placed in a 10.0 L container, what will all the equilibrium concentrations be at 25 °C? (*Hint:* Where does the position of equilibrium lie when *K* is very large?)

Additional Exercises

OH **15.75** The reaction $N_2O_4(g) \rightleftharpoons 2NO_2(g)$ has $K_P = 0.140$ at 25 °C. In a reaction vessel containing these gases in equilibrium at this temperature, the partial pressure of N_2O_4 was 0.250 atm.

(a) What was the partial pressure of the NO_2 in the reaction mixture?

(b) What was the total pressure of the mixture of gases?

15.76 At 25 °C, the following concentrations were found for the gases in an equilibrium mixture for the reaction

$$N_2O(g) + NO_2(g) \rightleftharpoons 3NO(g)$$

[NO_2] = 0.24 *M*, [NO] = 4.8×10^{-8} *M*, and [N_2O] = 0.023 *M*. What is the value of K_P for this reaction?

15.77 The following reaction in aqueous solution has $K_c = 1 \times 10^{-85}$ at a temperature of 25 °C.

$$7IO_3^-(aq) + 9H_2O + 7H^+(aq) \rightleftharpoons I_2(aq) + 5H_5IO_6(aq)$$

What is the equilibrium law for this reaction?

*__15.78__ At a certain temperature, $K_c = 0.914$ for the reaction

$$NO_2(g) + NO(g) \rightleftharpoons N_2O(g) + O_2(g)$$

A mixture was prepared containing 0.200 mol NO_2, 0.300 mol NO, 0.150 mol N_2O, and 0.250 mol O_2 in a 4.00 L container. What will be the equilibrium concentrations of each gas?

*__15.79__ At 27 °C, $K_P = 1.5 \times 10^{18}$ for the reaction

$$3NO(g) \rightleftharpoons N_2O(g) + NO_2(g)$$

If 0.030 mol of NO were placed in a 1.00 L vessel and this equilibrium were established, what would be the equilibrium concentrations of NO, N_2O, and NO_2?

15.80 Consider the equilibrium

$$2NaHSO_3(s) \rightleftharpoons Na_2SO_3(s) + H_2O(g) + SO_2(g)$$

How will the position of equilibrium be affected by the following changes?

(a) Adding $NaHSO_3$ to the reaction vessel

(b) Removing Na_2SO_3 from the reaction vessel

(c) Adding H_2O to the reaction vessel

(d) Increasing the volume of the reaction vessel

15.81 At a certain temperature, $K_c = 0.914$ for the reaction

$$NO_2(g) + NO(g) \rightleftharpoons N_2O(g) + O_2(g)$$

A mixture was prepared containing 0.200 mol of each gas in a 5.00 L container. What will be the equilibrium concentration of each gas? How will the concentrations then change if 0.050 mol of NO_2 is added to the equilibrium mixture?

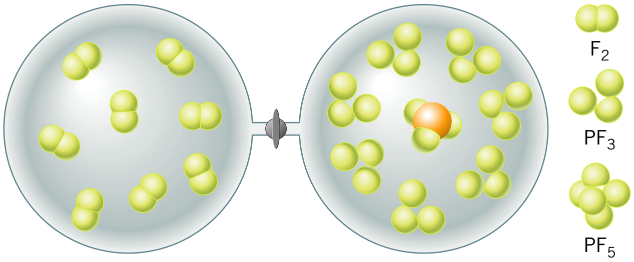
*15.82 At a certain temperature, $K_c = 0.914$ for the reaction

$$NO_2(g) + NO(g) \rightleftharpoons N_2O(g) + O_2(g)$$

Equal amounts of NO and NO_2 are to be placed in a 5.00 L container until the N_2O concentration at equilibrium is 0.0500 *M*. How many moles of NO and NO_2 must be placed in the container?

15.83 Two 1.00 L bulbs are filled with 0.500 atm of $F_2(g)$ and $PF_3(g)$, respectively, as illustrated in the figure below. At a particular temperature, $K_P = 4.0$ for the reaction of these gases to form $PF_5(g)$:

$$F_2(g) + PF_3(g) \rightleftharpoons PF_5(g)$$



(a) The stopcock between the bulbs is opened and the pressure falls. Make a sketch of this apparatus showing the gas composition once the pressure is stable.

(b) List any chemical reactions that continue to occur once the pressure is stable.

(c) Suppose all the gas in the left bulb is forced into the bulb on the right and then the stopcock is closed. Make a second sketch to show the composition of the gas mixture after equilibrium is reached. Comment on how the composition of the one-bulb system differs from that for the two-bulb system.

OH 15.84 For the equilibrium

$$3NO_2(g) \rightleftharpoons N_2O_5(g) + NO(g)$$

$K_c = 1.0 \times 10^{-11}$. If a 4.00 L container initially holds 0.20 mol of NO_2, how many moles of N_2O_5 will be present when this system reaches equilibrium?

15.85 To study the following reaction at 20 °C,

$$NO(g) + NO_2(g) + H_2O(g) \rightleftharpoons 2HNO_2(g)$$

a mixture of $NO(g)$, $NO_2(g)$, and $H_2O(g)$ was prepared in a 10.0 L glass bulb. For NO, NO_2, and HNO_2, the initial concentrations were as follows: $[NO] = [NO_2] = 2.59 \times 10^{-3}$ *M* and $[HNO_2] = 0.0$ *M*. The initial partial pressure of $H_2O(g)$ was 17.5 torr. When equilibrium was reached, the HNO_2 concentration was 4.0×10^{-4} *M*. Calculate the equilibrium constant, K_c, for this reaction.

15.86 At 100.0 °C, $K_c = 0.135$ for the reaction

$$3H_2(g) + N_2(g) \rightleftharpoons 2NH_3(g)$$

In a reaction mixture at equilibrium at this temperature, $[NH_3] = 0.030$ *M* and $[N_2] = 0.50$ *M*. What are the partial pressures of all of the gases in the mixture? Use them to calculate K_P and compare the result with K_P calculated using Equation 15.9.

Multi-Concept Problems

*15.87 For the reaction below, $K_P = 1.6 \times 10^6$ at 400.0 °C.

$$HCHO_2(g) \rightleftharpoons CO(g) + H_2O(g)$$

A mixture of $CO(g)$ and $H_2O(l)$ was prepared in a 2.00 L reaction vessel at 25 °C in which the pressure of CO was 0.177 atm. The mixture also contained 0.391 g of H_2O. The vessel was sealed and heated to 400 °C. When equilibrium was reached, what was the partial pressure of the $HCHO_2$ at 400 °C?

*15.88 At 2000 °C, the decomposition of CO_2,

$$2CO_2(g) \rightleftharpoons 2CO(g) + O_2(g)$$

has $K_c = 6.4 \times 10^{-7}$. If a 1.00 L container holding 1.00×10^{-2} mol of CO_2 is heated to 2000 °C, what will be the partial pressure of CO (in atmospheres) at equilibrium? How many molecules of O_2 are present at equilibrium? How, if at all, does the density of the mixture change as it goes from its initial condition to its equilibrium state? How much heat, in joules, is absorbed or evolved in the approach to equilibrium?

*15.89 At 460 °C, the reaction

$$SO_2(g) + NO_2(g) \rightleftharpoons NO(g) + SO_3(g)$$

has $K_c = 85.0$. If 0.0255 mol of SO_2, 0.0600 mol of NO_2, 0.0800 mol of NO, and 0.0446 mol of SO_3 are placed in a 10.0 L container at this temperature, how many grams of each gas will be present when the mixture reaches equilibrium? What will the total pressure of the system be at equilibrium?

*15.90 At 200.0 °C, $K_c = 1.4 \times 10^{-10}$ for the reaction

$$N_2O(g) + NO_2(g) \rightleftharpoons 3NO(g)$$

If 300 mL of NO measured at 800 torr and 25 °C is placed in a 4.00 L container, what will be the N_2O and NO molar concentrations at equilibrium? What will be the total pressure of the mixture (in torr) at equilibrium?

***15.91** At 400 °C, $K_c = 2.9 \times 10^4$ for the reaction

$$HCHO_2(g) \rightleftharpoons CO(g) + H_2O(g)$$

A mixture was prepared with the following initial concentrations: $[CO] = 0.20\ M$, $[H_2O] = 0.30\ M$. No formic acid, $HCHO_2$, was initially present. What was the equilibrium concentration of $HCHO_2$? What is the density of the equilibrium mixture?

***15.92** The reaction $N_2O_4(g) \rightleftharpoons 2NO_2(g)$ has $K_P = 0.140$ at 25.0 °C. Into a 4.50 L reaction vessel at this temperature was placed 0.0245 mol N_2O_4 and 0.0116 mol N_2O. What will be the density of the gas mixture (in units of gram per liter) **(a)** before the reaction starts, and **(b)** at equilibrium?

Exercises in Critical Thinking

15.93 In an equilibrium law, coefficients in the balanced equation appear as exponents on concentrations. Why, in general, does this not also apply for rate laws?

15.94 Why are equilibrium concentrations useful to know?

15.95 Suppose we set up a system in which water is poured into a vessel having a hole in the bottom. If the rate of water inflow is adjusted so that it matches the rate at which water drains through the hole, the amount of water in the vessel remains constant over time. Is this an equilibrium system? Explain.

15.96 Do equilibrium laws apply to other systems outside of chemistry? Give examples.

15.97 What might prevent a system from reaching dynamic equilibrium? Illustrate your answer with examples.

15.98 After many centuries the earth's atmosphere still has not come to equilibrium with the oceans and land. What factors are responsible for this?

15.99 If a mixture consisting of many small crystals in contact with a saturated solution is studied for a period of time, the smallest of the crystals are observed to dissolve while the larger ones grow even larger. Explain this phenomenon in terms of a dynamic equilibrium.

16 Acids and Bases, A Molecular Look

Chapter Outline

16.1 | Brønsted–Lowry Definition of Acids and Bases

16.2 | Strengths of Brønsted–Lowry Acids and Bases

16.3 | Periodic Trends in the Strengths of Acids

16.4 | Lewis Definition of Acids and Bases

16.5 | Acid–Base Properties of Elements and Their Oxides

16.6 | Advanced Ceramics and Acid–Base Chemistry

The chief method for making steel is called the basic oxygen process, in which pure oxygen is blown through a molten mixture of scrap steel and iron formed from iron ore in a blast furnace. The oxygen burns off excess carbon and oxidizes impurities such as silicon to oxides, like SiO_2. Calcium and magnesium oxide is added to combine with the SiO_2 to form molten slag, a process that involves an acid–base reaction. However, to describe this reaction adequately requires that we redefine acids and bases in a broader way that does not involve water or hydrogen ions. Such a definition is one of the topics discussed in this chapter. © AP/Wide World Photos.

This Chapter in Context

In Chapter 5 we introduced you to compounds that we call acids and bases. Many common substances, from household products such as vinegar and ammonia, to biologically important compounds such as amino acids, are conveniently classified as either an acid or a base. The significant property that makes such classifications useful is that *acids react with bases*. In fact, this is such a useful relationship that the acid–base concept has been expanded far beyond the limited Arrhenius definition we discussed in Chapter 5. We now return to acid–base chemistry to learn about these broader and often more useful views.

At the same time, we will study how trends in the strengths of acids and bases correlate with the periodic table. We will use the principles developed in previous chapters to explain why one acid should be stronger than another. The ability to judge relative acid strengths is an important skill to bring to the study of organic chemistry. (In the next chapter we will assign a numerical value that helps us more precisely compare strengths of acids and bases.) And finally, we will examine a modern application of acid–base chemistry to the production of useful high-tech materials.

16.1 | Brønsted–Lowry Definition of Acids and Bases

In Chapter 5, an acid was described as a substance that produces H_3O^+ in water, whereas a base gives OH^-. An acid–base neutralization, according to Arrhenius, is a reaction in which an acid and a base combine to produce water and a salt. However, many reactions resemble neutralizations without involving H_3O^+, OH^-, or even H_2O. For example, when open bottles of concentrated hydrochloric acid and concentrated aqueous ammonia are placed side by side, a white cloud forms when the vapors from the two bottles mix (see Figure 16.1). The cloud consists of tiny crystals of ammonium chloride, which form when ammonia and hydrogen chloride gases, escaping from the open bottles, mix in air and react.

$$NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$$

What's interesting is that this is the same net reaction that occurs when an aqueous solution of ammonia (a base) is neutralized by an aqueous solution of hydrogen chloride (an acid). Yet, the gaseous reaction doesn't fit the description of an acid–base neutralization according to the Arrhenius definition because there's no water involved.

If we look at both the aqueous and gaseous reactions, they do have something in common. Both involve the transfer of a *proton* (a hydrogen ion, H^+) from one particle to another.[1] In water, where HCl is completely ionized, the transfer is from H_3O^+ to NH_3, as we discussed on page 179. The ionic equation is shown below.

$$NH_3(aq) + H_3O^+(aq) + Cl^-(aq) \longrightarrow \underbrace{NH_4^+(aq) + Cl^-(aq)}_{\text{The ions of } NH_4Cl} + H_2O$$

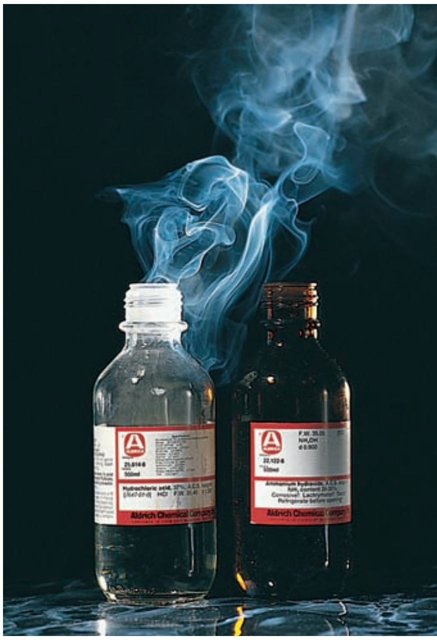


Figure 16.1 | **The reaction of gaseous HCl with gaseous NH_3.** As each gas escapes from its concentrated aqueous solution and mingles with the other, a cloud of microcrystals of NH_4Cl forms above the bottles. *(Andy Washnik)*

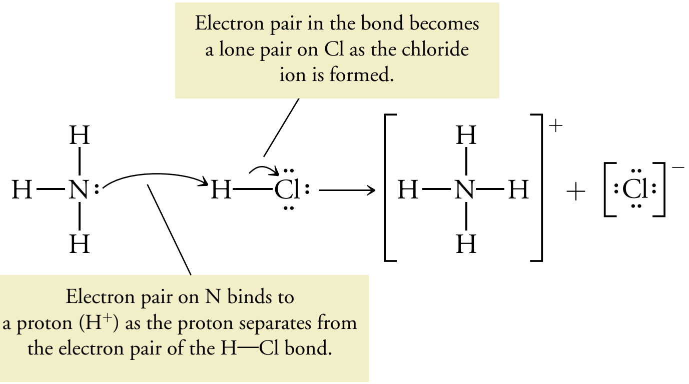
---

[1] When the single electron is removed from a hydrogen atom, what remains is just the nucleus of the atom, which is a proton. Therefore, a hydrogen ion, H^+, consists of a proton, and the terms *proton* and *hydrogen ion* are often used interchangeably.

In the gas phase, the proton is transferred directly from the HCl molecule to the NH_3 molecule.

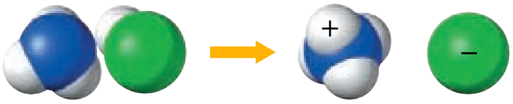
■ We are using "curved" arrows to show how electrons shift and rearrange during the formation of the ions. The electron pair on the nitrogen atom of the NH_3 molecule binds to H^+ as it is removed from the electron pair in the H—Cl bond. The electron pair in the H—Cl bond shifts entirely to the Cl as the Cl^- ion is formed.



Electron pair in the bond becomes a lone pair on Cl as the chloride ion is formed.

Electron pair on N binds to a proton (H^+) as the proton separates from the electron pair of the H—Cl bond.

■ Although the positive charge is shown on just one of the hydrogens in NH_4^+, it is actually spread equally over all four hydrogens.



As ammonium ions and chloride ions form, they attract each other, gather, and settle as crystals of ammonium chloride.

Proton Transfer Reactions

Johannes Brønsted (1879–1947), a Danish chemist, and Thomas Lowry (1874–1936), a British scientist, realized that the important event in most acid–base reactions is simply the transfer of a proton from one particle to another. Therefore, they redefined *acids* as substances that donate protons and *bases* as substances that accept protons. The heart of the *Brønsted–Lowry concept of acids and bases* is that *acid–base reactions are proton transfer reactions.* The definitions are therefore very simple.

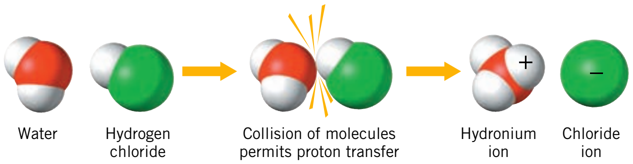
Brønsted–Lowry definitions

Brønsted–Lowry Definitions of Acids and Bases[2]
An **acid** is a proton donor.
A **base** is a proton acceptor.

Accordingly, hydrogen chloride is an acid because when it reacts with ammonia, HCl molecules donate protons to NH_3 molecules. Similarly, ammonia is a base because NH_3 molecules accept protons.

Even when water is the solvent, chemists use the Brønsted–Lowry definitions more often than those of Arrhenius. Thus, the reaction between hydrogen chloride and water to form hydronium ion (H_3O^+) and chloride ion (Cl^-), which is another proton transfer reaction, is clearly a Brønsted–Lowry acid–base reaction. Molecules of HCl are the acid in this reaction, and water molecules are the base. HCl molecules collide with water molecules and protons transfer during the collisions.

■ In H_3O^+, the positive charge is actually spread equally over all three hydrogens.



---

[2] Although Brønsted and Lowry are both credited with defining acids and bases in terms of proton transfer, Brønsted carried the concepts further. For the sake of brevity, we will often use the terms *Brønsted acid* and *Brønsted base* when referring to the substances involved in proton transfer reactions.

Conjugate Acids and Bases

Under the Brønsted–Lowry view, it is useful to consider any acid–base reaction as a chemical equilibrium, having both a forward and a reverse reaction. We first encountered a chemical equilibrium in a solution of a weak acid on page 170. Let's examine it again in the light of the Brønsted–Lowry definitions, using formic acid, $HCHO_2$, as an example. Because formic acid is a weak acid, we represent its ionization as a chemical equilibrium in which water is not just a solvent but also a chemical reactant, a proton acceptor.[3]

$$HCHO_2(aq) + H_2O \rightleftharpoons H_3O^+(aq) + CHO_2^-(aq)$$

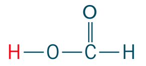
In the forward reaction, a formic acid molecule donates a proton to the water molecule and changes to a formate ion, CHO_2^- (Figure 16.2*a*). Thus $HCHO_2$ behaves as a Brønsted acid, a proton donor. Because water accepts this proton from $HCHO_2$, water behaves as a Brønsted base, a proton acceptor.

Now let's look at the reverse reaction (Figure 16.2*b*). In it, H_3O^+ behaves as a Brønsted acid because it donates a proton to the CHO_2^- ion. The CHO_2^- ion behaves as a Brønsted base by accepting the proton.

The equilibrium involving $HCHO_2$, H_2O, H_3O^+, and CHO_2^- is typical of proton transfer equilibria in general, in that we can identify *two* acids (e.g., $HCHO_2$ and H_3O^+) and *two* bases (e.g., H_2O and CHO_2^-). Notice that in the aqueous formic acid equilibrium, the acid on the right of the arrows (H_3O^+) is formed from the base on the left (H_2O), and the base on the right (CHO_2^-) is formed from the acid on the left ($HCHO_2$).

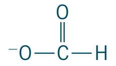
Two substances that differ from each other only by one proton are referred to as a **conjugate acid–base pair**. Thus, H_3O^+ and H_2O are such a pair; they are alike except that H_3O^+ has one more proton than H_2O. One member of the pair is called the **conjugate acid** because it is the proton donor of the two. The other member is the **conjugate base** because it is the pair's proton acceptor. We say that *H_3O^+ is the conjugate acid of H_2O*, and *H_2O is the conjugate base of H_3O^+*. Notice that *the acid member of the pair has one more H^+ than the base member.*

The pair $HCHO_2$ and CHO_2^- is the other conjugate acid–base pair in the aqueous formic acid equilibrium. $HCHO_2$ has one more H^+ than CHO_2^-, so the conjugate acid of CHO_2^- is $HCHO_2$; the conjugate base of $HCHO_2$ is CHO_2^-. One way to highlight



formic acid ($HCHO_2$)

Only the H in red is available in an acid–base reaction.



formate ion (CHO_2^-)

Conjugate acid–base pairs

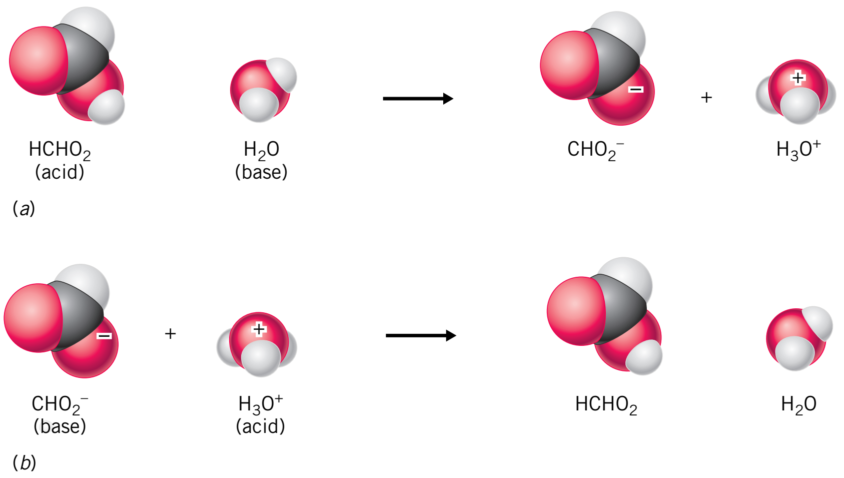


Figure 16.2 | **Brønsted–Lowry acids and bases in aqueous formic acid.** (*a*) Formic acid transfers a proton to a water molecule. $HCHO_2$ is the acid and H_2O is the base. (*b*) When hydronium ion transfers a proton to the CHO_2^- ion, H_3O^+ is the acid and CHO_2^- is the base.

---

[3] Just as we have represented acetic acid as $HC_2H_3O_2$, placing the ionizable or acidic hydrogen first (as we do in HCl or HNO_3), so we give the formula of formic acid as $HCHO_2$ and the formula of the formate ion as CHO_2^-. As the chemical structure shows, however, the acidic hydrogen in formic acid is bonded to O, not C. Many chemists prefer to write formic acid as HCO_2H.

the two members of a conjugate acid–base pair in an equilibrium equation is to connect them by a line.

Conjugate acid–base equilibria

■ Notice how the conjugate acid always has one more H^+ than the conjugate base.

$$\overbrace{\underset{\text{acid}}{\mathrm{HCHO_2}} + \underbrace{\underset{\text{base}}{\mathrm{H_2O}} \rightleftharpoons \underset{\text{acid}}{\mathrm{H_3O^+}}}_{\text{conjugate pair}} + \underset{\text{base}}{\mathrm{CHO_2^-}}}^{\text{conjugate pair}} \tag{16.1}$$

In any Brønsted–Lowry acid–base equilibrium, there are invariably *two* conjugate acid–base pairs. It is important that you learn how to pick them out of an equation by inspection and to write them from formulas.

Example 16.1
Determining the Formulas of Conjugate Acids and Bases

What is the conjugate base of nitric acid, HNO_3, and what is the conjugate acid of the hydrogen sulfate ion, HSO_4^-?

■ **Analysis:** Any reference to a conjugate acid or a conjugate base signals that the problem involves the Brønsted–Lowry acid–base concept. The key to answering the questions posed here is knowing the definitions, so be sure you've learned them.

■ **Assembling the Tools:** The tool required states that members of any conjugate acid–base pair differ by one (and *only* one) H^+, with the member having the greater number of hydrogens being the acid.

■ **Solution:** We are asked to find the conjugate base of HNO_3, which means HNO_3 must be the acid member of the pair. To find the formula of the base, we remove one H^+ from the acid. Removing one H^+ (both the atom and the charge) from HNO_3 leaves NO_3^-, so the nitrate ion is the conjugate base of HNO_3.

We are also asked to find the conjugate acid of HSO_4^-, so HSO_4^- must be the base member of an acid–base pair. To find the formula of the acid, we add one H^+ to the base, which is equivalent to adding one hydrogen to the formula of the base and increasing its positive charge (or decreasing its negative charge) by one unit. Adding an H^+ to HSO_4^- gives its conjugate acid, H_2SO_4.

■ **Are the Answers Reasonable?** As a check, we can quickly compare the two formulas in each pair.

$$\begin{array}{ll} \mathrm{HNO_3} & \mathrm{NO_3^-} \\ \mathrm{H_2SO_4} & \mathrm{HSO_4^-} \end{array}$$

In each case, the formula on the right has one less H^+ than the one on the left, so it is the conjugate base. We've answered the question correctly.

Practice Exercises

16.1 | Which of the following are conjugate acid–base pairs? Describe why the others are not true conjugate acid–base pairs. (a) H_3PO_4 and $H_2PO_4^-$, (b) HI and H^+, (c) NH_2^- and NH_3, (d) HNO_2 and NH_4^+, (e) CO_3^{2-} and CN^-, (f) HPO_4^{2-} and $H_2PO_4^-$. (*Hint:* Recall that conjugate acid–base pairs must differ by one H^+.)

16.2 | Write the formula of the conjugate base for each of the following Brønsted–Lowry acids: (a) H_2O, (b) HI, (c) HNO_2, (d) H_3PO_4, (e) $H_2PO_4^-$, (f) HPO_4^{2-}, (g) H_2S, (h) NH_4^+.

16.3 | Write the formula of the conjugate acid for each of the following Brønsted–Lowry bases: (a) HO_2^-, (b) SO_4^{2-}, (c) CO_3^{2-}, (d) CN^-, (e) NH_2^-, (f) NH_3, (g) $H_2PO_4^-$, (h) HPO_4^{2-}.

Example 16.2

Identifying Conjugate Acid–Base Pairs in a Brønsted–Lowry Acid–Base Reaction

The anion of sodium hydrogen sulfate, HSO_4^-, reacts as follows with the phosphate ion, PO_4^{3-}.

$$HSO_4^-(aq) + PO_4^{3-}(aq) \longrightarrow SO_4^{2-}(aq) + HPO_4^{2-}(aq)$$

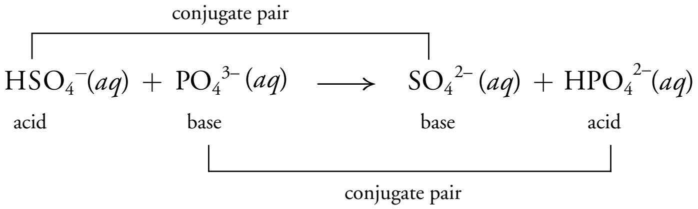
Identify the two conjugate acid–base pairs.

■ Sodium hydrogen sulfate (also called sodium bisulfate) is used to manufacture certain kinds of cement and to clean oxide coatings from metals.

■ **Analysis:** There are two things to look for in identifying the conjugate acid–base pairs in an equation. One is that the members of a conjugate pair are alike except for the number of hydrogens and the charge. The second is that the members of each pair must be on opposite sides of the arrow, as in Equation 16.1, and we cannot have both acids (or both bases) on the same side of the equation. In each pair, of course, the acid is the one with the greater number of hydrogens.

■ **Assembling the Tools:** We will use Equation 16.1 as a template to establish the relationships among the acid–base members of the two pairs.

■ **Solution:** Two of the formulas in the equation contain "PO_4," so they must belong to the same conjugate pair. The one with the greater number of hydrogens, HPO_4^{2-}, must be the Brønsted–Lowry acid, and the other, PO_4^{3-}, must be the Brønsted–Lowry base. Therefore, one conjugate acid–base pair is HPO_4^{2-} and PO_4^{3-}. The other two ions, HSO_4^- and SO_4^{2-}, belong to the second conjugate acid–base pair; HSO_4^- is the conjugate acid and SO_4^{2-} is the conjugate base.



$$\underset{\text{acid}}{HSO_4^-(aq)} + \underset{\text{base}}{PO_4^{3-}(aq)} \longrightarrow \underset{\text{base}}{SO_4^{2-}(aq)} + \underset{\text{acid}}{HPO_4^{2-}(aq)}$$

■ **Is the Answer Reasonable?** A check assures us that we have fulfilled the requirements that each conjugate pair has one member on one side of the arrow and the other member on the opposite side of the arrow and that the members of each pair differ from each other by one (and *only* one) H^+.

Practice Exercises

16.4 | Sodium cyanide solution, when poured into excess hydrochloric acid, releases hydrogen cyanide as a gas. The reaction is

$$NaCN(aq) + HCl(aq) \longrightarrow HCN(g) + NaCl(aq)$$

Identify the conjugate acid–base pairs in this reaction. (*Hint:* It may be more obvious if the spectator ions are removed.)

16.5 | One kind of baking powder contains sodium bicarbonate and calcium dihydrogen phosphate. When water is added, a reaction occurs by the following net ionic equation.

$$HCO_3^-(aq) + H_2PO_4^-(aq) \longrightarrow H_2CO_3(aq) + HPO_4^{2-}(aq)$$

Identify the two Brønsted acids and the two Brønsted bases in this reaction. (The H_2CO_3 decomposes to release CO_2, which causes the cake batter to rise.)

16.6 | When some of the strong cleaning agent "trisodium phosphate" is mixed with household vinegar, which contains acetic acid, the following equilibrium is one of the many that are established. (The position of equilibrium lies to the right.) Identify the pairs of conjugate acids and bases.

$$PO_4^{3-}(aq) + HC_2H_3O_2(aq) \rightleftharpoons HPO_4^{2-}(aq) + C_2H_3O_2^-(aq)$$

Amphoteric Substances

Some molecules or ions are able to function either as an acid or as a base, depending on the kind of substance mixed with them. For example, in its reaction with hydrogen chloride, water behaves as a *base* because it *accepts* a proton from the HCl molecule.

$$\underset{\text{base}}{H_2O} + \underset{\text{acid}}{HCl(g)} \longrightarrow H_3O^+(aq) + Cl^-(aq)$$

On the other hand, water behaves as an *acid* when it reacts with the weak base ammonia.

$$\underset{\text{acid}}{H_2O} + \underset{\text{base}}{NH_3(aq)} \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

Here, H_2O *donates* a proton to NH_3 in the forward reaction.

■ From the Greek *amphoteros,* "partly one and partly the other."

A substance that can be either an acid or a base depending on the other substance present is said to be **amphoteric.** Another term is **amphiprotic**, which stresses that the *proton* donating or accepting ability is of central concern.

Amphoteric or amphiprotic substances may be either molecules or ions. For example, anions of acid salts, such as the bicarbonate ion of baking soda, are amphoteric. The HCO_3^- ion can either donate a proton to a base or accept a proton from an acid. Thus, toward the hydroxide ion, the bicarbonate ion is an acid; it donates its proton to OH^-.

$$\underset{\text{acid}}{HCO_3^-(aq)} + \underset{\text{base}}{OH^-(aq)} \longrightarrow CO_3^{2-}(aq) + H_2O$$

Toward hydronium ion, however, HCO_3^- is a base; it accepts a proton from H_3O^+.

$$\underset{\text{base}}{HCO_3^-(aq)} + \underset{\text{acid}}{H_3O^+(aq)} \longrightarrow H_2CO_3(aq) + H_2O$$

[Recall that H_2CO_3 (carbonic acid) almost entirely decomposes to $CO_2(g)$ and water as it forms.]

Practice Exercises

16.7 | Which of the following are amphoteric and which are not? Provide reasons for your decisions. (a) $H_2PO_4^-$, (b) HPO_4^{2-}, (c) H_2S, (d) H_3PO_4, (e) NH_4^+, (f) H_2O, (g) HI, (h) HNO_2. (*Hint:* Amphoteric substances must be able to provide an H^+ and also react with an H^+.)

16.8 | The anion of sodium monohydrogen phosphate, Na_2HPO_4, is amphoteric. Using H_3O^+ and OH^-, write net ionic equations that illustrate this property.

16.2 | Strengths of Brønsted–Lowry Acids and Bases

Brønsted–Lowry acids and bases have differing abilities to lose or gain protons. In this section we examine how these abilities can be compared and how we can anticipate differences according to the locations of key elements in the periodic table.

Comparing Acids and Bases to a Relative Standard

When we speak of the strength of a Brønsted–Lowry acid, we are referring to its ability to donate a proton to a base. We measure this by determining the extent to which the reaction of the acid with the base proceeds toward completion—the more complete the reaction, the stronger the acid. To compare the strengths of a series of acids, we have to select some reference base, and because we are interested most in reactions in aqueous media, that base is usually water (although other reference bases could also be chosen).

In Chapter 5 we discussed strong and weak acids from the Arrhenius point of view, and much of what we said there applies when the same acids are studied using the Brønsted–Lowry concept. Thus, acids such as HCl and HNO_3 react completely with water to give H_3O^+ because they are strong proton donors. Hence, we classify them as *strong Brønsted–Lowry acids*. On the other hand, acids such as HNO_2 (nitrous acid) and $HC_2H_3O_2$ (acetic acid) are much weaker proton donors. Their reactions with water are far from complete, and we classify them as *weak acids*.

In a similar manner, the relative strengths of Brønsted *bases* are assigned according to their abilities to accept and bind protons. Once again, to compare strengths, we have to choose a standard acid. Because water is amphiprotic, it can serve as the standard acid as well. Substances that are powerful proton acceptors, such as the oxide ion, react completely and are considered to be *strong Brønsted–Lowry bases*.

$$O^{2-} + H_2O \xrightarrow{100\%} 2OH^-$$

Weaker proton acceptors, such as ammonia, undergo incomplete reactions with water; we classify them as *weak bases*.

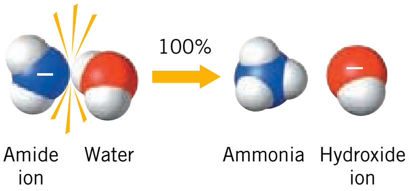
Hydronium Ion and Hydroxide Ion in Water

Both HCl and HNO_3 are very powerful proton donors. When placed in water they react completely, losing their protons to water molecules to yield H_3O^+ ions. Representing them by the general formula HA, we have

$$\underset{\text{acid}}{HA} + \underset{\text{base}}{H_2O} \xrightarrow{100\%} \underset{\text{acid}}{H_3O^+} + \underset{\text{base}}{A^-}$$

Because both reactions go to completion, we really can't tell which of the two, HCl or HNO_3, is actually the better proton donor (stronger acid). This would require a reference base less willing than water to accept protons. In water, both HCl and HNO_3 converted quantitatively to another acid, H_3O^+. The conclusion, therefore, is that *H_3O^+ is the strongest acid we will ever find in an aqueous solution*, because stronger acids react completely with water to give H_3O^+.

A similar conclusion is reached regarding hydroxide ion. We noted that the strong Brønsted base O^{2-} reacts completely with water to give OH^-. Another very powerful proton acceptor is the amide ion, NH_2^-, which also reacts completely with water.



Of course, we can also express this reaction in the form of a regular chemical equation,

$$\underset{\text{base}}{NH_2^-} + \underset{\text{acid}}{H_2O} \xrightarrow{100\%} \underset{\text{acid}}{NH_3} + \underset{\text{base}}{OH^-}$$

Using water as the reference acid, we can't tell which is the better proton acceptor, O^{2-} or NH_2^-, because both react completely, being replaced by another base, OH^-. Therefore, we can say that *OH^- is the strongest base we will ever find in an aqueous solution*, because stronger bases react completely with water to give OH^-.

Comparing Acid–Base Strengths of Conjugate Pairs

The chemical equation for the ionization of an acid in water actually shows two Brønsted–Lowry acids. One is the acid itself and the other is hydronium ion. In almost every case, one of the acids is stronger than the other, and the position of equilibrium tells us which of the two acids is stronger. Let's see how this works using the acetic acid equilibrium, in which the position of equilibrium lies to the left.

$$\underset{\text{acid}}{HC_2H_3O_2(aq)} + \underset{\text{base}}{H_2O} \rightleftharpoons \underset{\text{acid}}{H_3O^+(aq)} + \underset{\text{base}}{C_2H_3O_2^-(aq)}$$

The two Brønsted–Lowry acids in this equilibrium are $HC_2H_3O_2$ and H_3O^+, and it's helpful to think of them as competing with each other in donating protons to acceptors. The fact that nearly all potential protons stay on the $HC_2H_3O_2$ molecules, and only a relative few spend their time on the H_3O^+ ions, means that the *hydronium ion is a better proton donor than the acetic acid molecule.* Thus, the hydronium ion is a stronger Brønsted–Lowry acid than acetic acid, and we inferred this relative acidity from the position of equilibrium.

The acetic acid equilibrium also has two bases, $C_2H_3O_2^-$ and H_2O. Both compete for any available protons. But at equilibrium, most of the protons originally carried by acetic acid are still found on $HC_2H_3O_2$ molecules; relatively few are joined to H_2O in the form of H_3O^+ ions. This means that *acetate ions must be more effective than water molecules at obtaining and holding protons from proton donors.* This is the same as saying that the acetate ion is a stronger base than the water molecule, a fact we are able to infer, once again, from the position of the acetic acid equilibrium.

The preceding analysis of the acetic acid equilibrium brings out an important point. Notice that both the weaker of the two acids and the weaker of the two bases are found on the same side of the equation, which is the side favored by the position of equilibrium.

TOOLS

Acid–base strength and the position of equilibrium

The position of an acid–base equilibrium favors the weaker acid and base.

$$\underset{\text{weaker acid}}{HC_2H_3O_2(aq)} + \underset{\text{weaker base}}{H_2O} \rightleftharpoons \underset{\text{stronger acid}}{H_3O^+(aq)} + \underset{\text{stronger base}}{C_2H_3O_2^-(aq)}$$

← *Position of equilibrium lies to the left, in favor of the weaker acid and base.*

Reciprocal Relationship in Acid–Base Strength

One aid in predicting the relative strengths of conjugate acids and bases is the existence of a reciprocal relationship.

TOOLS

Reciprocal relationship

The stronger a Brønsted acid is, the weaker is its conjugate base.

To illustrate, recall that $HCl(g)$ is a very strong Brønsted acid; it's 100% ionized in a dilute aqueous solution.

$$HCl(g) + H_2O \xrightarrow{100\%} H_3O^+(aq) + Cl^-(aq)$$

As we explained in Chapter 5, we don't write double equilibrium arrows for the ionization of a strong acid. Not doing so with HCl is another way of saying that the chloride ion, the conjugate base of HCl, must be a very weak Brønsted–Lowry base. Even in the presence of H_3O^+, a very strong proton donor, chloride ions aren't able to win protons. So HCl, the strong acid, has a particularly weak conjugate base, Cl^-.

There's a matching reciprocal relationship.

The weaker a Brønsted acid is, the stronger is its conjugate base.

Consider, for example, the conjugate pair, OH^- and O^{2-}. The hydroxide ion is the conjugate acid and the oxide ion is the conjugate base. But the hydroxide ion must be an *extremely* weak Brønsted–Lowry acid; in fact, we've known it so far only as a base. Given the extraordinary weakness of OH^- as an acid, its conjugate base, the oxide ion, must be an exceptionally strong base. And as you've already learned, oxide ion is such a strong base that its reaction with water is 100% complete. That's why we don't write double equilibrium arrows in the equation for the reaction.

$$\underset{\text{base}}{O^{2-}} + \underset{\text{acid}}{H_2O} \xrightarrow{100\%} \underset{\text{acid}}{OH^-} + \underset{\text{base}}{OH^-}$$

The very strong base O^{2-} has a very weak conjugate acid, OH^-.

An amphoteric substance will act as a base if mixed with an acid, but it will act as an acid if mixed with a base. You might ask: If two amphoteric substances are mixed together, which will act as the acid and which as the base? The obvious answer is that the stronger acid will act as the acid and the other will be the base. In the reaction below, we find that the position of equilibrium lies to the left (with the reactants).

$$\underset{\text{acid}}{H_2S(aq)} + \underset{\text{base}}{HCO_3^-(aq)} \rightleftharpoons \underset{\text{base}}{HS^-(aq)} + \underset{\text{acid}}{H_2CO_3(aq)}$$

$\longleftarrow$

Position of equilibrium lies to the left.
HCO_3^- must be a weaker base than HS^-.

This can be interpreted as meaning that $H_2CO_3(aq)$ is a stronger acid than $H_2S(aq)$, which in turn makes $HCO_3^-(aq)$ a weaker base than $HS^-(aq)$. Therefore, if we mix a solution containing $HS^-(aq)$ with a solution containing $HCO_3^-(aq)$, the reaction will be

$$\underset{\text{base}}{HS^-(aq)} + \underset{\text{acid}}{HCO_3^-(aq)} \rightleftharpoons \underset{\text{acid}}{H_2S(aq)} + \underset{\text{base}}{CO_3^{2-}(aq)}$$

because the stronger base, HS^-, will remove the H^+ from the weaker base, HCO_3^-, causing the latter to actually behave as an acid.

Example 16.3

Using Reciprocal Relationships to Predict Equilibrium Positions

In the reaction below, will the position of equilibrium lie to the left or to the right, given the fact that acetic acid is known to be a stronger acid than the hydrogen sulfite ion?

$$HSO_3^-(aq) + C_2H_3O_2^-(aq) \rightleftharpoons HC_2H_3O_2(aq) + SO_3^{2-}(aq)$$

■ **Analysis:** In the equation above, the two acids are $HC_2H_3O_2$ and HSO_3^-. To find the answer to the question posed in the problem, we have to ask: How are the relative strengths of the acids related to where the position of equilibrium will be? The tools we select must relate to this issue.

■ **Assembling the Tools:** The position of an acid–base equilibrium favors the weaker acid and base. That's one of the tools we need to solve this problem. The other is the reciprocal relationship between the strengths of the members of a conjugate acid–base pair.

■ **Solution:** We'll write the equilibrium equation, using the given fact about the relative strengths of acetic acid and the hydrogen sulfite ion to start writing labels.

$$\underset{\text{weaker acid}}{HSO_3^-(aq)} + C_2H_3O_2^-(aq) \rightleftharpoons \underset{\text{stronger acid}}{HC_2H_3O_2(aq)} + SO_3^{2-}(aq)$$

Now we'll use our tool about the reciprocal relationships to label the two bases. The stronger acid must have the weaker conjugate base; the weaker acid must have the stronger conjugate base.

$$\underset{\text{weaker acid}}{HSO_3^-(aq)} + \underset{\text{weaker base}}{C_2H_3O_2^-(aq)} \rightleftharpoons \underset{\text{stronger acid}}{HC_2H_3O_2(aq)} + \underset{\text{stronger base}}{SO_3^{2-}(aq)}$$

Finally, because the position of equilibrium favors the weaker acid and base, the position of equilibrium lies to the left.

Is the Answer Reasonable? There are two things we can check. First, both of the weaker conjugates should be on the same side of the equation. They are, so that suggests we've made the correct assignments. Second, the reaction will proceed farther in the direction of the weaker acid and base, so that places the position of equilibrium on the left, which agrees with our answer.

Practice Exercises

16.9 | Given that HSO_4^- is a stronger acid than HPO_4^{2-}, what is the chemical reaction if solutions containing these ions are mixed together? (*Hint:* One of these must act as an acid and the other as a base.)

16.10 | Given that HSO_4^- is a stronger acid than HPO_4^{2-}, determine whether the substances on the left of the arrows or those on the right are favored in the following equilibrium.

$$HSO_4^-(aq) + PO_4^{3-}(aq) \rightleftharpoons SO_4^{2-}(aq) + HPO_4^{2-}(aq)$$

16.3 | Periodic Trends in the Strengths of Acids

In most cases, acids are formed by nonmetals, either in the form of solutions of their compounds with hydrogen [such as $HCl(aq)$] or as solutions of their oxides, which react with water to form oxoacids (such as H_2SO_4). The strengths of these acids vary in a systematic way with the location of the nonmetal in the periodic table.

Table 16.1 Acidic Binary Compounds of Hydrogen and Nonmetals[a]

Group 6A
(H_2O)
H_2S Hydrosulfuric acid
H_2Se Hydroselenic acid
H_2Te Hydrotelluric acid
Group 7A
HF Hydrofluoric acid
*HCl Hydrochloric acid
*HBr Hydrobromic acid
*HI Hydroiodic acid

[a] The *names* are for the aqueous solutions of these compounds. Strong acids are indicated with asterisks.

Trends in the Strengths of Binary Acids

Many (but not all) of the binary compounds between hydrogen and nonmetals, which we may represent by H*X* and H_2X, are acidic and are called **binary acids**. Table 16.1 lists those that are acids in water. The strong acids are marked by asterisks.

The relative strengths of binary acids correlate with the periodic table in two ways.

TOOLS

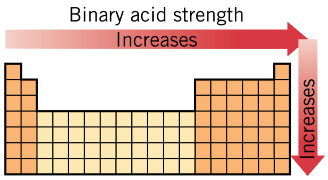
Periodic trends in strengths of binary acids

> The strengths of the binary acids increase from left to right within the same period.
> The strengths of binary acids increase from top to bottom within the same group.

Two factors can account for these variations. One is the electronegativity of the nonmetal *X*, and the other is the strength of the H—*X* bond.

Variations in electronegativity of the atom *X* alter the polarity of the H—*X* bond, so as *X* becomes more electronegative, the partial positive charge ($\delta+$) on H becomes greater. This makes it easier for the hydrogen to separate as H^+, so the molecule becomes a better proton donor.

A major influence on acidity is the strength of the H—*X* bond. Breaking this bond is essential for the hydrogen to separate as an H^+ ion, so anything that contributes to variations in bond strength will also affect variations in acid strength.



Going from left to right across a period, atomic size varies little, so the strengths of the H—*X* bonds are nearly the same. The major influence is the variation in the electronegativity of *X*, which increases from left to right. For example, as we go from left to right within Period 3, from S to Cl, the electronegativity increases and we find that HCl is a stronger acid than H_2S. A similar increase in electronegativity occurs going left to right in Period 2, from O to F, so HF is a stronger acid than H_2O.

In going down a group, there are two opposing factors. The electronegativity decreases, so the H—X bonds become less polar. At the same time, the atoms X become much larger, and this leads to a large drop in the H—X bond strength.[4] The variation in polarity tends to make the acids weaker, but the variation in bond strength tends to make them stronger. Changes in bond strength seem to win out, because the acids H_nX become stronger as we go down a group. For example, among the binary acids of the halogens the following order of relative acidity is observed.[5]

$$HF < HCl < HBr < HI$$

Thus, HF is the weakest acid in the series, and HI is the strongest. The identical trend occurs in the series of the binary acids of Group 6A elements, having formulas of the general type H_2X. Notice that these trends in acidity are the opposite of what we would expect on the basis of trends in electronegativities, which tell us that the H—F bond is more polar than the H—I bond and that the O—H bond is more polar than the H—S bond.

Practice Exercises

16.11 | Order the following groups of acids from the weakest to the strongest: (a) HI, HF, HBr; (b) HCl, PH_3, H_2S; (c) H_2Te, H_2O, H_2Se; (d) AsH_3, HBr, H_2Se; (e) HI, PH_3, H_2Se. (*Hint:* These are all binary acids.)

16.12 | Using *only* the periodic table, choose the stronger acid of each pair: (a) H_2Se or HBr, (b) H_2Se or H_2Te, (c) H_2O or H_2S.

Trends in the Strengths of Oxoacids

In Chapter 5 you learned that acids composed of hydrogen, oxygen, and some other element are called **oxoacids** (see Table 16.2). Those that are strong acids in water are identified in the table by asterisks.

Table 16.2 **Some Oxoacids of Nonmetals and Metalloids**[a]

Group 4A	Group 5A	Group 6A	Group 7A
H_2CO_3 Carbonic acid	*HNO_3 Nitric acid		HFO Hypofluorous acid
	HNO_2 Nitrous acid		
	H_3PO_4 Phosphoric acid	*H_2SO_4 Sulfuric acid	*$HClO_4$ Perchloric acid
	H_3PO_3 Phosphorous acid[b]	H_2SO_3 Sulfurous acid[c]	*$HClO_3$ Chloric acid
			$HClO_2$ Chlorous acid
			HClO Hypochlorous acid
	H_3AsO_4 Arsenic acid	*H_2SeO_4 Selenic acid	*$HBrO_4$ Perbromic acid[d]
	H_3AsO_3 Arsenous acid	H_2SeO_3 Selenous acid	*$HBrO_3$ Bromic acid
		$Te(OH)_6$ Telluric acid[e]	HIO_4 Periodic acid (H_5IO_6)[f]
		H_2TeO_3 Tellurous acid	HIO_3 Iodic acid

[a] Strong acids are indicated with asterisks.

[b] Phosphorous acid, despite its formula, is only a diprotic acid.

[c] Hypothetical. An aqueous solution actually contains just dissolved sulfur dioxide, $SO_2(aq)$.

[d] Pure perbromic acid is unstable; a dihydrate is known.

[e] $Te(OH)_6$ is a diprotic acid.

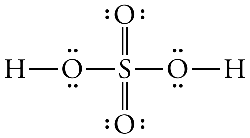
[f] H_5IO_6 is formed from $HIO_4 + 2H_2O$.

---

[4] Small atoms tend to form stronger bonds than large atoms, so as we go down a group there is a rapid decrease in the H—X bond strength as the atoms X become larger.

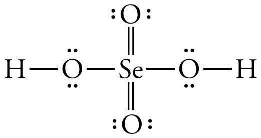
[5] We compare acid strengths by the acid's ability to donate a proton to a particular base. As we noted earlier, for strong acids such as HCl, HBr, and HI, water is too strong a proton acceptor to permit us to see differences among their proton-donating abilities. All three of these acids are completely ionized in water and so appear to be of equal strength, a phenomenon called the *leveling effect* (the differences are obscured or *leveled* out). To compare the acidities of these acids, a solvent that is a weaker proton acceptor than water (liquid HF or $HC_2H_3O_2$, for example) has to be used.

A feature common to the structures of all oxoacids is the presence of O—H groups bonded to some central atom. For example, the structures of two oxoacids of the Group 6A elements are



H_2SO_4

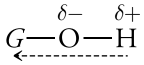
sulfuric acid



H_2SeO_4

selenic acid

When an oxoacid ionizes, the hydrogen that's lost as an H^+ comes from the same kind of bond in every instance—specifically, an O—H bond. The "acidity" of such a hydrogen, meaning the ease with which it's released as H^+, is determined by how the group of atoms attached to the oxygen affects the polarity of the O—H bond. If this group of atoms makes the O—H bond more polar, it will cause the H to come off more easily as H^+ and thereby increase the acidity of the molecule.

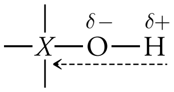


If the group of atoms, *G*, attached to the O—H group is able to draw electron density from the O atom, the O will pull electron density from the O—H bond, thereby making the bond more polar.

It turns out that there are two principal factors that determine how the polarity of the O—H bond is affected. One is the electronegativity of the central atom in the oxoacid and the other is the number of oxygens attached to the central atom.

Effect of the Electronegativity of the Central Atom

To study the effects of the electronegativity of the central atom, we must compare oxoacids having the same number of oxygens. When we do this, we find that as the electronegativity of the central atom increases, the oxoacid becomes a better proton donor (i.e., a stronger acid). The following diagram illustrates the effect.



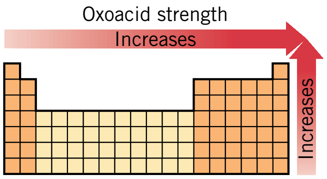
As the electronegativity of *X* increases, electron density is drawn away from O, which draws electron density away from the O—H bond. This makes the bond more polar and makes the molecule a better proton donor.

Because electronegativity increases from bottom to top within a group and from left to right within a period, we can make the following generalization.

TOOLS

Trends in the strengths of oxoacids

> When the central atoms of oxoacids hold the same number of oxygen atoms, the acid strength increases from bottom to top within a group and from left to right within a period.



In Group 6A, for example, H_2SO_4 is a stronger acid than H_2SeO_4 because sulfur is more electronegative than selenium. Similarly, among the halogens, acid strength increases for acids with the formula HXO_4 as follows:

$$HIO_4 < HBrO_4 < HClO_4$$

Going from left to right within Period 3, we can compare the acids H_3PO_4, H_2SO_4, and $HClO_4$, where we find the following order of acidities.

$$H_3PO_4 < H_2SO_4 < HClO_4$$

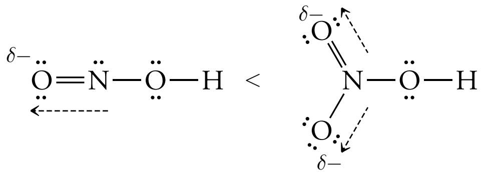
Practice Exercises

16.13 | Which is the stronger acid: (a) $HClO_3$ or $HBrO_3$, (b) H_3PO_4 or H_2SO_4? (*Hint:* Note that each pair has the same number of oxygen atoms.)

16.14 | In each pair indicate the weaker acid: (a) H_3PO_4 or H_3AsO_4, (b) HIO_4 or H_2TeO_4.

Effect of the Number of Oxygens Bound to the Central Atom

Comparing oxoacids with the same central atom, we find that as the number of *lone oxygens* increases, the oxoacid becomes a better proton donor. (A *lone oxygen* is one that is bonded only to the central atom and not to a hydrogen.) Thus, comparing HNO_3 with HNO_2, we find that HNO_3 is the stronger acid. To understand why, let's look at their molecular structures.



nitrous acid　　nitric acid

In an oxoacid, lone oxygens pull electron density away from the central atom, which increases the central atom's ability to draw electron density away from the O—H bond. It's as though the lone oxygens make the central atom more electronegative. Therefore, the more lone oxygens that are attached to a central atom, the more polar will be the O—H bonds of the acid and the stronger will be the acid. Thus, the two lone oxygens in HNO_3 produce a greater effect than the one lone oxygen in HNO_2, so HNO_3 is the stronger acid.

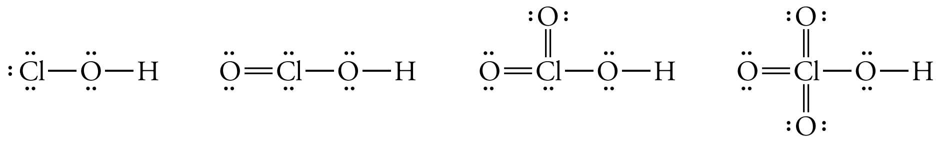
■ Oxygen is the second most electronegative element and has a strong tendency to pull electron density away from any atom to which it is attached.

Similar effects are seen among other oxoacids, as well. For the oxoacids of chlorine, for instance, we find the following trend:

$$HClO < HClO_2 < HClO_3 < HClO_4$$

Comparing their structures, we have

■ Usually, the formula for hypochlorous acid is written HOCl to reflect its molecular structure. We've written it HClO here to make it easier to follow the trend in acid strengths among the oxoacids of chlorine.



HClO　　$HClO_2$　　$HClO_3$　　$HClO_4$

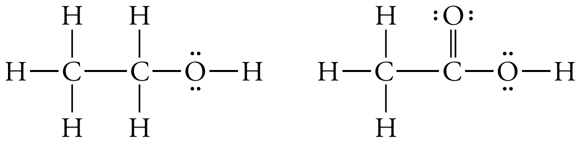
This leads to another generalization.

> For a given central atom, the acid strength of an oxoacid increases with the number of oxygens held by the central atom.

TOOLS

Trends in the strengths of oxoacids

The ability of lone oxygens to affect acid strength extends to organic compounds as well. For example, compare the molecules below.

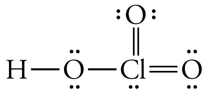


ethanol　　acetic acid

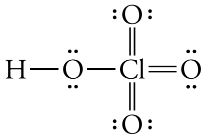
In water, ethanol (ethyl alcohol) is not acidic at all. Replacing the two hydrogens on the carbon adjacent to the OH group with an oxygen, however, yields acetic acid. The greater ability of oxygen to pull electron density from the carbon produces a greater polarity of the O—H bond, which is one factor that causes acetic acid to be a better proton donor than ethanol.

The Reciprocal Relationship—A Molecular Interpretation

On page 748 we noted the reciprocal relationship between the strength of an acid and that of its conjugate base. For oxoacids, the lone oxygens play a part in determining the basicity of the anion formed in the ionization reaction. Consider the acids $HClO_3$ and $HClO_4$.

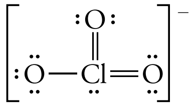


$HClO_3$

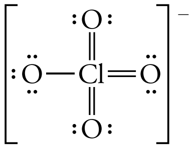


$HClO_4$

From our earlier discussion, we expect $HClO_4$ to be a stronger acid than $HClO_3$, which it is. Ionizations of their protons yield the anions ClO_3^- and ClO_4^-.



ClO_3^-



ClO_4^-

In an **oxoanion** (an anion formed from an oxoacid) the *lone* oxygens carry most of the negative charge, which is delocalized over the lone oxygens. In the ClO_3^- ion, the single negative charge is spread over three oxygens, so each carries a charge of about $\frac{1}{3}-$. This is not a *formal* charge obtained by the rules on page 389. We're saying that the 1− charge on the ion is delocalized over three oxygens to give each an actual charge of $\frac{1}{3}-$. By the same reasoning, in the ClO_4^- ion each oxygen carries a charge of about $\frac{1}{4}-$. The smaller negative charge on the oxygens in ClO_4^- makes this ion less able than ClO_3^- to attract H^+ ions from H_3O^+, so ClO_4^- is a weaker base than ClO_3^-. Thus, the anion of the stronger acid is the weaker base.

■ The concept of delocalization of electrons to provide stability was presented in Section 10.8.

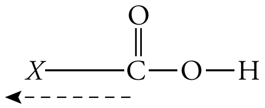
Practice Exercises

16.15 | In each pair, select the stronger acid: (a) HIO_3 or HIO_4, (b) H_2TeO_3 or H_2TeO_4, (c) H_3AsO_3 or H_3AsO_4. (*Hint:* This problem focuses on the effect of oxygen atoms in acids.)

16.16 | In each pair, select the weaker acid: (a) H_2SO_4 or $HClO_4$, (b) H_3AsO_4 or H_2SO_4.

Strengths of Organic Acids

On page 753 we noted that replacing two H atoms in an alcohol by a lone oxygen causes the resulting molecule to be acidic. The acidity of the molecule can be increased further if other electronegative groups such as halogens are bonded to carbon atoms near the —CO_2H group of the acid. Such a group, labeled *X* below, pulls electron density from the carbon atom of the carboxyl group, further increasing the polarity of the O—H bond. This causes an increase in the acidity of the molecule.



$$X\text{———}\overset{\overset{\displaystyle O}{\|}}{C}-O-H$$

As the ability of *X* to draw electrons away from C increases, the polarity of the O—H bond increases and the molecule becomes more acidic.

Thus, chloroacetic acid is a stronger acid than acetic acid, and dichloroacetic acid and trichloroacetic acids are increasingly stronger acids.

$$CH_3CO_2H < CH_2ClCO_2H < CHCl_2CO_2H < CCl_3CO_2H$$

Addition of each chlorine effectively withdraws more electron density from the O—H bond, resulting in a weaker bond and a stronger acid.

Practice Exercises

16.17 | How would you expect the acidities of the following molecules to compare?

16.4 | Lewis Definition of Acids and Bases

In our preceding discussions, acids and bases have been characterized by their tendency to lose or gain protons. However, there are many reactions not involving proton transfer that have properties we associate with acid–base reactions. For example, if gaseous SO_3 is passed over solid CaO, a reaction occurs in which $CaSO_4$ forms.

$$CaO(s) + SO_3(g) \longrightarrow CaSO_4(s) \qquad \textbf{(16.2)}$$

If these reactants are dissolved in water first, they react to form $Ca(OH)_2$ and H_2SO_4, and when their solutions are mixed the following reaction takes place.

$$Ca(OH)_2(aq) + H_2SO_4(aq) \longrightarrow CaSO_4(s) + 2H_2O \qquad \textbf{(16.3)}$$

The same two initial reactants, CaO and SO_3, form the same ultimate product, $CaSO_4$. It certainly seems that if Reaction 16.3 is an acid–base reaction, we should be able to consider Reaction 16.2 to be an acid–base reaction, too. But there are no protons being transferred, so our definitions require further generalizations. These were provided by G. N. Lewis, after whom Lewis symbols are named.

Lewis Definitions of Acids and Bases

1. A **Lewis acid** is any ionic or molecular species that can accept a pair of electrons in the formation of a coordinate covalent bond.
2. A **Lewis base** is any ionic or molecular species that can donate a pair of electrons in the formation of a coordinate covalent bond.
3. **Neutralization** is the formation of a coordinate covalent bond between the donor (base) and the acceptor (acid).

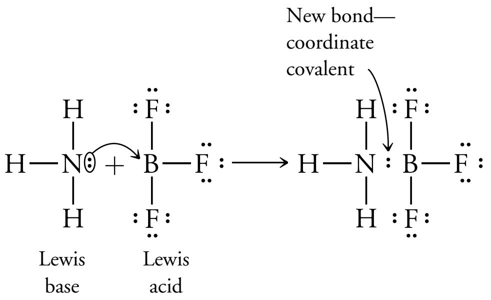
TOOLS

Lewis acid–base definitions

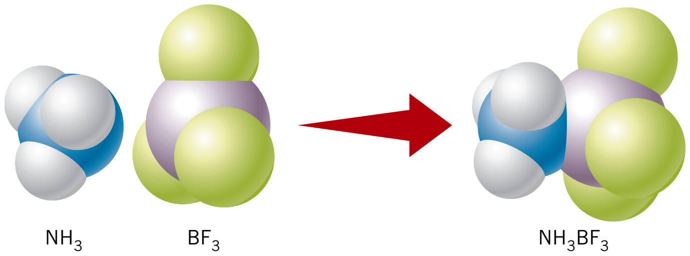
■ Remember, a coordinate covalent bond is just like any other covalent bond once it has formed. By using this term, we are following the origin of the electron pair that forms the bond.

Examples of Lewis Acid–Base Reactions

The reaction between BF_3 and NH_3 illustrates a Lewis acid–base neutralization. The reaction is exothermic because a bond is formed between N and B, with the nitrogen donating an electron pair and the boron accepting it.



New bond—
coordinate
covalent
Lewis
base
Lewis
acid



NH_3
BF_3
NH_3BF_3

Note that as the bond forms from ammonia to boron trifluoride, the geometry around the boron changes from planar triangular to tetrahedral, which is what is expected with four bonds to the boron.

■ A similar reaction was described in Chapter 9 between BCl_3 and ammonia. Compounds like BF_3NH_3, which are formed by simply joining two smaller molecules, are called **addition compounds.**

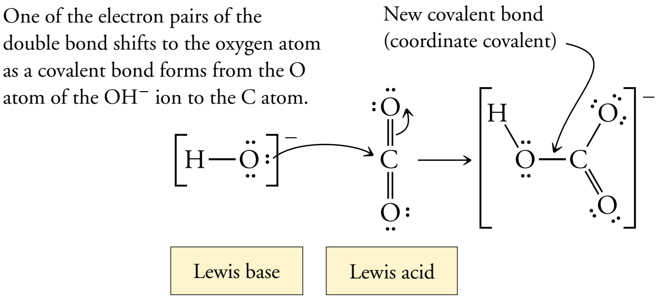
The ammonia molecule thus acts as a *Lewis base*. The boron atom in BF_3, having only six electrons in its valence shell and needing two more to achieve an octet, accepts the pair of electrons from the ammonia molecule. Hence, BF_3 is functioning as a *Lewis acid*.

As this example illustrates, Lewis bases are substances that have completed valence shells *and unshared pairs of electrons* (e.g., NH_3, H_2O, and O^{2-}). A Lewis acid, on the other hand, can be a substance with an incomplete valence shell, such as BF_3 or H^+.

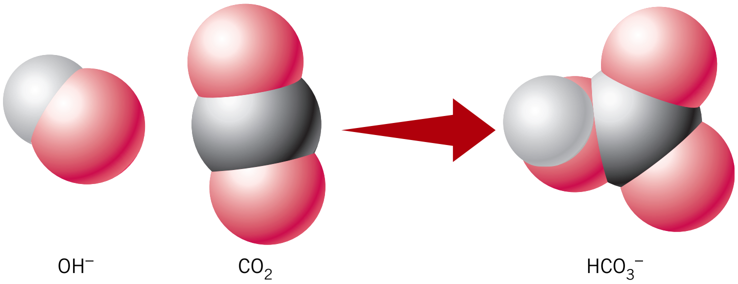
A substance can also be a Lewis acid even when it has a central atom with a complete valence shell. This works when the central atom has a double bond that, by the shifting of an electron pair to an adjacent atom, can make room for an incoming pair of electrons from a Lewis base. Carbon dioxide is an example. When carbon dioxide is bubbled into aqueous sodium hydroxide, the gas is instantly trapped as the bicarbonate ion.

$$CO_2(g) + OH^-(aq) \longrightarrow HCO_3^-(aq)$$

Lewis acid–base theory represents the movement of electrons in this reaction as follows.



One of the electron pairs of the double bond shifts to the oxygen atom as a covalent bond forms from the O atom of the OH⁻ ion to the C atom.
New covalent bond
(coordinate covalent)
Lewis base
Lewis acid

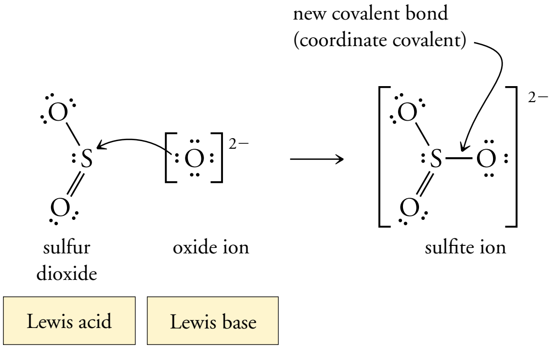


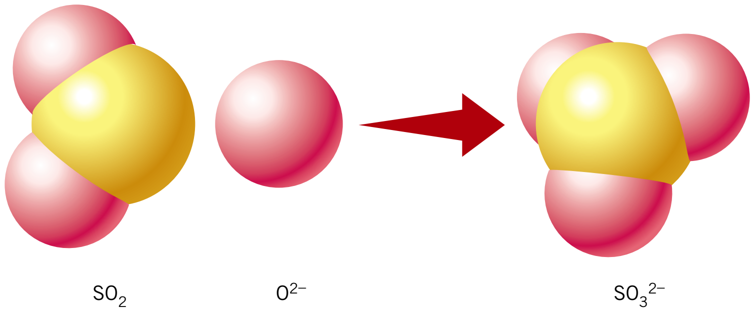
The donation of an electron pair *from* the oxygen of the OH^- ion produces a bond, so the OH^- ion is the Lewis base. The carbon atom of the CO_2 accepts the electron pair, so CO_2 is the Lewis acid.

Lewis acids can also be substances that have valence shells capable of holding more electrons. For example, consider the reaction of sulfur dioxide as a Lewis acid with oxide ion as a Lewis base to make the sulfite ion. This reaction occurs when gaseous sulfur dioxide, an acidic anhydride, mingles with solid calcium oxide, a basic anhydride, to give calcium sulfite, $CaSO_3$.

$$SO_2(g) + CaO(s) \longrightarrow CaSO_3(s)$$

Let's see how electrons relocate as the sulfite ion forms. We use one of the two resonance structures of SO_2 and one of the three such structures for the sulfite ion.





The two very electronegative oxygens attached to the sulfur in SO_2 give the sulfur a substantial positive partial charge, which induces the formation of the coordinate covalent bond from the oxide ion to the sulfur. In this case, sulfur can accommodate more than an octet in its valence shell, so relocation of electron pairs is not necessary.

In the chapter opening photograph we described some of the chemistry involved in steelmaking by the *basic oxygen process*. In this process, O_2 is blown through the molten steel mixture, causing carbon and other nonmetals to be oxidized. Silicon, for example, is oxidized to SiO_2 and must be removed from the steel. To accomplish this, calcium oxide is added that reacts with the silicon dioxide to form calcium silicate.

$$\underset{\text{calcium oxide}}{CaO(s)} + \underset{\text{silicon dioxide}}{SiO_2(l)} \longrightarrow \underset{\text{calcium silicate}}{CaSiO_3(l)}$$

This is a reaction between the Lewis base O^{2-} and the Lewis acid SiO_2. At the molecular level the reaction is complex because SiO_2 is the empirical formula for a polymeric oxide containing oxygen bridges between silicon atoms; the structure of the product is similarly complicated. At the high temperature of the furnace, the product is a liquid called *slag*, which is easily separated from the steel.

Table 16.3 summarizes the kinds of substances that behave as Lewis acids and bases. Study the table and then work on the Practice Exercises below.

Table 16.3 **Types of Substances that Are Lewis Bases**

Lewis Acids
Molecules or ions with incomplete valence shells (e.g., BF_3, H^+)
Molecules or ions with complete valence shells, but with multiple bonds that can be shifted to make room for more electrons (e.g., CO_2)
Molecules or ions that have central atoms capable of holding additional electrons (usually, atoms of elements in Periods 3 through 7) (e.g., SO_2)
Lewis Bases
Molecules or ions that have unshared pairs of electrons and that have complete valence shells (e.g., O^{2-}, NH_3)

Practice Exercises

16.18 | Identify the Lewis acid and base in each reaction.

(a) $NH_3 + H^+ \rightleftharpoons NH_4^+$

(b) $SeO_3 + Na_2O \rightleftharpoons Na_2SeO_4$

(c) $Ag^+ + 2NH_3 \rightleftharpoons Ag(NH_3)_2^+$

(*Hint:* Draw Lewis structures of the reactants.)

16.19 | (a) Is the fluoride ion more likely to behave as a Lewis acid or a Lewis base? Explain. (b) Is the $BeCl_2$ molecule more likely to behave as a Lewis acid or a Lewis base? Explain. (c) Is the SO_3 molecule more likely to behave as a Lewis acid or a Lewis base? Explain.

Interpreting Brønsted–Lowry Acid–Base Reactions Using the Lewis Acid–Base Concept

Reactions involving the transfer of a proton can be analyzed by either the Brønsted–Lowry or Lewis definitions of acids and bases. Consider, for example, the reaction between hydronium ion and ammonia in aqueous solution.

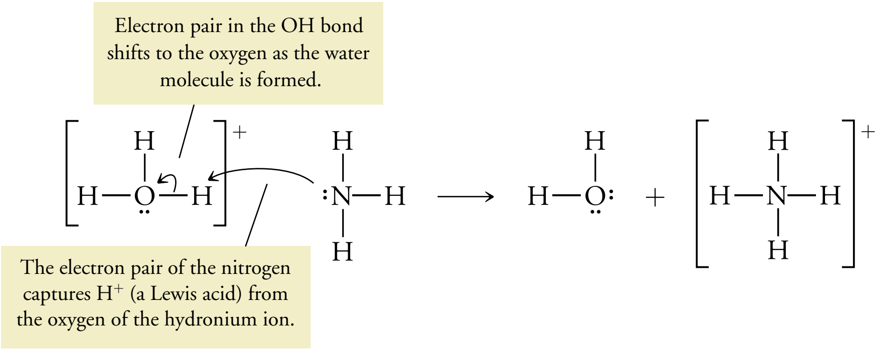
$$H_3O^+ + NH_3 \longrightarrow H_2O + NH_4^+$$

Applying the Brønsted–Lowry definitions, we have an acid, H_3O^+, reacting with a base, NH_3, to give the corresponding conjugates: H_2O being the conjugate base of H_3O^+ and NH_4^+ being the conjugate acid of NH_3.

To interpret this reaction using the Lewis definitions, we view it as the movement of a Lewis acid (the proton, H^+) from a weaker Lewis base (H_2O) to a stronger Lewis base (NH_3). In other words, we view the hydronium ion as the "neutralization" product of the Lewis base H_2O with the Lewis acid H^+. To emphasize that it is the proton that is transferring, we might write the equation as

$$H_2O—H^+ + NH_3 \longrightarrow H_2O + H^+—NH_3$$

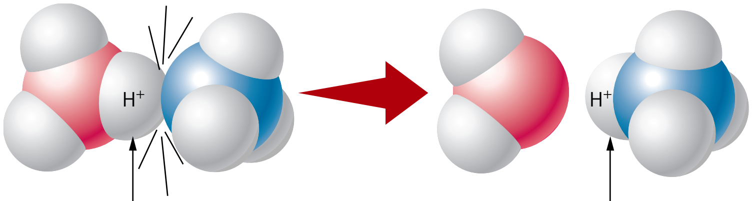
We can diagram this as follows using Lewis structures:



Electron pair in the OH bond shifts to the oxygen as the water molecule is formed.

The electron pair of the nitrogen captures H^+ (a Lewis acid) from the oxygen of the hydronium ion.

The molecular view of the reaction is



During a collision, a proton (Lewis acid) transfers from one Lewis base (water) to another Lewis base (ammonia).

In general, all Brønsted–Lowry acid–base reactions can be analyzed from the Lewis point of view following this same pattern, with the position of equilibrium favoring the proton being attached to the stronger Lewis base.

A word of caution is in order here. In analyzing proton transfer reactions, it is wise to stick to one interpretation or the other (Brønsted–Lowry or Lewis). Usually we will use the Brønsted–Lowry approach because it is useful to think in terms of conjugate acid–base pairs. However, if you switch to the Lewis interpretation, don't try to apply Brønsted–Lowry terminology at the same time; it won't work and you'll only get confused.

16.5 | Acid–Base Properties of Elements and Their Oxides

The elements most likely to form acids are the nonmetals in the upper right-hand corner of the periodic table. Those most likely to form basic hydroxides are similarly grouped in one general location in the table, among the metals, particularly those in Groups 1A (alkali metals) and 2A (alkaline earth metals). Thus, elements can themselves be classified according to their abilities to be involved in acids or bases.

In general, the experimental basis for classifying an element according to its abilities to form an acid or base depends on how its *oxide* behaves toward water. Earlier you learned that metal oxides like Na_2O and CaO are called *basic anhydrides* ("anhydride" means "without water") because they react with water to form hydroxides.

$$Na_2O + H_2O \longrightarrow 2NaOH \qquad \text{sodium hydroxide}$$
$$CaO + H_2O \longrightarrow Ca(OH)_2 \qquad \text{calcium hydroxide}$$

The reactions of metal oxides with water are really reactions of their oxide ions, which take H^+ from molecules of H_2O, leaving ions of OH^-.

Many metal oxides are insoluble in water, so their oxide ions are unable to take H^+ ions from H_2O molecules. Many are able to react with acids, which attack the oxide ions in the solid. Iron(III) oxide, for example, reacts with acid as follows.

$$Fe_2O_3(s) + 6H^+(aq) \longrightarrow 2Fe^{3+}(aq) + 3H_2O$$

This is a common method for removing rust from iron in industrial processes.

Nonmetal oxides are usually *acidic anhydrides;* those that react with water give acidic solutions. Typical examples of the formation of acids from nonmetal oxides are the following reactions.

$$SO_3(g) + H_2O \longrightarrow H_2SO_4(aq) \qquad \text{sulfuric acid}$$
$$N_2O_5(g) + H_2O \longrightarrow 2HNO_3(aq) \qquad \text{nitric acid}$$
$$CO_2(g) + H_2O \longrightarrow H_2CO_3(aq) \qquad \text{carbonic acid}$$

Acidity of Hydrated Metal Ions

■ The force of attraction between an ion and water molecules is often strong enough to persist when the solvent water evaporates. Solid *hydrates* crystallize from solution, for example, $CuSO_4 \cdot 5H_2O$ (page 14).

When an ionic compound dissolves in water, molecules of the solute gather around the ions and we say the ions are *hydrated*. Within a hydrated cation, the metal ion behaves as a Lewis acid, binding to the partial negative charges on the oxygens of the surrounding water molecules, which serve as Lewis bases. Hydrated metal ions themselves tend to be Brønsted acids because of the equilibrium shown below. For simplicity, the equation represents a metal ion as a *mono*hydrate—namely, $M(H_2O)^{n+}$ with a net positive charge of $n+$ (n being 1, 2, or 3, depending on M).

$$M(H_2O)^{n+} + H_2O \rightleftharpoons MOH^{(n-1)+} + H_3O^+$$

In other words, hydrated metal ions tend to be proton donors in water. Let's see why.

The positive charge on the metal ion attracts the water molecule and draws electron density from the O—H bonds, causing them to become more polar (Figure 16.3). This increases the partial positive charge on H and weakens the O—H bond with respect to the transfer of H^+ to another nearby water molecule in the formation of a hydronium ion. The entire process can be illustrated as follows.

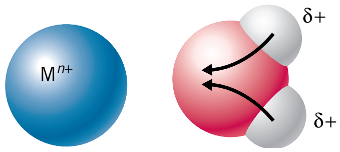


Figure 16.3 | **Polarization of a water molecule by a metal cation.** The positive charge on the metal ion pulls electron density away from the H atoms of the water molecule. This increases the partial positive charge on the H atoms and makes them easier to transfer to another H_2O molecule nearby.

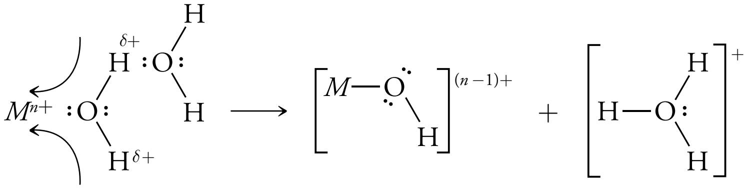
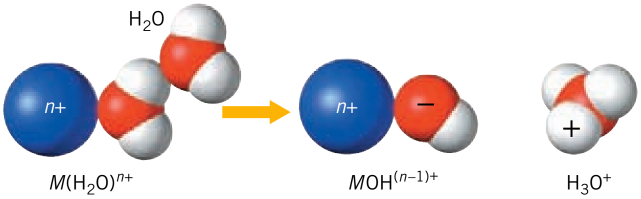


Electron density is reduced in the O—H bonds of water (indicated by the curved arrows) by the positive charge of the metal ion, thereby increasing the partial positive charge on the hydrogens. This promotes the transfer of H^+ to a water molecule.



The degree to which metal ions produce acidic solutions depends primarily on two things: the amount of charge on the metal ion and the metal ion's size. As the metal ion's charge increases, the polarizing effect is increased, which thereby favors the release of H^+. This means that highly charged metal ions ought to produce solutions that are more acidic than ions of lower charge, and that is generally the case.

The size of the cation also affects its acidity because when the cation is small, the positive charge is highly concentrated. A highly concentrated positive charge is better able to pull electrons from an O—H bond than a positive charge that is more spread out. Therefore, for a given positive charge, the smaller the cation, the more acidic are its solutions.

Both size and amount of charge can be considered simultaneously by referring to a metal ion's *positive charge density*, the ratio of the positive charge to the volume of the cation (its ionic volume).

$$\text{Charge density} = \frac{\text{ionic charge}}{\text{ionic volume}}$$

TOOLS

Acidity of metal cations

The higher the positive charge density, the more effective the metal ion is at drawing electron density from the O—H bond and the more acidic is the hydrated cation.

Very small cations with large positive charges have large positive charge densities and tend to be quite acidic. An example is the hydrated aluminum ion, Al^{3+}. The hexahydrate, $Al(H_2O)_6{}^{3+}$, is one of several of this cation's hydrated forms that are present in an aqueous

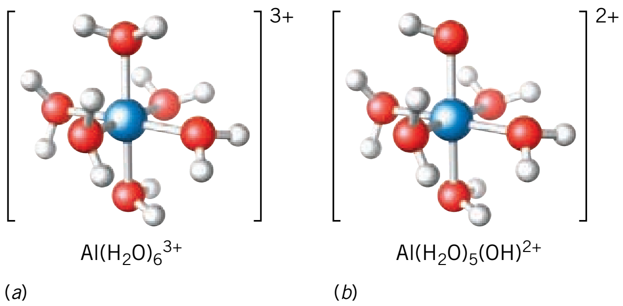


Figure 16.4 | **Hydrated aluminum ion is a weak proton donor in water.** (*a*) The highly charged Al^{3+} ion (blue) binds six water molecules in an aqueous solution to give an octahedral structure with the formula $Al(H_2O)_6^{3+}$. (*b*) When it donates a proton, the ion loses one unit of positive charge as a water molecule is transformed into a hydroxide ion, shown at the top of the structure. The resulting ion now has the formula $Al(H_2O)_5(OH)^{2+}$.

solution of an aluminum salt (see Figure 16.4). The ion is acidic in water because of the equilibrium

$$Al(H_2O)_6^{3+}(aq) + H_2O \rightleftharpoons Al(H_2O)_5(OH)^{2+}(aq) + H_3O^+(aq)$$

The equilibrium, while not actually *strongly* favoring the products, does produce enough hydronium ion so that a 0.1 *M* solution of $AlCl_3$ in water has about the same concentration of hydronium ions as a 0.1 *M* solution of acetic acid, roughly 1×10^{-3} *M*.

Periodic Trends in the Acidity of Metal Ions

Within the periodic table, atomic size increases down a group and decreases from left to right in a period. Cation sizes follow these same trends, so within a given group, the cation of the metal at the top of the group has the smallest volume and the largest charge density. Therefore, hydrated metal ions at the top of a group in the periodic table are the most acidic within the group.

The cations of the Group 1A metals (Li^+, Na^+, K^+, Rb^+, and Cs^+), with charges of just 1+, have little tendency to increase the H_3O^+ concentration in an aqueous solution.

Within Group 2A, the Be^{2+} cation is very small and has sufficient charge density to cause the hydrated ion to be a weak acid. The other cations of Group 2A (Mg^{2+}, Ca^{2+}, Sr^{2+}, Ba^{2+}), have charge densities that become progressively smaller as we go down the group. Although their hydrated ions all generate some hydronium ion in water, the amount is negligible.

Some transition metal ions are also acidic, especially those with charges of 3+. For example, solutions containing salts of Fe^{3+} and Cr^{3+} tend to be acidic because their ions in solution exist as $Fe(H_2O)_6^{3+}$ and $Cr(H_2O)_6^{3+}$, respectively, and undergo the same ionization reaction as does the $Al(H_2O)_6^{3+}$ ion discussed previously.

Influence of Oxidation Number on the Acidity of Metal Oxides

Not all metal oxides are basic. As the oxidation number (or charge) on a metal ion increases, the metal ion becomes more *acidic*; it becomes a better electron pair acceptor. For metal hydrates, we've seen that this causes electron density to be pulled from the OH bonds of water molecules, causing the hydrate itself to become a weak proton donor. The increasing acidity of metal ions with increasing charge also affects the basicity of their oxides.

When the positive charge on a metal is small, the oxide tends to be basic, as we've seen for oxides such as Na_2O and CaO. With ions having a 3+ charge, the oxides are less basic and begin to take on acidic properties as well; they become amphoteric. (Recall from Section 16.1 that a substance is *amphoteric* if it is capable of reacting as either an acid or a base.) Aluminum oxide is an example; it can react with both acids and bases. It has basic properties when it dissolves in acid.

$$Al_2O_3(s) + 6H^+(aq) \longrightarrow 2Al^{3+}(aq) + 3H_2O$$

As noted earlier, the hydrated aluminum ion has six water molecules surrounding it, so in an acidic solution the aluminum exists primarily as $Al(H_2O)_6^{3+}$.

Aluminum oxide exhibits acidic properties when it dissolves in a base. One way to write the equation for the reaction is

$$Al_2O_3(s) + 2OH^-(aq) \longrightarrow 2AlO_2^-(aq) + H_2O$$

Actually, in basic solution the formula of the aluminum-containing species is more complex than this and is better approximated by $Al(H_2O)_2(OH)_4^-$. Note that the difference between the two formulas is just the number of water molecules involved in the formation of the ion.

$$Al(H_2O)_2(OH)_4^- \text{ is equivalent to } AlO_2^- + 4H_2O$$

However we write the formula for the aluminum-containing ion, it is an anion, not a cation.

When the metal is in a very high oxidation state, the oxide becomes acidic. Chromium(VI) oxide, CrO_3, is an example. When dissolved in water, the resulting solution is quite acidic and is called chromic acid. One of the principal species in the solution is H_2CrO_4, which is a strong acid that is more than 95% ionized. The acid forms salts containing the chromate ion, CrO_4^{2-}.

16.6 | Advanced Ceramics and Acid–Base Chemistry

Ceramic materials have a long history, dating to prehistoric times. Examples of pottery about 13,000 years old have been found in several parts of the world. Today, manufactured ceramics include common inorganic building materials such as brick, cement, and glass. We find ceramics around the home as porcelain dinnerware, tiles, sinks, toilets, and artistic pottery and figurines. These materials are made from inorganic minerals such as clay, silica (sand), and other silicates (compounds containing anions composed of silicon and oxygen), which are taken from the earth's crust.

In recent times, an entirely new set of materials, generally referred to as *advanced ceramics,* have been prepared by chemists in laboratories and have high-tech applications. We find such ceramics in places we wouldn't expect, such as in cell phones and inside diesel engines.

Several methods are used to form ceramics from their raw materials. In many cases, the components of the ceramic are first pulverized to give a very fine powder. The powder is then mixed with water to form a slurry that can be poured into a mold where it sets up into a solid form that has little structural strength. (Alternatively, the fine powder is mixed with a binder and pressed into the desired shape.) The newly formed object is next placed in a kiln where it is heated to a high temperature, often over 1000 °C. At these high temperatures the fine particles stick together by a process called **sintering**, which produces the finished ceramic. Although sintering is sometimes accompanied by partial melting of the fine particles, often the particles remain entirely solid during the process.

There are some problems with making ceramics by the traditional methods just described. Because it is difficult to produce uniform and very small particle sizes by grinding, ceramics made from materials prepared this way often contain small cracks and voids, which adversely affect physical properties such as strength. In addition, the chemical composition of the ceramic cannot be easily and reproducibly controlled by mixing various powdered components.

The Sol-Gel Process

For some types of ceramics, the problems of particle size and uniformity can be avoided by using a method called the **sol-gel process**. The chemistry involved is based on acid–base reactions similar to those discussed earlier in this chapter. The starting materials are metal salts or compounds in which a metal or metalloid (e.g., Si) is bonded to some number of

CHEMISTRY OUTSIDE THE CLASSROOM 16.1

Applications of Advanced Ceramic Materials

There are some properties that all ceramics have in common, and there are others that can be tailored by controlling the ceramic's composition and method of preparation. For example, virtually all ceramic materials have extremely high melting points and are much harder than steel. Some, such as boron nitride, BN, are nearly as hard as diamond, the hardest substance known. Silicon carbide, SiC, is a hard and relatively inexpensive ceramic to make in bulk and has long been used as an abrasive in sandpaper and grinding wheels.

The high strength and relatively low density of ceramic materials make them useful for applications in space. They are used to line the surfaces of rocket engines because they transmit heat very slowly and are able to protect the metals used to construct the engines from melting. The exterior of the space shuttle (Figure 1) is coated with protective ceramic tiles that serve as thermal "heat" shields during re-entry from space. The tiles are made of a low-density porous silica ceramic derived from common sand, SiO_2. They are able to withstand very high temperatures and have a very low thermal conductivity, preventing heat transfer to the body of the shuttle.

High-tech ceramics are relatively new materials, and new applications for them are continually being found. It is interesting to note how varied their uses are. Here are a few examples.

Thin ceramic films, deposited by the sol-gel process or other methods, are found on optical surfaces where they serve as antireflective coatings and as filters for lighting. Tools such as drill bits are given thin coatings of titanium nitride (TiN) to make them more wear resistant (Figure 2).

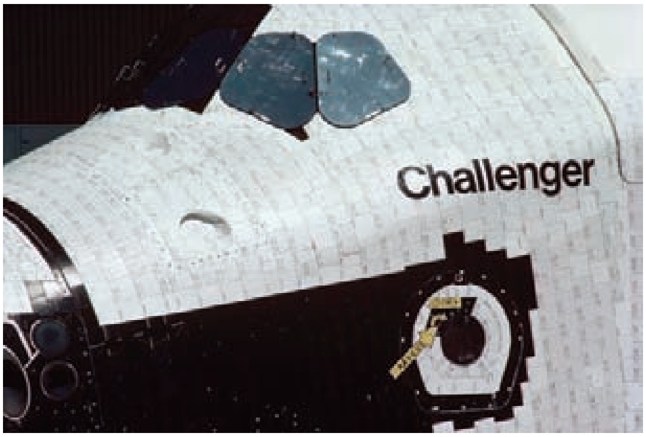

Figure 1 **Space shuttle heat shield.** Individual heat-shielding ceramic tiles are visible on the surface of the space shuttle *Challenger*. The photo was taken shortly after the spacecraft was completed. In 1986, the *Challenger* was lost in a tragic accident shortly after lift-off. Damage to the tiles during liftoff is believed to be responsible for the loss of the *Columbia* and its crew in February 2003 when the spacecraft broke apart during reentry into the earth's atmosphere. *(Roger Ressmeyer/© Corbis)*

Zirconia (ZrO_2) is used to make ceramic golf spikes for golf shoes, as well as portions of hip-joint replacement parts for medicine and knives that stay sharp much longer than steel. All these applications are possible because of the hardness of the ZrO_2 ceramic.

Boron nitride (BN) powder is composed of flat, plate-like crystals that can easily slide over one another, and one of its uses is in cosmetics, where it gives a silky texture to the product (Figure 3). Another boron-containing ceramic, boron carbide, is used along with Kevlar polymer to make bulletproof vests. When a bullet strikes the vest, it is shattered by the ceramic, which absorbs most of the kinetic energy, with residual energy being absorbed by the Kevlar backing.

Figure 2 **Titanium nitride.** A drill bit with a thin golden coating of titanium nitride, TiN, will retain its sharpness longer than steel drill bits. *(Andy Washnik)*

Silicon nitride, Si_3N_4, is used to make engine components for diesel engines because it is extremely hard and wear resistant, has a high stiffness with low density, and can withstand extremely high temperatures and harsh chemical environments.

Piezoelectric ceramics have the property that they produce an electric potential when their shape is deformed. Conversely, they deform when an electric potential is applied to them. A company makes "smart skis" that incorporate piezoelectric devices that use both properties. Vibrations in the skis are detected by the potential developed when they deform. A potential is then applied to cancel the vibration. This "smart materials" technology was first developed to dampen vibrations in optical components of the "Star Wars" weapons system designed to protect the United States from missile attack.

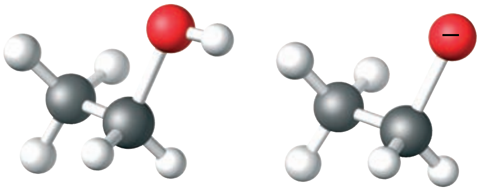
alkoxide groups. An *alkoxide* is an anion formed by removing a hydrogen ion from an alcohol.[6] For instance, removal of H^+ from ethanol yields the ethoxide ion.

$$\underset{\text{ethanol}}{C_2H_5OH} \xrightarrow{-H^+} \underset{\text{ethoxide ion}}{C_2H_5O^-}$$



The ethoxide ion forms salts with metal ions that generally are soluble in ethanol, which should not be surprising considering the similarities between the solute and solvent.

Alcohols are extremely weak acids with very little tendency to lose H^+ ions, so alkoxide ions are very strong bases with a *very strong* affinity for H^+. When placed in water they react immediately and completely by removing H^+ from H_2O to give the alcohol and hydroxide ion.

$$C_2H_5O^- + H_2O \xrightarrow{100\%} C_2H_5OH + OH^-$$

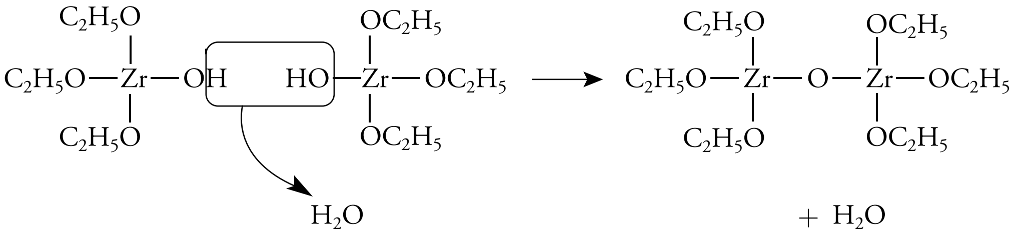
This reaction forms the basis for the start of a sequence of reactions that ultimately yields the ceramic material. Let's use zirconium(IV) ethoxide, $Zr(C_2H_5O)_4$, to illustrate the process.

■ Typical metals used in the sol-gel process are Si, Ti, Zr, Al, Sn, and Ce, all with high oxidation states.

The sequence of reactions begins with the gradual addition of water to an alcohol solution of $Zr(C_2H_5O)_4$, which causes ethoxide ions to react to form ethanol and be replaced by hydroxide ions. This reaction is called **hydrolysis** because it involves a reaction with water. The first step in the process is

$$Zr(C_2H_5O)_4 + H_2O \longrightarrow Zr(C_2H_5O)_3OH + C_2H_5OH$$

The large positive charge on the zirconium ion binds the OH^- tightly and polarizes the O—H bond, causing it to weaken. When two $Zr(C_2H_5O)_3OH$ units encounter each other they undergo an acid–base reaction. A proton is transferred from the OH attached to one zirconium ion to the OH attached to another zirconium ion. The result is the simultaneous formation of a water molecule and an oxygen bridge between the two zirconium ions.



$$\begin{array}{c} C_2H_5O \\ | \\ C_2H_5O{-}Zr{-}O\boxed{H\quad HO}{-}Zr{-}OC_2H_5 \\ | \\ C_2H_5O \end{array} \longrightarrow \begin{array}{c} C_2H_5O \qquad OC_2H_5 \\ | \qquad\qquad | \\ C_2H_5O{-}Zr{-}O{-}Zr{-}OC_2H_5 \\ | \qquad\qquad | \\ C_2H_5O \qquad OC_2H_5 \end{array} + H_2O$$

(The boxed H and HO, with OC_2H_5 above and below the second Zr, yield H_2O.)

As more and more water is added, this process continues, with ethoxide ions changing to ethanol molecules and more and more oxygen bridges being formed between zirconium ions. The result is a network of zirconium atoms bridged by oxygens, which produces extremely small insoluble particles that are essentially oxides with many residual hydroxide ions. These particles are suspended in the alcohol solvent and have a gel-like quality.[7]

---

[6] An **alkyl** group is a hydrocarbon fragment derived from an alkane by removal of a hydrogen atom. For example, the methyl group, CH_3—, is derived from methane, CH_4, and is an alkyl group. If we represent an alcohol by the general formula R—OH, where R represents an alkyl group, then the general formula of an alkoxide ion is R—O^-.

[7] The particle size is larger than one would find in a true solution, but smaller than in a typical precipitate. This type of mixture is called a *colloid*, and a colloid composed of tiny solid particles suspended in a liquid medium is called a *sol*. That's where part of the name *sol-gel* comes from.

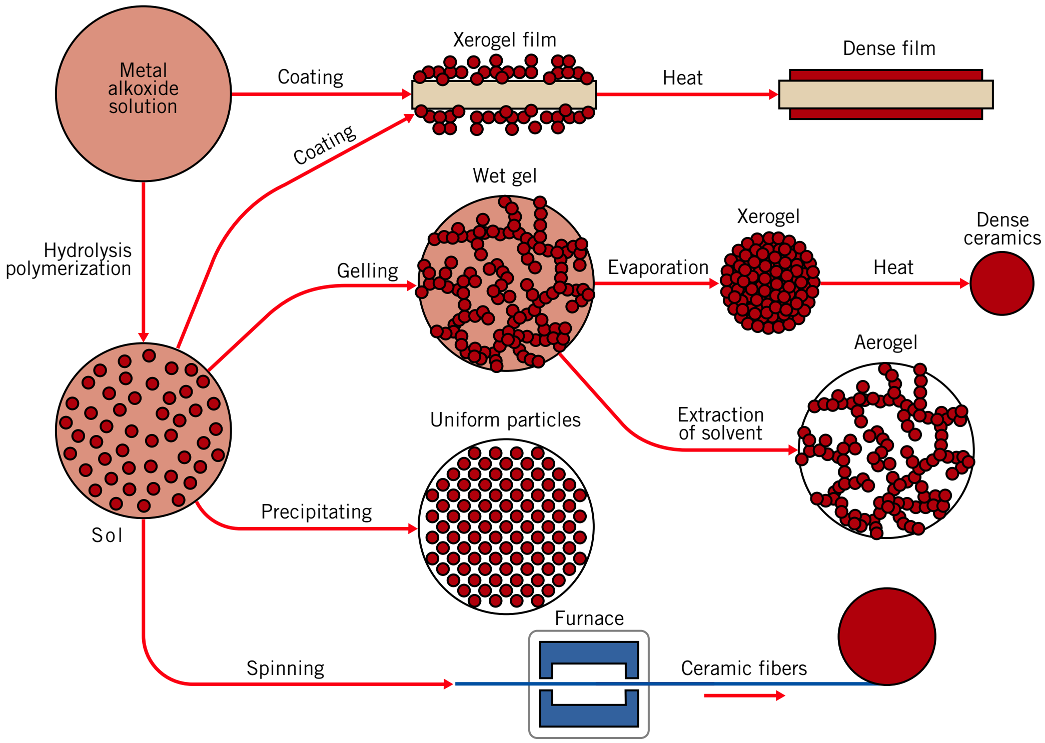


Figure 16.5 | **Sol-gel technologies and their products.**

Once the sol-gel suspension is formed, it can be used in a number of ways, as indicated in Figure 16.5. It can be deposited on a surface by dip coating to yield very thin ceramic coatings. It can be cast into a mold to produce a semisolid gelatin-like material (wet gel). The wet gel can be dried by evaporation of the solvent to give a porous solid called a **xerogel.** Further heating causes the porous structure of the xerogel to collapse and form a dense ceramic or glass with a uniform structure. If the solvent is removed from the wet gel under supercritical conditions (at a temperature above the critical temperature of the solvent), a very porous and extremely low density solid called an **aerogel** is formed (see the photo on page 61). By adjusting the viscosity of the gel suspension, ceramic fibers can be formed. And by precipitation, ultrafine and uniform ceramic powders are formed. What is amazing is that all these different forms can be made from the same material depending on how the suspension is handled.

■ Xerogels have very large internal surface areas because of their fine porous structure. Some have been found to be useful catalysts.

Summary

Brønsted–Lowry Acids and Bases. A **Brønsted–Lowry acid** (often simply referred to as a **Brønsted acid**) is a proton donor; a **Brønsted–Lowry base** (or simply **Brønsted base**) is a proton acceptor. According to the Brønsted–Lowry approach, an acid–base reaction is a proton transfer event. In an equilibrium involving a Brønsted acid and base, there are two **conjugate acid–base pairs.** The members of any given acid–base pair differ from each other by only one H^+, with the acid having one more H^+ than the base. A substance that can be either an acid or a base, depending on the nature of the other reactant, is **amphoteric** or, with emphasis on proton–transfer reactions, **amphiprotic**.

Lewis Acids and Bases. A **Lewis acid** accepts a pair of electrons from a **Lewis base** in the formation of a coordinate covalent bond. Lewis bases often have filled valence shells and must have at least one unshared electron pair. Lewis acids have an incomplete valence shell that can accept an electron pair, have double bonds that allow electron pairs to be moved to make room for an incoming electron pair from a Lewis base, or have valence shells that can accept more than an octet of electrons.

Relative Acidities and the Periodic Table. **Binary acids** contain only hydrogen and another nonmetal. Their strengths increase from top to bottom within a group and left to right across a period. **Oxoacids**, which contain oxygen atoms in addition to hydrogen and another element, increase in strength as the number of oxygen atoms on the same central atom increases. Delocalization of negative charge enhances the stability of oxoacid anions, making them weaker bases and, as a result, their conjugate acids are correspondingly stronger. Oxoacids having the same number of oxygens generally increase in strength as the central atom moves from bottom to top within a group and from left to right across a period.

Acid–Base Properties of the Elements and Their Oxides. Oxides of metals are basic anhydrides when the charge on the ion is small. Those of the Groups 1A and 2A metals neutralize acids and tend to react with water to form soluble metal hydroxides. The hydrates of metal ions tend to be proton donors when the positive charge density of the metal ion is itself sufficiently high, as it is when the ion has a 3+ charge. The small beryllium ion, Be^{2+}, forms a weakly acidic hydrated ion. Metal oxides become more acidic as the oxidation number of the metal becomes larger. Aluminum oxide is amphoteric, dissolving in both acids and bases. Chromium(VI) oxide is acidic, forming chromic acid when it dissolves in water.

Advanced Ceramics. Common ceramic materials are made from inorganic minerals obtained from the earth's crust. They are ground to fine powders, formed into shapes, and fired at high temperatures where **sintering** occurs, causing the fine particles to stick together to give a rigid solid. The **sol-gel process** uses the reaction of water with metal **alkoxides** to form extremely small, gel-like particles suspended in alcohol that can be used in a variety of ways to give coatings, **xerogels, aerogels**, fibers, and ultrafine powders for making ceramics.

Tools for Problem Solving

The following tools related to acid–base reactions were introduced in this chapter.

Brønsted–Lowry definitions (page 742)
The Brønsted–Lowry acid–base definitions, acids are proton donors and bases are proton acceptors, are useful to keep in mind whenever working with acids and bases, especially in aqueous solutions.

Conjugate acid–base pairs (page 743)
Every conjugate acid–base pair consists of an acid plus a base with less proton (H^+). You should be able to write the formula of a conjugate acid, given the formula of the base, and vice versa.

Conjugate acid–base equilibria (page 744)
The conjugate acid is always on the opposite side of an equation from its conjugate base, and the Brønsted–Lowry acid–base equilibrium is typically written with two sets of conjugate acid–base pairs.

Acid–base strength and the position of equilibrium (page 748)
If you know the relative strengths of the acids or bases in an equilibrium, you can predict the position of equilibrium. You can also use the position of equilibrium to establish the relative strengths of the acids or bases in an equilibrium.

Reciprocal relationship in acid–base strengths (page 748)
The stronger an acid, the weaker is its conjugate base. This tool can help establish the position of equilibrium when dealing with more than one acid–base pair.

Periodic trends in strengths of binary acids (page 750)
The acidities of $H{-}X$ bonds increases from left to right across a period and from top to bottom in a group. You can use the trends to predict the relative acidities of $X{-}H$ bonds, both for the binary hydrides themselves and for molecules that contain $X{-}H$ bonds.

Trends in the strengths of oxoacids (pages 750 and 753)
You use the trends to predict the relative acidities of oxoacids according to the nature of the central nonmetal as well as the number of oxygens attached to a given nonmetal. The principles involved also let you compare acidities of compounds containing different electronegative elements or electron-attracting groups bonded to an atom bonded to an —OH group.

Lewis acid–base definitions (page 755)
Keep the definitions in mind whenever analyzing an acid–base reaction in terms of Lewis acids and bases.

Acidity of metal cations (page 760)
Metal ions become better at polarizing H_2O molecules as their charge increases and their size decreases. Use this to compare the relative abilities of different metal ions to produce acidic solutions in water.

= *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com.** ILW = An Interactive Learningware solution is available for this problem. More challenging problems are marked with an asterisk *.

Review Questions

Brønsted–Lowry Acids and Bases

16.1 How is a Brønsted acid defined? How is a Brønsted base defined?

16.2 How are the formulas of the members of a conjugate acid–base pair related to each other? Within the pair, how can you tell which is the acid?

16.3 Is H_2SO_4 the conjugate acid of SO_4^{2-}? Explain your answer.

16.4 What is meant by the term *amphoteric*? Give two chemical equations that illustrate the amphoteric nature of water.

16.5 Define the term amphiprotic.

Trends in Acid–Base Strengths

16.6 Within the periodic table, how do the strengths of the binary acids vary from left to right across a period? How do they vary from top to bottom within a group?

16.7 Astatine, atomic number 85, is radioactive and does not occur in appreciable amounts in nature. On the basis of what you have learned in this chapter, answer the following.

(a) How would the acid strength of HAt compare with that of HI?

(b) How would the acid strength of $HAtO_3$ compare with that of $HBrO_3$?

16.8 Explain why nitric acid is a stronger acid than nitrous acid.

$$\underset{\text{nitric acid}}{HO{-}NO_2} \qquad \underset{\text{nitrous acid}}{HO{-}NO}$$

16.9 Explain why H_2S is a stronger acid than H_2O.

16.10 Which is the stronger Brønsted–Lowry base, $CH_3CH_2O^-$ or $CH_3CH_2S^-$? What is the basis for your selection?

16.11 Explain why $HClO_4$ is a stronger acid than H_2SeO_4.

16.12 The position of equilibrium in the equation below lies far to the left. Identify the conjugate acid–base pairs. Which of the two acids is stronger?

$$HOCl(aq) + H_2O \rightleftharpoons H_3O^+(aq) + OCl^-(aq)$$

16.13 Consider the following: CO_3^{2-} is a weaker base than hydroxide ion, and HCO_3^- is a stronger acid than water. In the equation below, would the position of equilibrium lie to the left or to the right? Justify your answer.

$$CO_3^{2-}(aq) + H_2O \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$$

16.14 Acetic acid, $HC_2H_3O_2$, is a weaker acid than nitrous acid, HNO_2. How do the strengths of the bases $C_2H_3O_2^-$ and NO_2^- compare?

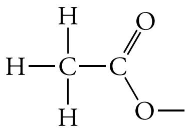
16.15 Nitric acid, HNO_3, is a very strong acid. It is 100% ionized in water. In the reaction below, would the position of equilibrium lie to the left or to the right?

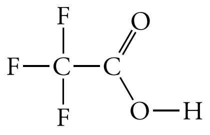
$$NO_3^-(aq) + H_2O \rightleftharpoons HNO_3(aq) + OH^-(aq)$$

16.16 $HClO_4$ is a stronger proton donor than HNO_3, but in water both acids appear to be of equal strength; they are both 100% ionized. Why is this so? What solvent property would be necessary in order to distinguish between the acidities of these two Brønsted–Lowry acids?

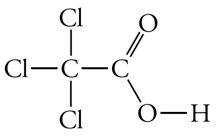
16.17 Formic acid, $HCHO_2$, and acetic acid, $HC_2H_3O_2$, are classified as weak acids, but in water $HCHO_2$ is more fully ionized than $HC_2H_3O_2$. However, if we use liquid ammonia as a solvent for these acids, they both appear to be of equal strengths; both are 100% ionized in liquid ammonia. Explain why this is so.

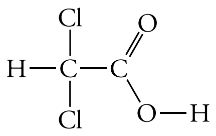
16.18 Which of the molecules below is expected to be the stronger Brønsted–Lowry acid? Why?





16.19 Which of the molecules below has the stronger conjugate base? Explain your choice.



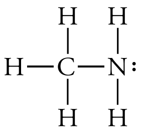


Lewis Acids and Bases

16.20 Define Lewis acid and Lewis base.

16.21 Explain why the addition of a proton to a water molecule to give H_3O^+ is a Lewis acid–base reaction.

16.22 Methylamine has the formula CH_3NH_2 and the structure



$$\begin{array}{c}\text{H}\quad\text{H}\\ \text{H—C—N:}\\ \text{H}\quad\text{H}\end{array}$$

Use Lewis structures to illustrate the reaction of methylamine with boron trifluoride.

16.23 Use Lewis structures to show the Lewis acid–base reaction between SO_3 and H_2O to give H_2SO_4. Identify the Lewis acid and the Lewis base in the reaction.

16.24 Explain why the oxide ion, O^{2-}, can function as a Lewis base but not as a Lewis acid.

16.25 The molecule SbF_5 is able to function as a Lewis acid. Explain why it is able to be a Lewis acid.

16.26 In the reaction of calcium with oxygen to form calcium oxide, each calcium gives a pair of electrons to an oxygen atom. Why isn't this viewed as a Lewis acid–base reaction?

Acid–Base Properties of the Elements and Their Oxides

16.27 Suppose that a new element was discovered. Based on the discussions in this chapter, what properties (both physical and chemical) might be used to classify the element as a metal or a nonmetal?

16.28 If the oxide of an element dissolves in water to give an acidic solution, is the element more likely to be a metal or a nonmetal?

16.29 Boric acid is very poisonous and is used in ant bait (to kill ant colonies) and to poison cockroaches. It is a weak acid with a formula often written as H_3BO_3, although it is better written as $B(OH)_3$. It functions not as a Brønsted–Lowry acid, but as a Lewis acid. Using Lewis structures, show how $B(OH)_3$ can bind to a water molecule and cause the resulting product to be a weak Brønsted acid.

16.30 Many chromium salts crystallize as hydrates containing the ion $Cr(H_2O)_6^{3+}$. Solutions of these salts tend to be acidic. Explain why.

16.31 Which ion is expected to give the more acidic solution, Fe^{2+} or Fe^{3+}? Why?

16.32 Ions of the alkali metals have little effect on the acidity of a solution. Why?

16.33 What acid is formed when the following oxides react with water?

(a) SO_3

(b) CO_2

(c) P_4O_{10}

16.34 Consider the following oxides: CrO, Cr_2O_3, CrO_3.

(a) Which is most acidic?

(b) Which is most basic?

(c) Which is most likely to be amphoteric?

16.35 Write equations for the reaction of Al_2O_3 with

(a) a strong acid, and

(b) a strong base.

Review Problems

Brønsted Acids and Bases

OH **16.36** Write the formula for the conjugate acid of each of the following.

(a) F^- **(c)** C_5H_5N **(e)** $HCrO_4^-$

(b) N_2H_4 **(d)** O_2^{2-}

16.37 Write the formula for the conjugate base of each of the following.

(a) NH_2OH **(c)** HCN **(e)** HNO_2

(b) HSO_3^- **(d)** H_5IO_6

16.38 Identify the conjugate acid–base pairs in the following reactions.

(a) $HNO_3 + N_2H_4 \rightleftharpoons NO_3^- + N_2H_5^+$

(b) $NH_3 + N_2H_5^+ \rightleftharpoons NH_4^+ + N_2H_4$

(c) $H_2PO_4^- + CO_3^{2-} \rightleftharpoons HPO_4^{2-} + HCO_3^-$

(d) $HIO_3 + HC_2O_4^- \rightleftharpoons IO_3^- + H_2C_2O_4$

16.39 Identify the conjugate acid–base pairs in the following reactions.

(a) $HSO_4^- + SO_3^{2-} \rightleftharpoons HSO_3^- + SO_4^{2-}$

(b) $S^{2-} + H_2O \rightleftharpoons HS^- + OH^-$

(c) $CN^- + H_3O^+ \rightleftharpoons HCN + H_2O$

(d) $H_2Se + H_2O \rightleftharpoons HSe^- + H_3O^+$

Trends in Acid–Base Strengths

16.40 Choose the stronger acid: **(a)** HBr or HCl; **(b)** H_2O or HF; **(c)** H_2S or HBr. Give your reasons.

16.41 Choose the stronger acid: **(a)** H_2S or H_2Se; **(b)** H_2Te or HI; **(c)** PH_3 or NH_3. Give your reasons.

16.42 Choose the stronger acid and give your reason:

(a) $HOCl$ or $HClO_2$;

(b) H_2SeO_4 or H_2SeO_3.

16.43 Choose the stronger acid: **(a)** HIO_3 or HIO_4; **(b)** H_3AsO_4 or H_3AsO_3. Give your reasons.

OH **16.44** Choose the stronger acid: **(a)** $HClO_3$ or HIO_3; **(b)** HIO_2 or $HClO_3$; **(c)** H_2SeO_3 or $HBrO_4$. Give your reasons.

16.45 Choose the stronger acid: **(a)** H_3AsO_4 or H_3PO_4; **(b)** H_2CO_3 or HNO_3; **(c)** H_2SeO_4 or $HClO_4$. Give your reasons.

Acidity of Metal Oxides and Hydrated Metal Ions

16.46 The ion $Cr(H_2O)_6^{3+}$ is weakly acidic. Write an equation showing its behavior as a Brønsted–Lowry acid in water.

16.47 The compound $Mg(OH)_2$ is basic, but $Si(OH)_4$ is an acid (silicic acid). Why?

Lewis Acids and Bases

16.48 Use Lewis symbols to diagram the reaction

$$NH_2^- + H^+ \longrightarrow NH_3$$

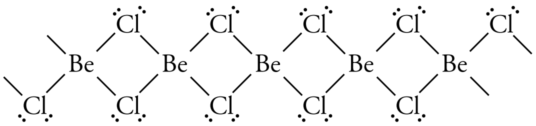
Identify the Lewis acid and Lewis base in the reaction.

16.49 Use Lewis symbols to diagram the reaction

$$BF_3 + F^- \longrightarrow BF_4^-$$

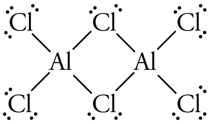
Identify the Lewis acid and Lewis base in the reaction.

16.50 Beryllium chloride, $BeCl_2$, exists in the solid as a polymer composed of long chains of $BeCl_2$ units arranged as follows.



The formula of the chain can be represented as $(BeCl_2)_n$, where n is a large number. Use Lewis structures to show how the reaction $nBeCl_2 \longrightarrow (BeCl_2)_n$ is a Lewis acid–base reaction.

16.51 Aluminum chloride, $AlCl_3$, forms molecules with itself with the formula Al_2Cl_6. Its structure is



Use Lewis structures to show how the reaction $2AlCl_3 \longrightarrow Al_2Cl_6$ is a Lewis acid–base reaction.

OH **16.52** Use Lewis structures to diagram the reaction

$$CO_2 + H_2O \longrightarrow H_2CO_3$$

Identify the Lewis acid and Lewis base in this reaction.

16.53 Use Lewis structures to diagram the reaction

$$CO_2 + O^{2-} \longrightarrow CO_3^{2-}$$

Identify the Lewis acid and Lewis base in this reaction.

16.54 Use Lewis structures to show how the following reaction can be viewed as the displacement of one Lewis base by another Lewis base from a Lewis acid. Identify the two Lewis bases and the Lewis acid.

$$NH_2^- + H_2O \longrightarrow NH_3 + OH^-$$

OH **16.55** Use Lewis structures to show how the following reaction involves the transfer of a Lewis base from one Lewis acid to another. Identify the two Lewis acids and the Lewis base.

$$CO_3^{2-} + SO_2 \longrightarrow CO_2 + SO_3^{2-}$$

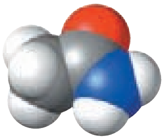
Additional Exercises

16.56 What is the formula of the conjugate acid of dimethylamine, $(CH_3)_2NH$? What is the formula of its conjugate base?

***16.57** Using liquid ammonia as a solvent, sodium amide reacts with ammonium chloride in an acid–base neutralization reaction. Assuming that these compounds are completely dissociated in liquid ammonia, write molecular, ionic, and net ionic equations for the reaction. Which substance is the acid and which is the base?

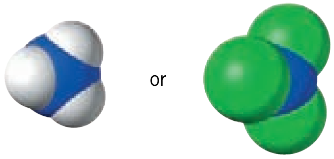
***16.58** In liquid SO_2 as a solvent, $SOCl_2$ reacts with Na_2SO_3 in a reaction that can be classified as neutralization (acid plus base yields solvent plus a salt). Write an equation for the reaction. Which solute is the acid and which is the base? Describe what is happening in terms of the Lewis definition of acids and bases.

16.59 The following space-filling model depicts the structure of a compound called ethanamide.

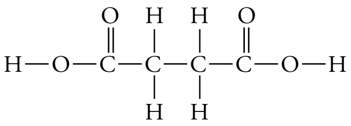


How would you expect its base strength to compare with that of ammonia? Justify your answer.

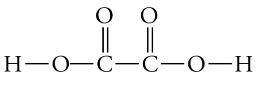
16.60 Which of the following compounds is the stronger base? Explain.



16.61 Which of the two molecules below is the stronger Brønsted–Lowry acid? Why?



$$\mathrm{H-O-\overset{\overset{\displaystyle O}{\|}}{C}-\underset{\underset{\displaystyle H}{|}}{\overset{\overset{\displaystyle H}{|}}{C}}-\underset{\underset{\displaystyle H}{|}}{\overset{\overset{\displaystyle H}{|}}{C}}-\overset{\overset{\displaystyle O}{\|}}{C}-O-H}$$



$$\mathrm{H-O-\overset{\overset{\displaystyle O}{\|}}{C}-\overset{\overset{\displaystyle O}{\|}}{C}-O-H}$$

16.62 Write equations that illustrate the amphiprotic nature of the bicarbonate ion.

16.63 Hydrogen peroxide is a stronger Brønsted–Lowry acid than water.

(a) Explain why this is so.

(b) Is an aqueous solution of hydrogen peroxide acidic or basic?

16.64 Sodium hydroxide, NaOH, is basic. Aluminum hydroxide, $Al(H_2O)_3(OH)_3$, is amphoteric. The compound O_3ClOH (usually written $HClO_4$) is acidic. Considering that each compound contains one or more OH groups, why are their acid–base properties so different?

16.65 Hydrazine, N_2H_4, is a weaker Brønsted–Lowry base than ammonia. In the following reaction, would the position of equilibrium lie to the left or to the right? Justify your answer.

$$N_2H_5^+ + NH_3 \rightleftharpoons N_2H_4 + NH_4^+$$

16.66 Identify the two Brønsted–Lowry acids and two bases in the reaction

$$NH_2OH + CH_3NH_3^+ \rightleftharpoons NH_3OH^+ + CH_3NH_2$$

16.67 In the reaction in the preceding exercise, the position of equilibrium lies to left. Identify the stronger acid in each of the conjugate pairs in the reaction.

***16.68** How would you expect the degree of ionization of $HClO_3$ to compare in the solvents $H_2O(l)$ and $HF(l)$? The reactions are

$$HClO_3 + H_2O \rightleftharpoons H_3O^+ + ClO_3^-$$
$$HClO_3 + HF \rightleftharpoons H_2F^+ + ClO_3^-$$

Justify your answer.

Multi-Concept Problems

***16.69** On the basis of the VSEPR theory, sketch the structure of the $Al(H_2O)_6^{3+}$ ion. Sketch the two possible structures of the ion formed when a proton is removed from four of the six water molecules. Which is the more likely of the two structures?

16.70 A mixture is prepared containing 0.10 *M* of each of the following: arsenic acid, sodium arsenate, arsenous acid, and sodium arsenite. What are the formulas and chemical structures of the predominant arsenic-containing species present in the solution at equilibrium? Write the equation for the equilibrium.

Exercises in Critical Thinking

16.71 Are all Arrhenius acids Brønsted–Lowry acids? Are they all Lewis acids? Give examples if they are not. Give a reasoned explanation if they are.

16.72 How could you determine whether HBr is a stronger acid than HI?

16.73 Alcohols are organic compounds that have an —OH group. Are alcohols acids or bases? Sugars have an —OH group on almost every carbon atom; are they acids or bases? Phenol is a benzene ring with an —OH group. Is phenol an acid or base?

16.74 Acid rain, acid mine runoff, and acid leaching of metals from soils are important environmental considerations. What do these topics refer to and how do they affect you as a person?

Chapters 14–16

Bringing It Together

Again we pause to provide you with an opportunity to see how well you have grasped concepts, how familiar you are with important terms, and how able you are at working chemistry problems. Keep in mind that many of the problems require tools developed in more than one chapter, including tools from Chapters 1–13. As you proceed, we encourage you to follow the approach taken by the worked examples you've studied.

1. At 25 °C and $[OH^-] = 1.00\ M$, the reaction

$$I^-(aq) + OCl^-(aq) \longrightarrow OI^-(aq) + Cl^-(aq)$$

has the rate law: rate $= (0.60\ \text{L mol}^{-1}\ \text{s}^{-1})[I^-][OCl^-]$. Calculate the rates of the reaction when $[OH^-] = 1.00\ M$ in solutions with the following compositions:

(a) 0.74 g KI dissolved in 475 mL of a solution that contains $0.0200\ M\ OCl^-$.

(b) $[I^-] = 0.100\ M$ and $[OCl^-] = 0.0400\ M$.

2. A reaction has the stoichiometry: $3A + B \longrightarrow C + D$. The following data were obtained for the initial rate of formation of *C* at various concentrations of *A* and *B*.

Initial Concentrations		Initial Rate of Formation of *C* (mol L^{-1} s^{-1})
[*A*]	**[*B*]**	
0.010	0.010	2.0×10^{-4}
0.020	0.010	8.0×10^{-4}
0.020	0.033	2.64×10^{-3}

(a) What is the rate law for the reaction?

(b) What is the value of the rate constant?

(c) What is the rate at which *C* is formed if $[A] = 0.017\ M$ and $[B] = 0.033\ M$?

3. If the concentration of a particular reactant is doubled and the rate of the reaction is cut in half, what must be the order of the reaction with respect to that reactant?

4. Organic compounds that contain large proportions of nitrogen and oxygen tend to be unstable and are easily decomposed. Hexanitroethane, $C_2(NO_2)_6$, decomposes according to the equation

$$C_2(NO_2)_6 \longrightarrow 2NO_2 + 4NO + 2CO_2$$

The reaction in CCl_4 as a solvent is first-order with respect to $C_2(NO_2)_6$. At 70.0 °C, $k = 2.41 \times 10^{-6}\ \text{s}^{-1}$ and at 100.0 °C $k = 2.22 \times 10^{-4}\ \text{s}^{-1}$.

(a) What is the half-life of $C_2(NO_2)_6$ at 70.0 °C? What is the half-life at 100.0 °C?

(b) If 2.24 g of $C_2(NO_2)_6$ is dissolved in CCl_4 at 70.0 °C to give 125 mL of solution, what will be the $C_2(NO_2)_6$ concentration after 525 minutes?

(c) What is the value of the activation energy of this reaction, expressed in kilojoules?

(d) What is the reaction's rate constant at 120.0 °C?

(e) Draw a reasonable Lewis structure for $C_2(NO_2)_6$.

5. Radioactive strontium-90, ^{90}Sr, has a half-life of 28 years.

(a) What fraction of a sample of ^{90}Sr will remain after three half-lives?

(b) What fraction of a sample of ^{90}Sr will remain after 168 years?

(c) If the amount of ^{90}Sr remaining in a sample is only one-sixteenth of the amount originally present, how many years has the sample been undergoing radioactive decay?

(d) If the amount of ^{90}Sr remaining in a sample is only one-sixth of the amount originally present, how many years has the sample been undergoing radioactive decay?

6. The reaction $2A + 2B \longrightarrow M + N$ has the rate law: rate $= k[A]^2$. At 25 °C, $k = 1.0 \times 10^{-4}\ \text{L mol}^{-1}\ \text{s}^{-1}$. If the initial concentrations of *A* and *B* are 0.250 *M* and 0.150 *M*, respectively.

(a) What is the half-life of the reaction?

(b) What will be the concentrations of *A* and *B* after 30.0 minutes?

7. The decomposition of ozone, O_3, is believed to occur by the two-step mechanism

$$\begin{array}{ll} O_3 \longrightarrow O_2 + O & \text{(slow)} \\ O + O_3 \longrightarrow 2O_2 & \text{(fast)} \\ \hline 2O_3 \longrightarrow 3O_2 & \text{(net reaction)} \end{array}$$

If this is the mechanism, what is the reaction's rate law?

8. One possible mechanism for the decomposition of ethane, C_2H_6, into ethylene, C_2H_4, and hydrogen,

$$C_2H_6 \longrightarrow C_2H_4 + H_2$$

includes the following steps.

(1) $C_2H_6 \longrightarrow 2CH_3\cdot$
(2) $CH_3\cdot + C_2H_6 \longrightarrow CH_4 + C_2H_5\cdot$
(3) $C_2H_5\cdot \longrightarrow C_2H_4 + H\cdot$
(4) $H\cdot + C_2H_6 \longrightarrow C_2H_5\cdot + H_2$
(5) $H\cdot + C_2H_5\cdot \longrightarrow C_2H_6$

(a) Which steps initiate the reaction?

(b) Which are propagation steps?

(c) Which is a termination step?

9. Write the appropriate mass-action expression, using molar concentrations, for these reactions.

(a) $NO_2(g) + N_2O(g) \rightleftharpoons 3NO(g)$

(b) $CaSO_3(s) \rightleftharpoons CaO(s) + SO_2(g)$

(c) $NiCO_3(s) \rightleftharpoons Ni^{2+}(aq) + CO_3^{2-}(aq)$

10. At a certain temperature, the reaction $2HF(g) \rightleftharpoons H_2(g) + F_2(g)$ has $K_c = 1.2 \times 10^{-13}$. Does this reaction proceed far toward completion when equilibrium is reached? If 0.010 mol HF was placed in a 1.00 L container and the system was permitted to come to equilibrium, what would be the concentrations of H_2 and F_2 in the container?

11. Suppose a mixture was prepared containing 0.0100 mol H_2, 0.0150 mol F_2, and 0.0180 mol HF in a 1.25 L reaction vessel. What will the concentrations of all the gases be when equilibrium is reached? The reaction is $2HF(g) \rightleftharpoons H_2(g) + F_2(g)$ for which the equilibrium constant $K_c = 1.2 \times 10^{-13}$.

12. At 100.0 °C, the reaction $2NO_2(g) \rightleftharpoons N_2O_4(g)$ has $K_P = 6.5 \times 10^{-2}$. What is the value of K_c at this temperature?

13. At 1000 °C, the reaction $NO_2(g) + SO_2(g) \rightleftharpoons NO(g) + SO_3(g)$ has $K_c = 3.60$. If 0.100 mol NO_2 and 0.100 mol SO_2 are placed in a 5.00 L container and allowed to react, what will all the concentrations be when equilibrium is reached? What will the new equilibrium concentrations be if 0.010 mol NO and 0.010 mol SO_3 are added to this original equilibrium mixture?

14. At a certain temperature, $K_c = 0.450$ for the reaction

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$$

Suppose 7.0 g PCl_3 and 4.50 g Cl_2 are placed in a 12.0 L reaction vessel and allowed to come to equilibrium. How much heat in kilojoules will be absorbed or evolved by the time equilibrium has been reached? (Assume ΔH is effectively independent of temperature.)

15. For the reaction in the preceding question, $\Delta H° = -41.8$ kJ. How will the equilibrium concentration of NO be affected if:

(a) More NO_2 is added to the container?

(b) Some SO_3 is removed from the container?

(c) The temperature of the reaction mixture is raised?

(d) Some SO_2 is removed from the mixture?

(e) The pressure of the gas mixture is lowered by expanding the volume to 10.0 L?

16. At 100 °C, the reaction $2NO_2(g) \rightleftharpoons N_2O_4(g)$ has $K_P = 6.5 \times 10^{-2}$. Suppose a mixture of these gases was prepared at 100 °C in a 400 mL vessel with the following partial pressures: $P_{NO_2} = 0.348$ atm and $P_{N_2O_4} = 0.678$ atm. What will the partial pressures of the gases be at equilibrium? What will the total pressure of the gas mixture be? What is the total mass of gas in the reaction vessel?

17. Which is the stronger acid, H_3PO_3 or H_3PO_4? Justify your answer.

18. Which is the stronger acid, H_2S or H_2Te?

19. What are the conjugate acids of (a) HSO_3^-, (b) N_2H_4?

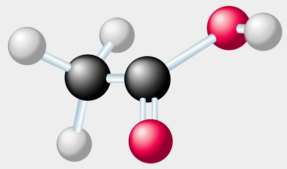
20. What are the conjugate bases of (a) HSO_3^-, (b) N_2H_4, (c) $C_5H_5NH^+$?

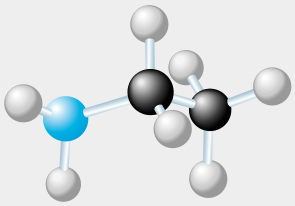
21. Identify the conjugate acid-base pairs in the reaction

$$CH_3NH_2 + NH_4^+ \rightleftharpoons CH_3NH_3^+ + NH_3$$

22. Methylamine, CH_3NH_2, is a weak base. Write the chemical equation for the equilibrium that occurs in an aqueous solution of this solute. Identify the two acids and two bases in the system.

23. Suppose the following two pure substances are mixed. Write the formulas of the ions that form. Which of the reactants is an acid and which is a base? Which of the ions that form is an acid and which is a base? Write the chemical equation for the reaction.



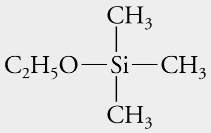


24. Use Lewis structures to diagram the reaction between the Lewis base OH^- and the Lewis acid SO_3.

25. *X*, *Y*, and *Z* are all nonmetallic elements in the same period of the periodic table where they occur, left to right, in the order given. Which would be a stronger binary acid than the binary acid of *Y*: the binary acid of *X* or the binary acid of *Z*? Explain.

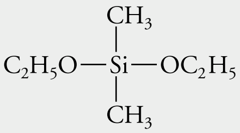
26. Is the compound $Sb(OH)_5$ likely to be acidic, basic, or neutral in water? Justify your answer.

27. Consider the two compounds shown below.



$$C_2H_5O-\overset{\displaystyle CH_3}{\underset{\displaystyle CH_3}{Si}}-CH_3$$

(1)



$$C_2H_5O-\overset{\displaystyle CH_3}{\underset{\displaystyle CH_3}{Si}}-OC_2H_5$$

(2)

(a) Suppose water were added gradually to an ethanol solution of compound (1). Draw the Lewis structure of the product that would form.

(b) Use Lewis structures to describe the product that would form if an excess of water were added to an ethanol solution of compound (2).

28. If sodium metal is added to pure ethanol, the following reaction takes place in which sodium ethoxide (containing the strong Brønsted–Lowry base $C_2H_5O^-$) is formed.

$$2Na + 2C_2H_5OH \longrightarrow 2NaC_2H_5O + H_2(g)$$

Is this an acid base reaction? Explain.

29. The acetate ion is a weak Brønsted–Lowry base. Write a chemical equation that shows why an aqueous solution of sodium acetate is slightly basic.

17 Acid–Base Equilibria in Aqueous Solutions

17.4 | Determining K_a and K_b Values

17.5 | pH of Weak Acid and Weak Base Solutions

17.6 | pH of Salt Solutions

17.7 | Buffer Solutions

17.8 | Polyprotic Acids

17.9 | Acid–Base Titrations

This olympic weightlifter is using large amounts of energy to try to lift the heaviest weight in his event. Inside his body there are literally thousands of chemical reactions happen simultaneously in support of his effort. Some chemical reactions happen spontaneously without conscious thought. Other chemical reactions, such as those that cause muscle movement, occur in response to signals from the brain. Many of these reactions produce or consume acids and bases. The pain that the weightlifter will feel after his event may be from the buildup of lactic acid that occurs during strenuous exercise. Carbon dioxide, transported as the bicarbonate ion in the body, is another product of metabolism. Understanding how the body manages its acid–base balance starts with the fundamentals of acid–base equilibria. © AP/Wide World Photos.

This Chapter in Context

In Chapters 15 and 16 we discussed the general principles of chemical equilibrium and our concepts about the chemical properties of acids and bases. Using the principles from Chapter 10 about molecular polarity and the concept of delocalization of electrons, we were able to qualitatively compare the strengths of acids and bases. Our goal in this chapter is to bring these concepts together as we examine the quantitative aspects of acid–base chemistry. In particular we are interested in acids, bases, and their mixtures as they affect the concentration of hydronium ions in solution. As we do this, the concept of pH will be developed and used.

The principles we develop here have applications not only in traditional chemistry labs, but also in labs that investigate environmental, forensic, and biochemical problems. High-tech laboratories interested in materials science and nanotechnology often use the principles of acid–base equilibria. The consumer-oriented industries that make products such as cosmetics, foods, beverages, and cleaning chemicals all employ chemists who know that control of pH is very important in safe and effective consumer products.

17.1 | Water, pH, and "p" Notation

There are literally thousands of weak acids and bases, and their strengths vary widely. Both the acetic acid in vinegar and the carbonic acid in pressurized soda water, for example, are classified as weak. Yet carbonic acid is only about 3% as strong an acid as acetic acid. To study such differences quantitatively, we need to explore acid–base equilibria in greater depth. This requires that we first discuss a particularly important equilibrium that exists in *all* aqueous solutions—namely, the ionization of water itself.

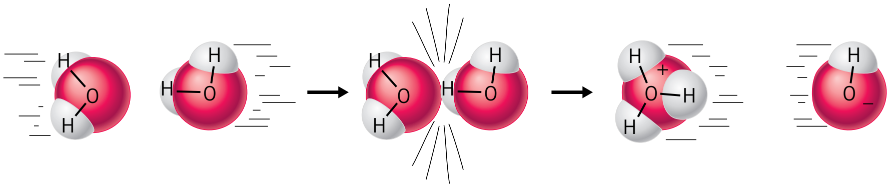
Autoionization of Water

Using sensitive instruments, pure water is observed to weakly conduct electricity, indicating the presence of very small concentrations of ions. They arise from the very slight self-ionization, or *autoionization,* of water itself, represented by the following equilibrium equation.

■ We've omitted the usual (*aq*) following the symbols for ions in water for the sake of simplicity.

$$H_2O + H_2O \rightleftharpoons H_3O^+ + OH^-$$

The forward reaction requires a collision of two H_2O molecules.



Its equilibrium law, following the procedures developed in Chapter 15 (i.e., we leave pure liquids, such as water in this case, out of the equilibrium law, see page 707), is

TOOLS

Ion product constant of water, K_w

$$[H_3O^+]\,[OH^-] = K_w \qquad (17.1)$$

Since water is a pure liquid, with a constant 55.6 molar concentration, it does not appear in this equilibrium law. Because of the importance of the autoionization equilibrium, its equilibrium constant is given the special symbol, $\boldsymbol{K_w}$, that is called the **ion product constant of water.**

Often, for convenience, we omit the water molecule that carries the hydrogen ion and write H^+ in place of H_3O^+. The equilibrium equation for the autoionization of water then simplifies to

$$H_2O \rightleftharpoons H^+ + OH^-$$

The equation for K_w based on this is likewise simplified.

$$\boxed{[H^+]\,[OH^-] = K_w} \tag{17.2}$$

In pure water, the concentrations of H^+ and OH^- produced by the autoionization are equal because the ions are formed in equal numbers. It's been found that the concentrations have the following values at 25 °C.

$$[H^+] = [OH^-] = 1.0 \times 10^{-7} \text{ mol L}^{-1}$$

Therefore, at 25 °C,

$$K_w = (1.0 \times 10^{-7}) \times (1.0 \times 10^{-7})$$

$$K_w = 1.0 \times 10^{-14} \tag{17.3}$$

As with other equilibrium constants, the value of K_w varies with temperature (see Table 17.1). Unless stated otherwise we will deal with systems at 25 °C.

Table 17.1 K_w at Various Temperatures

Temperature (°C)	K_w
0	1.5×10^{-15}
10	3.0×10^{-15}

[a] Normal body temperature

Effect of Solutes on $[H^+]$ and $[OH^-]$

Water's autoionization takes place in *any* aqueous solution, and because of the effects of other solutes, the molar concentrations of H^+ and OH^- may not be equal. Nevertheless, their product, K_w, is the same. Thus, although Equations 17.1–17.3 were derived for pure water, they also apply to dilute aqueous solutions. The significance of this must be emphasized. *In any aqueous solution, the product of* $[H^+]$ *and* $[OH^-]$ *equals* K_w*, although the two molar concentrations may not actually equal each other.*

Criteria for Acidic, Basic, and Neutral Solutions

One of the consequences of the autoionization of water is that *in any aqueous solution, there are always both* H_3O^+ *and* OH^- *ions, regardless of what solutes are present.* This means that in a solution of the acid HCl there is some OH^-, and in a solution of the base NaOH, there is some H_3O^+. We call a solution acidic or basic depending on which ion has the largest concentration.

A *neutral solution* is one in which the molar concentrations of H_3O^+ and OH^- are equal. An *acidic solution* is one in which some solute has made the molar concentration of H_3O^+ greater than that of OH^-. On the other hand, a *basic solution* exists when the molar concentration of OH^- exceeds that of H_3O^+.

Neutral solution $[H_3O^+] = [OH^-]$
Acidic solution $[H_3O^+] > [OH^-]$
Basic solution $[H_3O^+] < [OH^-]$

■ Because of the autoionization of water, even the most acidic solution has some OH^-, and even the most basic solution has some H_3O^+.

If we consider the autoionization constant of water, we can look at some quantitative relationships of acids and bases. For instance, we can take a solution that has an easily measurable 0.0020 *M* concentration of H_3O^+ and calculate an extremely small OH^- concentration that exists in the same solution. Rearranging Equation 17.3, we get

$$[OH^-] = \frac{K_w}{[H_3O^+]} = \frac{1.0 \times 10^{-14}}{2.0 \times 10^{-3}} = 5.0 \times 10^{-12}\ M$$

A similar calculation allows us to determine the hydronium ion concentration if we know the hydroxide ion concentration.

Practice Exercises

17.1 | Commercial, concentrated, hydrochloric acid has a concentration of 12 moles per liter. If the molarity of hydronium ions is assumed to also be 12 *M*, what is the concentration of hydroxide ions? (*Hint:* Use the relationships just discussed.)

17.2 | An aqueous solution of sodium bicarbonate, $NaHCO_3$, has a molar concentration of hydroxide ion of 7.8×10^{-6} *M*. What is the molar concentration of hydrogen ion? Is the solution acidic, basic, or neutral?

The pH Concept

In most solutions of weak acids and bases, the molar concentrations of H^+ and OH^- are very small, like those we just discussed. Writing and comparing two exponential values is not always easy. A Danish chemist, S. P. L. Sørenson (1868–1939), suggested an easier approach.

To make comparisons of small values of $[H^+]$ easier, Sørenson defined a quantity that he called the **pH** of the solution as follows.

Definition of pH

$$\text{pH} = -\log [H^+] \tag{17.4}$$[1]

The properties of logarithms let us rearrange Equation 17.4 as follows.

$$[H^+] = 10^{-\text{pH}} \tag{17.5}$$

Equation 17.4 can be used to calculate the pH of a solution if its molar concentration of H^+ is known. On the other hand, if the pH is known and we wish to calculate the molar concentration of hydrogen ions, we apply Equation 17.5. For example, if the hydrogen ion concentration, $[H^+]$, is 3.6×10^{-4}, we take the logarithm of this value (which is -3.44) and change its sign so that the result is a pH of 3.44. With digital calculators, it's as simple as pressing the log key and *then* changing the sign. Determining the hydrogen ion concentration using Equation 17.5 requires that we change the sign of the pH and then take the antilogarithm. For instance, if we are given a pH of 12.58 we first change it to -12.58. We then take the antilogarithm according to the instructions that came with your calculator. In this case the result is $2.6 \times 10^{-13} = [H^+]$.

■ **Calculating pH**

$$\begin{aligned} \text{pH} &= -\log [H^+] \\ &= -\log (3.6 \times 10^{-4}) \\ &= -(-3.44) \\ &= 3.44 \end{aligned}$$

Calculating $[H^+]$

$$\begin{aligned} -\log [H^+] &= \text{pH} \\ -\log [H^+] &= 12.58 \\ \log [H^+] &= -12.58 \\ [H^+] &= \text{antilog } (-12.58) \\ [H^+] &= 10^{-12.58} \\ [H^+] &= 2.6 \times 10^{-13}\ M \end{aligned}$$

■ If you still have questions about these calculations, see the mathematics review in Appendix A.

Acidic, Basic, and Neutral Solutions

One meaning attached to pH is that it is a measure of the acidity of a solution. Hence, we may define *acidic*, *basic*, and *neutral* in terms of pH values. At 25 °C, in pure water, or in any solution that is *neutral*,

$$[H^+] = [OH^-] = 1.0 \times 10^{-7}\ M$$

Therefore, by Equation 17.4, *the pH of a neutral solution at 25 °C is 7.00.*[2]

An *acidic solution* is one in which $[H^+]$ is larger than 10^{-7} *M* and so has a pH *less* than 7.00. Thus, *as a solution's acidity increases, its pH decreases.*

A *basic solution* is one in which the value of $[H^+]$ is less than 10^{-7} *M* and so has a pH that is *greater* than 7.00. *As a solution's acidity decreases, its pH increases.* These simple relationships may be summarized as follows. At 25 °C:

$\text{pH} = 7.00$	**Neutral solution**
$\text{pH} < 7.00$	**Acidic solution**
$\text{pH} > 7.00$	**Basic solution**

The pH values for some common substances are given on a pH scale in Figure 17.1.

■ Neutral pH is 7.00 only for 25 °C. At other temperatures a neutral solution still has $[H^+] = [OH^-]$, but because K_w changes with temperature, so do the values of $[H^+]$ and $[OH^-]$. This causes the pH of the neutral solution to differ from 7.00. For example, at normal body temperature (37 °C), a neutral solution has $[H^+] = [OH^-] = 1.6 \times 10^{-7}$, so the pH = 6.80.

---

[1] In this equation and similar ones, like Equation 17.6, the logarithm of only the numerical part of the bracketed term is taken. The physical units must be mol L^{-1}, but they are set aside for the calculation.

[2] Recall that the rule for significant figures in logarithms is that *the number of decimal places in the logarithm of a number equals the number of significant figures in the number.* For example, 3.2×10^{-5} has just two significant figures. The logarithm of this number, displayed on a pocket calculator, is -4.494850022. We write the logarithm, when correctly rounded, as -4.49.

One of the deceptive features of pH is how much the hydrogen ion concentration changes with a relatively small change in pH. Thus, because of the logarithmic scale, a change of one pH unit corresponds to a ten-fold change in the hydrogen ion concentration. For example, at pH 6 the hydrogen ion concentration is 1×10^{-6} mol L^{-1}. At pH 5, it's 1×10^{-5} mol L^{-1}, or ten times greater. That's a major difference.

Solutions having hydrogen ion concentrations greater than 1 *M* can be prepared and they should have negative pH values. However, at such high concentrations it is usually easier to simply write the molarity of the hydrogen ions. For example, in a solution where the value of $[H^+]$ is 2 *M*, the "2" is a simple enough number; we can't simplify it further by using its corresponding pH value. When $[H^+]$ is 2.00 *M*, the pH, calculated by Equation 17.4, would be $-\log(2.00)$ or -0.301. There is nothing wrong with negative pH values, but they offer no advantage over just writing the actual value of $[H^+]$.

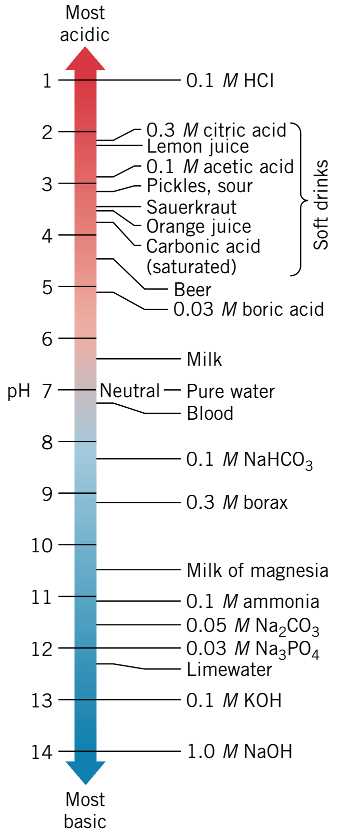

Figure 17.1 | **The pH scale.** Common substances and their approximate pH values.

"p" Notation

The logarithmic definition of pH, Equation 17.4, has proved to be so useful that it has been adapted to quantities other than $[H^+]$. Thus, for any quantity *X*, we may define a term, p*X*, in the following way.

$$pX = -\log X \tag{17.6}$$

Defining the p-function, p*X*

For example, to express small concentrations of hydroxide ion, we can define the **pOH** of a solution as

$$\text{pOH} = -\log[\text{OH}^-]$$

Similarly, for K_w we can define $\mathbf{p}K_w$ as follows.

$$pK_w = -\log K_w$$

The numerical value of pK_w at 25 °C equals $-\log(1.0 \times 10^{-14})$ or $-(-14.00)$. Thus,

$$pK_w = 14.00 \text{ (at 25 °C)}$$

A useful relationship among pH, pOH, and pK_w can be derived by taking the logarithm of all terms in Equation 17.1 or 17.2 and changing the sign to obtain Equation 17.7:

$$\text{pH} + \text{pOH} = pK_w = 14.00 \qquad \text{(at 25 °C)} \tag{17.7}$$

Relating pH and pOH to pK_w

This tells us that in an aqueous solution of any solute at 25 °C, the sum of pH and pOH is 14.00.

pH Calculations

Let's now look at some pH calculations using Equations 17.4 and 17.7. These are calculations you will be performing often in the rest of this chapter.

If we know the $[H^+]$ of a solution—let's use 6.3×10^{-5} *M* as an example—we can calculate the pH by taking the logarithm and changing the sign. The pH we calculate should be 4.20. We now have two ways to determine the pOH. Using Equation 17.2 allows us to determine $[OH^-]$, and then we can take the logarithm and change the sign to calculate the pOH. An easier method is to use Equation 17.7 and simply subtract the pH from 14.00. This subtraction tells us that the pOH must be 9.80. Equations 17.4 and 17.7 tell us that if we know one of the four terms, $[H^+]$, $[OH^-]$, pH, or pOH, we can calculate the other three. Another way to look at this helps us with solving a problem. If we are given any one of these four values, it is the same as knowing all of them. For instance, if you know the pOH but a problem requires the $[H^+]$, we know how to easily calculate the needed value. The following practice exercises make use of these calculations.

■ **Calculating pH and pOH**

$$\begin{aligned} \text{pH} &= -\log(6.3 \times 10^{-5}) \\ &= -(-4.20) \\ &= 4.20 \\ pK_w &= 14.00 = 4.20 + \text{pOH} \\ \text{pOH} &= 14.00 - 4.20 \\ &= 9.80 \end{aligned}$$

Practice Exercises

17.3 | Water draining from old coal and mineral mines often has pH values of 4.0 or lower. The cause is thought to stem from reactions of ground water and oxygen with iron pyrite, FeS. What are the pOH, $[H^+]$, and $[OH^-]$ in an acid mine drainage sample that has a pH of 4.25? (*Hint:* Recall that pH, pOH, $[H^+]$, and $[OH^-]$ are all interrelated using the K_w and pK_w.)

17.4 | Because rain washes pollutants out of the air, the lakes in many parts of the world have undergone pH changes. In a New England state, the water in one lake was found to have a hydrogen ion concentration of 3.2×10^{-5} mol L^{-1}. What are the calculated pH and pOH values of the lake's water? Is the water acidic or basic?

17.5 | Find the values of $[H^+]$ and $[OH^-]$ that correspond to each of the following values of pH. State whether each solution is acidic or basic.

(a) 2.90 (the approximate pH of lemon juice)
(b) 3.85 (the approximate pH of sauerkraut)
(c) 10.81 (the pH of milk of magnesia, an antacid)
(d) 4.11 (the pH of orange juice, on the average)
(e) 11.61 (the pH of dilute, household ammonia)

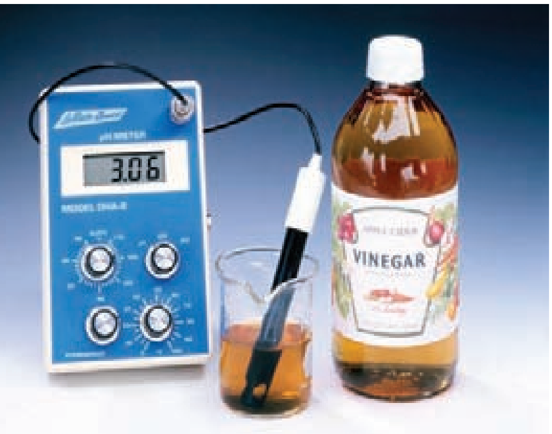

Figure 17.2 | **A pH meter.** After the instrument has been calibrated with a solution of a known pH, the combination electrode is dipped into the solution to be tested and the pH is read from the meter. *(Richard Megna/ Fundamental Photographs.)*

pH Meters

One of the remarkable things about pH is that it can be easily measured using an instrument called a pH meter (Figure 17.2). An electrode system sensitive to the hydrogen ion concentration in a solution is first dipped into a standard solution of known pH to calibrate the instrument. Once calibrated, the apparatus can then be used to measure the pH of any other solution simply by immersing the electrodes into it. The accuracy of pH meter measurements is usually ± 0.02 pH units.

17.2 | pH of Strong Acid and Base Solutions

Many solutes affect the pH of an aqueous solution. In this section we examine how strong acids and bases behave and how to calculate the pH of their solutions. Weak acids and bases have similar effects, which we will discuss in the next section.

Strong Acids and Bases

In Section 16.3 we saw that strong acids and bases are considered to be 100% dissociated in an aqueous solution. This makes calculating the concentrations of H^+ and OH^- in their solutions a relatively simple task.

■ If necessary, review the list of strong acids on page 170.

When the solute is a strong monoprotic acid, such as HCl or HNO_3, the molarity of H^+ will be the same as the molarity of the strong acid. Thus, a 0.010 *M* solution of HCl contains 0.010 mol L^{-1} of H^+ and a 0.0020 *M* solution of HNO_3 contains 0.0020 mol L^{-1} of H^+.

To calculate the pH of a solution of a strong monoprotic acid, we use the molarity of the H^+ obtained from the stated molar concentration of the acid. Thus, the 0.010 *M* HCl solution mentioned above has a pH of 2.00.

For strong bases, calculating the OH^- concentration is similarly straightforward. A 0.050 *M* solution of NaOH contains 0.050 mol L^{-1} of OH^- because the base is fully dissociated and each mole of NaOH releases one mole of OH^- when it dissociates. For bases such as $Ba(OH)_2$ we have to recognize that two moles of OH^- are released by each mole of the base.

$$Ba(OH)_2(s) \longrightarrow Ba^{2+}(aq) + 2OH^-(aq)$$

Therefore, if a solution contained 0.010 mol $Ba(OH)_2$ per liter, the concentration of OH^- would be 0.020 *M*. Of course, once we know the OH^- concentration we can calculate pOH, from which we can calculate the pH. Working through the following practice exercises will help to solidify these methods.

Practice Exercises

17.6 | Calculate the $[H^+]$, pH, and pOH in 0.0050 *M* HNO_3. (*Hint:* HNO_3 is a strong acid.)

17.7 | Calculate the pOH, $[H^+]$, and pH in a solution made by weighing 1.20 g of KOH and dissolving it in sufficient water to make 250.0 mL of solution.

17.8 | Rhododendrons are shrubs that produce beautiful flowers in the springtime. They only grow well in soil that has a pH that is 5.5 or slightly lower. What is the hydrogen ion concentration in the soil moisture if the pH is 5.5?

Effect of Solute on the Ionization of Water

In the preceding calculations, we have made a critical and correct assumption—namely, that the autoionization of water contributes negligibly to the total $[H^+]$ in a solution of an acid and to the total $[OH^-]$ in a solution of a base.[3] Let's take a closer look at this.

In a solution of an acid, there are actually *two* sources of H^+. One is from the ionization of the acid itself and the other is from the autoionization of water. Thus,

$$[H^+]_{\text{total}} = [H^+]_{\text{from solute}} + [H^+]_{\text{from } H_2O}$$

■ A similar equation applies to the equilibrium OH^- concentration in a solution of a base.

$$[OH^-]_{\text{equilib}} = [OH^-]_{\text{from solute}} + [OH^-]_{\text{from } H_2O}$$

Except in very dilute solutions of acids, the amount of H^+ contributed by the water ($[H^+]_{\text{from } H_2O}$) is small compared to the amount of H^+ contributed by the acid ($[H^+]_{\text{from solute}}$). For instance, in 0.020 *M* HCl the molarity of OH^- is 5.0×10^{-13} *M*. The only source of OH^- in this acidic solution is from the autoionization of water, and the amounts of OH^- and H^+ *formed by the autoionization of water* must be equal. Therefore, $[H^+]_{\text{from } H_2O}$ also equals 5.0×10^{-13} *M*. If we now look at the total $[H^+]$ for this solution, we have

$$[H^+]_{\text{total}} = \underset{\text{(from HCl)}}{0.020\ M} + \underset{\text{(from } H_2O)}{5.0 \times 10^{-13}\ M}$$

$$= 0.020\ M \text{ (rounded correctly)}$$

In any solution of an acid, the autoionization of water is suppressed by the H^+ furnished by the solute. It's simply an example of Le Châtelier's principle. If we look at the autoionization reaction, we can see that if some H^+ is provided by an external source (an acidic solute, for example), the position of equilibrium will be shifted to the left.

$$H_2O \rightleftharpoons H^+ + OH^-$$

Adding H^+ from a solute causes the position of equilibrium to shift to the left.

As the results of our calculation have shown, the concentrations of H^+ and OH^- *from the autoionization reaction* are reduced well below their values in a neutral solution (1.0×10^{-7} *M*). Therefore, except for *very* dilute solutions (10^{-6} *M* or less), we will assume that all of the H^+ in the solution of an acid comes from the solute. Similarly, *we'll assume that in a solution of a base, all the* OH^- *comes from the dissociation of the solute.*

---

[3] The autoionization of water cannot be neglected when working with very dilute solutions of acids and bases.

17.3 | Ionization Constants, K_a and K_b

As you've learned in Chapter 16, weak acids and bases are incompletely ionized in water and exist in solution as molecules that are in equilibria with the ions formed by their reactions with water. To deal quantitatively with these equilibria it is essential that you be able to write correct chemical equations for the equilibrium reactions, from which you can then obtain the corresponding correct equilibrium laws. Fortunately, there is a pattern that applies to the way these substances react. *Once you've learned how to write the correct equation for one acid or base, you can write the correct equation for any other.*

Reaction of a Weak Acid with Water

In aqueous solutions, all weak acids behave the same way. They are Brønsted acids and, therefore, proton donors. Some examples are $HC_2H_3O_2$, HSO_4^-, and NH_4^+. In water, these participate in the following equilibria.

$$HC_2H_3O_2 + H_2O \rightleftharpoons H_3O^+ + C_2H_3O_2^-$$

$$HSO_4^- + H_2O \rightleftharpoons H_3O^+ + SO_4^{2-}$$

$$NH_4^+ + H_2O \rightleftharpoons H_3O^+ + NH_3$$

Notice that in each case, the acid reacts with water to give H_3O^+ and the corresponding conjugate base. We can represent these reactions in a general way using HA to represent the formula of the weak acid and A^- to represent the anion.

TOOLS

General equation for the ionization of a weak acid

$$HA + H_2O \rightleftharpoons H_3O^+ + A^- \qquad \textbf{(17.8)}$$

As you can see from the equations above, HA does not have to be electrically neutral; it can be a molecule such as $HC_2H_3O_2$, a negative ion such as HSO_4^- or a positive ion such as NH_4^+. (Of course, the actual charge on the conjugate base will then depend on the charge on the parent acid.)

Following the procedure developed in Chapter 15, we can also write a general equation for the equilibrium law, omitting the concentration of liquid water as usual, for Equation 17.8,

■ Some call K_a the ***acid dissociation constant.***

$$\frac{[H_3O^+][A^-]}{[HA]} = K_a \qquad \textbf{(17.9)}$$

The new constant $\boldsymbol{K_a}$ is called an **acid ionization constant**. Abbreviating H_3O^+ as H^+, the equation for the ionization of the acid can be simplified as

$$HA \rightleftharpoons H^+ + A^-$$

from which the expression for K_a is obtained directly.

$$K_a = \frac{[H^+][A^-]}{[HA]} \qquad \textbf{(17.10)}$$

You should learn how to write the chemical equation for the ionization of a weak acid and be able to write the equilibrium law corresponding to its K_a. For example, if we have a weak acid such as HNO_2 we can write the ionization reaction as

$$HNO_2 \rightleftharpoons H^+ + NO_2^-$$

and the corresponding equilibrium law is

$$K_a = \frac{[H^+][NO_2^-]}{[HNO_2]}$$

Practice Exercises

17.9 | For each of the following acids, write the equation for its ionization in water and the appropriate expression for K_a: (a) $HC_2H_3O_2$, (b) $(CH_3)_3NH^+$, (c) H_3PO_4. (*Hint:* Determine the conjugate base for each of these acids.)

17.10 | For each of the following acids, write the equation for its ionization in water and the appropriate expression for K_a: (a) $HCHO_2$, (b) $(CH_3)_2NH_2^+$, (c) $H_2PO_4^-$.

For weak acids, values of K_a are usually quite small and can be conveniently represented in a logarithmic form similar to pH. Thus, we can define the **pK_a** of an acid as

$$pK_a = -\log K_a$$

The strength of a weak acid is determined by its value of K_a; the larger the K_a, the stronger and more fully ionized the acid. Because of the negative sign in the defining equation for pK_a, the stronger the acid, the *smaller* is its value of pK_a. The values of K_a and pK_a for some typical weak acids are given in Table 17.2. A more complete list is located in Appendix C.8.

- Also, $K_a = \text{antilog}(-pK_a)$ or $K_a = 10^{-pK_a}$

- The values of K_a for strong acids are very large and are not tabulated. For many strong acids, K_a values have not been measured.

Practice Exercises

17.11 | Use Table 17.2 to find all the acids that are stronger than acetic acid and weaker than formic acid. (*Hint:* It may be easier to focus on the K_a values since they are directly related to acid strength.)

17.12 | Two acids, H*A* and H*B*, have pK_a values of 3.16 and 4.14, respectively. Which is the stronger acid? What are the K_a values for these acids?

Table 17.2 K_a and pK_a Values for Weak Monoprotic Acids at 25 °C

Name of Acid	Formula	K_a	pK_a
Iodic acid	HIO_3	1.7×10^{-1}	0.77
Chloroacetic acid	$HC_2H_2O_2Cl$	1.4×10^{-3}	2.85
Nitrous acid	HNO_2	4.6×10^{-4}	3.34
Hydrofluoric acid	HF	3.5×10^{-4}	3.46
Cyanic acid	$HOCN$	2×10^{-4}	3.7
Formic acid	$HCHO_2$	1.8×10^{-4}	3.74
Barbituric acid	$HC_4H_3N_2O_3$	9.8×10^{-5}	4.01
Hydrazoic acid	HN_3	2.5×10^{-5}	4.60
Acetic acid	$HC_2H_3O_2$	1.8×10^{-5}	4.74
Butanoic acid	$HC_4H_7O_2$	1.5×10^{-5}	4.82
Propanoic acid	$HC_3H_5O_2$	1.3×10^{-5}	4.89
Hypochlorous acid	$HOCl$	3.0×10^{-8}	7.52
Hydrocyanic acid	HCN	4.9×10^{-10}	9.31
Phenol	HC_6H_5O	1.3×10^{-10}	9.89
Hydrogen peroxide	H_2O_2	2.4×10^{-12}	11.62

Reaction of a Weak Base with Water

As with weak acids, all weak bases behave in a similar manner in water. They are weak Brønsted bases and are therefore proton acceptors. Examples are ammonia, NH_3, and acetate ion, $C_2H_3O_2^-$. Their reactions with water are

$$NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$$

$$C_2H_3O_2^- + H_2O \rightleftharpoons HC_2H_3O_2 + OH^-$$

Notice that in each instance, the base reacts with water to give OH^- and the corresponding conjugate acid. We can also represent these reactions by a general equation. If we represent the base by the symbol B, the reaction is

General equation for the ionization of a weak base

$$B + H_2O \rightleftharpoons BH^+ + OH^- \tag{17.11}$$

(As with weak acids, B does not have to be electrically neutral.) This yields the equilibrium law, where water is omitted as usual. We have a new equilibrium constant that is called the **base ionization constant,** with the symbol $\boldsymbol{K_b}$.

- K_b is also called the ***base dissociation constant.***

$$K_b = \frac{[BH^+][OH^-]}{[B]} \tag{17.12}$$

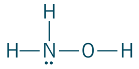
To illustrate, let's write the ionization reaction for the weak base, propylamine, $CH_3CH_2CH_2NH_2$.

$$CH_3CH_2CH_2NH_2 + H_2O \rightleftharpoons CH_3CH_2CH_2NH_3{}^+ + OH^-$$

The corresponding equilibrium law is

$$K_b = \frac{[CH_3CH_2CH_2NH_3{}^+][[OH^-]}{[CH_3CH_2CH_2NH_2]}$$

Practice Exercises



$$H{-}\overset{\displaystyle H}{\overset{|}{N}}{-}O{-}H$$

hydroxylamine, NH_2OH

17.13 | For each of the following bases, write the equation for its ionization in water and the appropriate expression for K_b. (*Hint:* See Equation 17.12.) (a) $(CH_3)_3N$ (trimethylamine), (b) $SO_3{}^{2-}$ (sulfite ion), (c) NH_2OH (hydroxylamine)

17.14 | Write the ionization reaction, and the K_b expression, when each of the following amphiprotic substances acts as a base: (a) HS^-, (b) $H_2PO_4{}^-$, (c) $HPO_4{}^{2-}$, (d) $HCO_3{}^-$, (e) $HSO_3{}^-$.

Because the K_b values for weak bases are usually small numbers, the same kind of logarithmic notation is often used to represent their equilibrium constants. Thus, $\boldsymbol{pK_b}$ is defined as

- Also, K_b = antilog $(-pK_b)$ or $K_b = 10^{-pK_b}$

$$pK_b = -\log K_b$$

Table 17.3 lists some molecular bases and their corresponding values of K_b and pK_b. A more complete list is located in Appendix C.8.

- Tables of ionization constants usually give values for only the molecular member of an acid–base pair.

Table 17.3 **K_b and pK_b Values for Weak Molecular Bases at 25 °C**

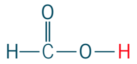
Name of Base	Formula	K_b	pK_b
Butylamine	$C_4H_9NH_2$	5.9×10^{-4}	3.23
Methylamine	CH_3NH_2	4.4×10^{-4}	3.36
Ammonia	NH_3	1.8×10^{-5}	4.74
Strychnine	$C_{21}H_{22}N_2O_2$	1.8×10^{-6}	5.74
Morphine	$C_{17}H_{19}NO_3$	1.6×10^{-6}	5.80
Hydrazine	N_2H_4	1.3×10^{-6}	5.89
Hydroxylamine	$HONH_2$	1.1×10^{-8}	7.96
Pyridine	C_5H_5N	1.7×10^{-9}	8.87
Aniline	$C_6H_5NH_2$	3.9×10^{-10}	9.41

The Product of K_a and K_b

Formic acid, $HCHO_2$ (a substance partly responsible for the sting of a fire ant), is a typical weak acid that ionizes according to the equation

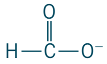
$$HCHO_2 + H_2O \rightleftharpoons H_3O^+ + CHO_2^-$$

■ Formic acid and formate ion have the structures



$$H{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}O{-}H$$

formic acid, $HCHO_2$
(Acidic hydrogen shown in red.)



$$H{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}O^-$$

formate ion, CHO_2^-

As you've seen, we write its K_a expression as

$$K_a = \frac{[H^+][CHO_2^-]}{[HCHO_2]}$$

The conjugate base of formic acid is the formate ion, CHO_2^-, and when a solute that contains this ion (e.g., $NaCHO_2$) is dissolved in water, the solution is slightly basic. In other words, the formate ion acts as a weak base since it is the conjugate base of formic acid. The reaction of formate ions with water is

Often the formula for formic acid is written HCOOH to emphasize its molecular structure. In this chapter we will write the formulas for acids with the acidic hydrogens first in the formula, which is why we've given the formula for formic acid as $HCHO_2$.

$$CHO_2^- + H_2O \rightleftharpoons HCHO_2 + OH^-$$

The K_b expression for this base is

$$K_b = \frac{[HCHO_2][OH^-]}{[CHO_2^-]}$$

There is an important relationship between the equilibrium constants for this conjugate acid–base pair: the product of K_a times K_b equals K_w. We can see this by multiplying the mass action expressions above.

$$K_a \times K_b = \frac{[H^+]\cancel{[CHO_2^-]}}{\cancel{[HCHO_2]}} \times \frac{\cancel{[HCHO_2]}[OH^-]}{\cancel{[CHO_2^-]}} = [H^+][OH^-] = K_w$$

In fact, this same relationship exists for *any* acid–base conjugate pair.

For *any* acid–base conjugate pair:

$$K_a \times K_b = K_w \tag{17.13}$$

Inverse relationship between K_a and K_b

Another useful relationship, which can be derived by taking the negative logarithm of each side of Equation 17.13, is

$$pK_a + pK_b = pK_w = 14.00 \qquad \text{(at 25 °C)} \tag{17.14}$$

Relationship between pK_a and pK_b

There are some important consequences of the relationship expressed in Equation 17.13. One is that it is not necessary to tabulate both K_a and K_b for the members of an acid–base pair; if one K is known, the other can be calculated. For example, the K_a for $HCHO_2$ and the K_b for NH_3 will be found in most tables, and those tables usually will not contain the K_b for CHO_2^- or the K_a for NH_4^+. If they are needed, we can calculate them using Equation 17.13.

■ $-\log (K_a \times K_b) = -\log K_w$
$(-\log K_a) + (-\log K_b) = -\log K_w$
$pK_a + pK_b = pK_w$

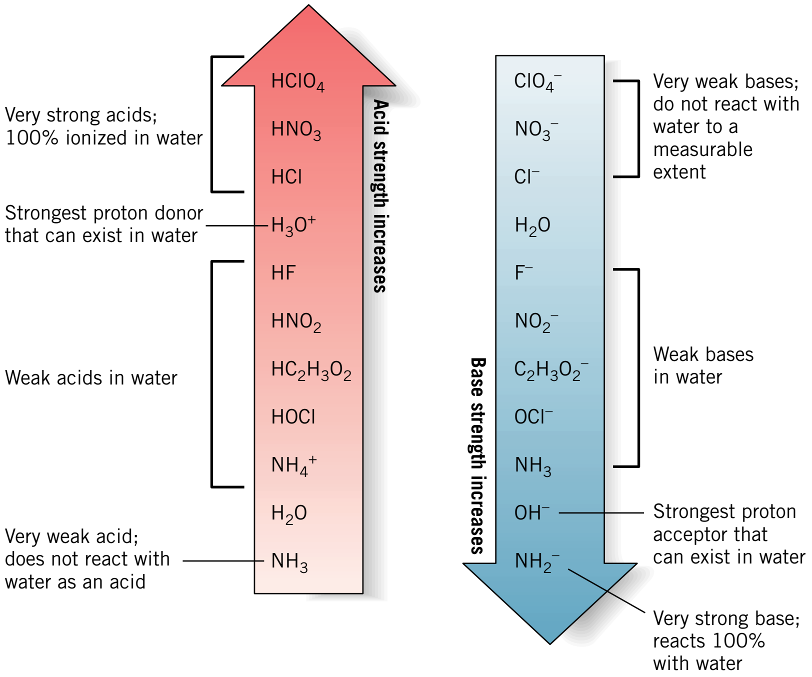
Practice Exercises

17.15 | The methylammonium ion $CH_3NH_3^+$ has a K_a of 2.3×10^{-11}. What is the K_b for the base methylamine? (*Hint:* Recall that K_a and K_b are inversely proportional to each other.)

17.16 | The value of K_b for the CHO_2^- ion is 5.5×10^{-11}. What is the value of K_a for $HCHO_2$?

Another interesting and useful observation is that *there is an inverse relationship between the strengths of the acid and base members of a conjugate pair*. This is illustrated graphically in Figure 17.3. Because the product of K_a and K_b is a constant, the larger the value of K_a the smaller is the value of K_b. In other words, *the stronger the acid, the weaker is its conjugate base* (a fact that we noted in Chapter 16 in our discussion of the strengths of Brønsted acids and bases). We will say more about this relationship in Section 17.6.

Figure 17.3 | **The relative strengths of conjugate acid–base pairs.** The stronger the acid is, the weaker is its conjugate base. The weaker the acid is, the stronger is its conjugate base. Very strong acids are 100% ionized and their conjugate bases do not react with water to any measurable extent.



Very strong acids; 100% ionized in water
Strongest proton donor that can exist in water
Weak acids in water
Very weak acid; does not react with water as an acid
$HClO_4$
HNO_3
HCl
H_3O^+
HF
HNO_2
$HC_2H_3O_2$
HOCl
NH_4^+
H_2O
NH_3
Acid strength increases
Base strength increases
ClO_4^-
NO_3^-
Cl^-
H_2O
F^-
NO_2^-
$C_2H_3O_2^-$
OCl^-
NH_3
OH^-
NH_2^-
Very weak bases; do not react with water to a measurable extent
Weak bases in water
Strongest proton acceptor that can exist in water
Very strong base; reacts 100% with water

17.4 | Determining K_a and K_b Values

Our goal in this section is to develop a general strategy for dealing quantitatively with the equilibria of weak acids and bases in water. Generally, these calculations fall into two categories. The first involves calculating the value of K_a or K_b from the initial concentration of the acid or base and the measured pH of the solution (or some other data about the equilibrium composition of the solution). The second involves calculating equilibrium concentrations given K_a or K_b and initial concentrations, which we consider in Section 17.5.

Methods Using Initial Concentrations and Equilibrium Data

In problems of this type, our *first* goal is to obtain numerical values for *all* the equilibrium concentrations that are needed to evaluate the mass action expression in the definition of K_a or K_b. (The reason, of course, is that at equilibrium the reaction quotient, Q, equals the equilibrium constant.) We are usually given the molar concentration of the acid or base as it would appear on the label of a bottle containing the solution. Also provided is information from which we can obtain directly at least one of the equilibrium concentrations. Thus, we might be given the measured pH of the solution, which provides an estimate of the equilibrium concentration of H^+. (Equilibrium is achieved rapidly in these solutions, so when we measure the pH, the value obtained can be used to calculate the equilibrium concentration of H^+.) Alternatively, we might be given the **percentage ionization** of the acid or base, which we define as follows:

TOOLS

Percentage ionization

$$\text{percentage ionization} = \frac{\text{moles ionized per liter}}{\text{moles available per liter}} \times 100\% \qquad \text{(17.15)}$$

Let's look at some examples that illustrate how to determine K_a and K_b from the kind of data mentioned.

Example 17.1

Calculating K_a and pK_a from pH

Lactic acid ($HC_3H_5O_3$), which is present in sour milk, also gives sauerkraut its tartness. It is a monoprotic acid. In a 0.100 *M* solution of lactic acid, the pH is 2.44 at 25 °C. Calculate the K_a and pK_a for lactic acid at this temperature.

For some, nothing goes better on a hot dog than sauerkraut and mustard. Lactic acid gives sauerkraut its sour taste. *(Susan Kaprov)*

Analysis: In any problem involving the ionization of a weak acid or base, the first step is to write the balanced chemical equation. From the equation we can write the correct equilibrium law and perform any necessary stoichiometric reasoning, with the help of a concentration table if needed.

We're given the pH of the solution, so we can use this to calculate the H^+ concentration. This will be the *equilibrium* [H^+]; as noted previously, equilibrium is reached rapidly in solutions of acids and bases. (It's important to remember that values that satisfy the K_a expression are *equilibrium* values only.)

Assembling the Tools: We're told it's an acid, so we'll begin by writing the equilibrium equation, and then the K_a expression, as we have done in the practice exercises,

$$HC_3H_5O_3 \rightleftharpoons H^+ + C_3H_5O_3^- \qquad K_a = \frac{[H^+][C_3H_5O_3^-]}{[HC_3H_5O_3]}$$

Equation 17.5 is needed to calculate [H^+], and we will construct and use a concentration table using Example 15.8 on page 720 as our guide.

Solution: Looking at our tools, we see that we need the equilibrium values for [H^+], [$C_3H_5O_3^-$], and [$HC_3H_5O_3$] to calculate K_a. At this point it will help to set up a concentration table. To obtain the initial concentrations we see that the only solute is $HC_3H_5O_3$, (0.100 *M*), so the only source of the ions, H^+ and $C_3H_5O_3^-$, is the ionization of the acid. Their concentrations are listed initially as zero. (Remember that, in a solution of an acid, it is safe to ignore the small amount of H^+ contributed by the autoionization of water.) As we did in Example 15.8, the change in concentrations will be represented as the unknown *x*. Adding the initial concentration and change rows gives us the terms for the equilibrium concentrations. These entries are shown in black.

We now find the [H^+] from pH. This gives us the *equilibrium* value of [H^+].

■ Remember, the measured pH *always* gives the equilibrium concentration of H^+.

$$[H^+] = 10^{-2.44}$$
$$= 0.0036\ M$$

This value is the equilibrium concentration of H^+ (shown in red). From this we see that *x* must be 0.0036. Knowing *x*, we can calculate the equilibrium concentrations of $HC_3H_5O_3$ and $C_3H_5O_3^-$ as shown in green in the table.

	$HC_3H_5O_3$	$\rightleftharpoons$	H^+	+	$C_3H_5O_3^-$
Initial concentrations (*M*)	0.100		0		0
Changes in concentrations (*M*)	$-x$		$+x$		$+x$
Equilibrium conc. (*M*)	$(0.100 - x)$		x		x
Equilibrium concentration values based on pH	$(0.100 - 0.0036) = 0.096$ (correctly rounded)		0.0036		0.0036

The last row of data now contains the equilibrium concentrations that we now use to calculate K_a. We simply substitute them into the K_a expression.

$$K_a = \frac{(3.6 \times 10^{-3})(3.6 \times 10^{-3})}{0.096} = 1.4 \times 10^{-4}$$

Thus the acid ionization constant for lactic acid is 1.4×10^{-4}. To find pK_a, we take the negative logarithm of K_a.

$$pK_a = -\log K_a = -\log (1.4 \times 10^{-4}) = 3.85$$

Is the Answer Reasonable? Weak acids have small ionization constants, so the value we obtained for K_a seems to be reasonable. *We should also check the entries in the concentration table to be sure they are reasonable.* For example, the "changes" for the ions are both positive, meaning both of their concentrations are increasing. This is the way it *must* be because neither ion can have a concentration less than zero. The changes are caused by the ionization reaction, so they both have to change in the same direction. Also, we have the concentration of the molecular acid decreasing, as it should if the ions are being formed by the ionization.

Sometimes we have the opportunity to determine the percentage ionization of a substance. Obvious examples are osmotic pressure measurements and measurements of freezing point depression and boiling point elevations that we discussed in Section 13.7. The following example illustrates how we can determine the value of K_b of a base such as methylamine when we know its percentage ionization.

Example 17.2

Calculating K_b and pK_b from the Percentage Ionization

Methylamine is responsible in part for the fishy aroma of pickled herring. *(Andy Washnik)*

Methylamine, CH_3NH_2, is a weak base and one of several substances that give herring brine its pungent odor. In 0.100 *M* CH_3NH_2, only 6.4% of the base is ionized. What are K_b and pK_b of methylamine?

Analysis: In this problem we've been given the percentage ionization of the base. We will use this to calculate the equilibrium concentrations of the ions in the solution. After we know these, solving the problem follows the same path as in the preceding example.

Assembling the Tools: As in the previous example, we need the balanced chemical equation (see the format for a weak base in Equation 17.11) so we can write the equilibrium law (see the format for the equilibrium law of a weak base in Equation 17.12). These are written as

$$CH_3NH_2 + H_2O \rightleftharpoons CH_3NH_3^+ + OH^-$$

$$K_b = \frac{[CH_3NH_3^+][OH^-]}{[CH_3NH_2]}$$

We will also use the percentage ionization, Equation 17.15, to calculate at least one of the equilibrium concentrations.

Solution: Now that we have our tools, we can start constructing the equilibrium table with the chemical equation and the appropriate rows and columns. We next enter the initial concentrations as shown in black. The initial concentrations are those concentrations before any reaction takes place. Therefore the concentrations of the ions are listed as zeros. Usually, we use the variable *x* to indicate the changes expected, in the change row, and the equilibrium concentrations in the last row, which we recall is the sum of the first two rows. However, the percentage composition allows us to complete the table directly.

The percentage ionization tells us that 6.4% of the CH_3NH_2 has reacted. Entering the information into Equation 17.15 gives us

$$\frac{\text{moles per liter of } CH_3NH_2 \text{ ionized}}{0.100\ M} \times 100\% = 6.4\%$$

Therefore, the number of moles per liter of the base that has ionized at equilibrium in this solution is:

$$\text{moles per liter of } CH_3NH_2 \text{ ionized} = \frac{6.4\% \times 0.100\ M}{100\%} = 0.0064\ M$$

■ To find 6.4% of 0.100 *M*, Equation 17.15 has been rearranged.

This value represents the *decrease* in the concentration of CH_3NH_2, which is -0.0064 moles L^{-1} of CH_3NH_2. We can now use this change in $[CH_3NH_2]$ to determine the concentrations of the other species. We find that $[CH_3NH_2^+]$ and $[OH^-]$ are both 0.0064 mol L^{-1}. Let's enter these values directly into the concentration table.

	H_2O	+	CH_3NH_2	⇌	$CH_3NH_3^+$	+	OH^-
Initial concentrations (*M*)			0.100		0		0
Changes in concentrations (*M*)			−0.0064		0.0064		0.0064
Equilibrium conc. (*M*)			(0.100 − 0.0064)		0.0064		0.0064

Now we can calculate K_b by substituting equilibrium quantities into the mass action expression.

$$K_b = \frac{(0.0064)(0.0064)}{(0.100 - 0.0064)} = 4.4 \times 10^{-4}$$

and

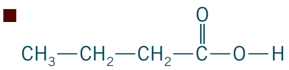
$$pK_b = -\log(4.4 \times 10^{-4}) = 3.36$$

Is the Answer Reasonable? First, the value of K_b is small, so that suggests we've probably worked the problem correctly. We can also check the "Change" row to be sure the algebraic signs are correct. Both initial concentrations start out at zero, so they must both increase, which they do. The change for the CH_3NH_2 is opposite in sign to that for the ions, and that's as it should be. Therefore, we appear to have set up the problem correctly.

Practice Exercises

17.17 | Salicylic acid reacts with acetic acid to form aspirin, acetyl salicylic acid. A 0.200 molar solution of salicylic acid has a pH of 1.83. Calculate the K_a and pK_a of salicylic acid. (*Hint:* Convert the pH to $[H^+]$ first.)

17.18 | When butter turns rancid, its foul odor is mostly that of butanoic acid, $HC_4C_7O_2$, a weak monoprotic acid similar to acetic acid in structure. In a 0.0100 *M* solution of butanoic acid at 20 °C, the acid is 4.0% ionized. Calculate the K_a and pK_a of butanoic acid at this temperature.



$CH_3-CH_2-CH_2-C(=O)-O-H$

butanoic acid
$HC_4H_7O_2$

17.19 | Few substances are more effective in relieving intense pain than morphine. Morphine is an alkaloid—an alkali-like compound obtained from plants—and alkaloids are all weak bases. In 0.010 *M* morphine, the pOH is 3.90. Calculate the K_b and pK_b for morphine. (You don't need to know the formula for morphine, just that it's a base. Use whatever symbol you want to write the equation.)

17.5 | pH of Weak Acid and Weak Base Solutions

It is interesting to understand some methods for determining the K_a and K_b values. Someday you may synthesize an acid or base and have the need to characterize its properties by such an analysis. However, it is more common to use those values for everyday laboratory calculations of pH or $[H^+]$.

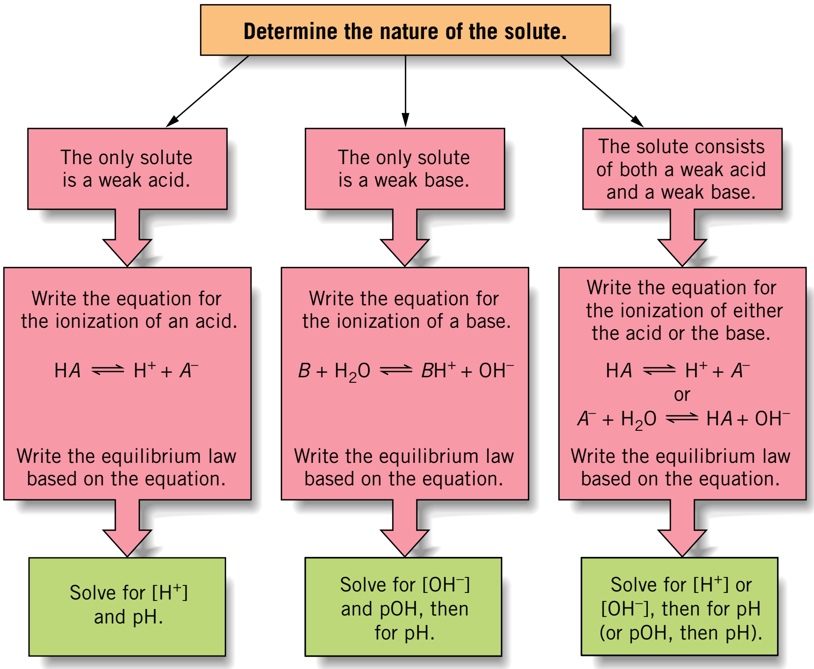
Calculating Equilibrium Concentrations

These calculations are not especially difficult, providing you start off on the right foot. The key to success is examining the statement of the problem carefully so you can construct the correct chemical equation, which will then lead you to write the equilibrium law that's required to obtain the solution. With this in mind, let's take an overview of the "landscape" to develop a method for selecting the correct approach to the problem.

Almost any problem in which you are given a value of K_a or K_b falls into one of three categories: (1) the aqueous solution contains a weak acid as its *only* solute, (2) the solution contains a weak base as its *only* solute, or (3) the solution contains *both* a weak acid and its conjugate base. The approach we take for each of these conditions is described below and is summarized in Figure 17.4.

1. If the solution contains only a weak acid as the solute, then the problem *must* be solved using K_a. This means that the correct chemical equation for the problem is the ionization of the weak acid. It also means that if you are given the K_b for the acid's conjugate base, you will have to calculate the K_a using Equation 17.13 in order to solve the problem.
2. If the solution contains only a weak base, the problem *must* be solved using K_b. The correct chemical equation is for the ionization of the weak base. If the problem gives you K_a for the base's conjugate acid, then you must use Equation 17.13 to calculate K_b to solve the problem.

■ Conditions 1 and 2 apply to solutions of weak molecular acids and bases and to solutions of salts that contain an ion that is an acid or a base. Condition 3 applies to solutions called *buffers*, which are discussed in Section 17.7.



Determine the nature of the solute.
The only solute is a weak acid.
The only solute is a weak base.
The solute consists of both a weak acid and a weak base.
Write the equation for the ionization of an acid.
$HA \rightleftharpoons H^+ + A^-$
Write the equilibrium law based on the equation.
Write the equation for the ionization of a base.
$B + H_2O \rightleftharpoons BH^+ + OH^-$
Write the equilibrium law based on the equation.
Write the equation for the ionization of either the acid or the base.
$HA \rightleftharpoons H^+ + A^-$
or
$A^- + H_2O \rightleftharpoons HA + OH^-$
Write the equilibrium law based on the equation.
Solve for $[H^+]$ and pH.
Solve for $[OH^-]$ and pOH, then for pH.
Solve for $[H^+]$ or $[OH^-]$, then for pH (or pOH, then pH).

Figure 17.4 | **Determining how to proceed in acid–base equilibrium problems.** The nature of the solute species determines how the problem is approached. Following this diagram will get you started in the right direction.

3. Solutions that contain two solutes, one a weak acid and the other its conjugate base, have some special properties that we will discuss later. (Such solutions are called *buffers.*) To work problems for these kinds of mixtures, we can use *either* K_a or K_b—it doesn't matter which we use, because we will obtain the same answers either way. However, if we elect to use K_a, then the chemical equation we use must be for the ionization of the acid. If we decide to use K_b, then the correct chemical equation is for the ionization of the base. Usually, the choice of whether to use K_a or K_b is made on the basis of which constant is most readily available.

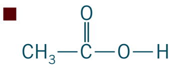
When you begin to solve a problem, decide which of the three conditions above applies. If necessary, keep Figure 17.4 handy to guide you in your decision, so that you select the correct path to follow.

Simplifications in Calculations

In Chapter 15 you learned that when the equilibrium constant is small, it is frequently possible to make simplifying assumptions that greatly reduce the algebraic effort in obtaining equilibrium concentrations. For many acid–base equilibrium problems such simplifications are particularly useful.

Let's consider a solution of 1.0 *M* acetic acid, $HC_2H_3O_2$, for which $K_a = 1.8 \times 10^{-5}$. What is involved in determining the equilibrium concentrations in the solution?

To answer this question, we begin with the chemical equation for the equilibrium. Because the only solute in the solution is the weak acid, we must use K_a and therefore write the equation for the ionization of the acid. Let's use the simplified version.



$\mathrm{CH_3{-}\overset{\overset{O}{\|}}{C}{-}O{-}H}$

acetic acid
$HC_2H_3O_2$

$$HC_2H_3O_2 \rightleftharpoons H^+ + C_2H_3O_2^-$$

The equilibrium law is

$$K_a = \frac{[H^+][C_2H_3O_2^-]}{[HC_2H_3O_2]} = 1.8 \times 10^{-5}$$

We will take the given concentration, 1.0 *M*, to be the initial concentration of $HC_2H_3O_2$ (i.e., the concentration of the acid before any ionization has occurred). This concentration will decrease slightly as the acid ionizes and the ions form. If we let x be the amount of acetic acid that ionizes per liter, then the $HC_2H_3O_2$ concentration will decrease by x (its change will be $-x$) and the H^+ and $C_2H_3O_2^-$ concentrations will each increase by x (their changes will be $+x$). We can now construct the following concentration table.

	$HC_2H_3O_2$	$\rightleftharpoons$	H^+	$+$	$C_2H_3O_2^-$
Initial concentrations (*M*)	1.0		0		0
Changes in concentrations (*M*)	$-x$		$+x$		$+x$
Equilibrium conc. (*M*)	$1.0 - x$		x		x

The initial concentrations of the ions are set equal to zero because none of them have been supplied by a solute.

The values in the last row of the table should satisfy the equilibrium law. When they are substituted into the mass action expression we obtain

$$\frac{(x)(x)}{1.0 - x} = 1.8 \times 10^{-5}$$

This equation involves a term in x^2, and it could be solved using the quadratic formula as we did in Chapter 15. However, this and many other similar calculations involving weak acids and bases can be simplified. Let's look at the reasoning.

The equilibrium constant, 1.8×10^{-5}, is quite small, so we can anticipate that very little of the acetic acid will be ionized at equilibrium. This means x will be very small, so we make the approximation $(1.0 - x) \approx 1.0$. Replacing $1.0 - x$ with 1.0 yields the equation (See Section 15.8, page 726, where we first introduced this type of approximation.)

■ We are assuming that when x is subtracted from 1.0 and *the result is rounded to the correct number of significant figures*, the answer will round to 1.0.

$$\frac{(x)(x)}{1.0 - x} \approx \frac{x^2}{1.0} = 1.8 \times 10^{-5}$$

Solving for x gives $x = 0.0042\ M$. We see that the value of x is indeed negligible compared to $1.0\ M$ (i.e., if we subtract $0.0042\ M$ from $1.0\ M$ and round correctly, we obtain $1.0\ M$).

Notice that when we make this approximation, *the initial concentration of the acid is used as if it were the equilibrium concentration*. The approximation is valid when the equilibrium constant is small and the concentrations of the solutes are reasonably high—conditions that will apply to most situations you will encounter in this chapter. After a few examples we will discuss the conditions under which these approximations are not valid.

Let's look at some typical acid–base equilibrium problems.

Example 17.3

Calculating the Values of [H$^+$] and pH of a Weak Acid Solution from Its K_a Value and Initial Concentration

The calcium salt of propionic acid, calcium propionate, is used as a preservative in baked products. *(Andy Washnik)*

A student planned an experiment that would use $0.10\ M$ propionic acid, $HC_3H_5O_2$. Calculate the value of [H$^+$] and the pH for this solution. For propionic acid, $K_a = 1.3 \times 10^{-5}$.

■ **Analysis:** First, we note that the only solute in the solution is a weak acid, so we know we will have to use K_a and write the equation for the ionization of the acid.

■ **Assembling the Tools:** The balanced equation and equilibrium law we need are

$$HC_3H_5O_2 \rightleftharpoons H^+ + C_3H_5O_2^-$$

$$K_a = \frac{[H^+][C_3H_5O_2^-]}{[HC_3H_5O_2]}$$

■ 
$$CH_3-CH_2-\overset{\overset{O}{\|}}{C}-O-H$$

propionic acid

$HC_3H_5O_2$

We will calculate the [H$^+$], starting with the concentration table, and then use Equation 17.4 to obtain the pH.

■ **Solution:** We'll start off by making a concentration table using the methods described above. In this table the initial concentration of the acid is $0.10\ M$, and the initial concentrations of the ions are both $0\ M$. These values are entered in the first line of the table.

	$HC_3H_5O_2$	$\rightleftharpoons$	H^+	$+$	$C_3H_5O_2^-$
Initial concentrations (M)	0.10		0		0
Changes in concentrations (M)	$-x$		$+x$		$+x$
Equilibrium conc. (M)	$(0.10 - x) \approx 0.10$		x		x

From the balanced chemical equation we know that the equilibrium concentrations of H$^+$ and $C_3H_5O_2^-$ are the same; they are represented by x. Anticipating that x will be very small, we make the simplifying approximation $(0.10 - x) \approx 0.10$, so we take the equilibrium concentration of $HC_3H_5O_2$ to be 0.10 M. Substituting these quantities into the K_a expression gives

$$K_a = \frac{[H^+][C_3H_5O_2^-]}{[HC_3H_5O_2]} = \frac{(x)(x)}{(0.10 - x)} \approx \frac{(x)(x)}{(0.10)} = 1.3 \times 10^{-5}$$

Solving for x yields

$$x = 1.2 \times 10^{-3}$$

Because $x = [H^+]$,

$$[H^+] = 1.2 \times 10^{-3}\ M$$

Finally, we calculate the pH

$$\begin{aligned} pH &= -\log(1.2 \times 10^{-3}) \\ &= 2.92 \end{aligned}$$

■ **Is the Answer Reasonable?** First, we check to be sure our assumption was reasonable, and it is (0.10 − 0.0012 = 0.10 when rounded correctly). Also we see that the calculated pH is less than 7. This tells us that the solution is acidic, which it should be for a solution of an acid. Also, the pH is higher than it would be if the acid were strong. (A 0.10 M solution of a strong acid would have $[H^+] = 0.10\ M$ and pH = 1.0.) If we wish to further check the accuracy of the calculation, we can substitute the calculated equilibrium concentrations into the mass action expression. If the calculated quantities are correct, the reaction quotient should equal K_a. Let's do the calculation.

$$\frac{[H^+][C_3H_5O_2^-]}{[HC_3H_5O_2]} = \frac{(x)(x)}{(0.10)} = \frac{(1.2 \times 10^{-3})^2}{0.10} = 1.4 \times 10^{-5} = K_a$$

This is very close to the given K_a and we judge that we have done the calculation correctly.

Practice Exercises

17.20 | Benzoic acid, $HC_6H_5CO_2$, is a monoprotic acid (only one H^+ ionizes) with a $K_a = 6.5 \times 10^{-5}$. Calculate $[H^+]$ and the pH of a 0.023 M solution of benzoic acid. (*Hint:* Consider using an assumption to solve this rather than the quadratic formula.)

17.21 | Nicotinic acid, $HC_6H_4NO_2$, is a B vitamin. It is also a weak acid with $K_a = 1.4 \times 10^{-5}$. Calculate $[H^+]$ and the pH of a 0.050 M solution of $HC_2H_4NO_2$.

When we have the initial concentration of a molecular base, the determination of pH involves the same steps as we used in Example 17.3. However, we need to be careful to remember that the calculation yields the hydroxide ion concentration. That requires an additional conversion step from pOH to pH as shown in the following example.

Example 17.4

Calculating the pH of a Solution and the Percentage Ionization of the Solute

A solution of hydrazine, N_2H_4, has a concentration of 0.25 M. What is the pH of the solution, and what is the percentage ionization of the hydrazine? Hydrazine has $K_b = 1.3 \times 10^{-6}$.

■ **Analysis:** Hydrazine must be a weak base, because we have its value of K_b (the "b" in K_b tells us this is a *base* ionization constant). Since hydrazine is the only solute in the solution, we will have to write the equation for the ionization of a weak base and then set up the K_b expression.

Assembling the Tools: To write the chemical equation we need the formula for the conjugate acid of N_2H_4. It has one additional H^+, so its formula is $N_2H_5^+$. Now we write the balanced chemical equation and the equilibrium law as

$$N_2H_4 + H_2O \rightleftharpoons N_2H_5^+ + OH^-$$

$$K_b = \frac{[N_2H_5^+][OH^-]}{[N_2H_4]}$$

We will use a concentration table and appropriate assumptions.

To calculate the percentage ionization, we need to use Equation 17.15 on page 784. This requires that we determine the number of moles per liter of the base that has ionized. The concentration table will help us perform this calculation correctly.

Solution: Let's once again construct the concentration table. The only sources of $N_2H_5^+$ and OH^- are the ionization of the N_2H_4, so their initial concentrations are both zero. They will form in equal amounts, so we let their changes in concentration equal $+x$. The concentration of N_2H_4 will decrease by x, so its change is $-x$.

H_2O +	N_2H_4	$\rightleftharpoons$	$N_2H_5^+$	+	OH^-
Initial concentrations (M)	0.25		0		0
Changes in concentrations (M)	$-x$		$+x$		$+x$
Equilibrium conc. (M)	$(0.25 - x) \approx 0.25$		x		x

Because K_b is so small, $[N_2H_4] \approx 0.25\ M$. (As before, we assume the initial concentration will be effectively the same as the equilibrium concentration, an approximation that we expect to be valid.) Substituting into the K_b expression,

$$\frac{(x)(x)}{0.25 - x} \approx \frac{(x)(x)}{0.25} = 1.3 \times 10^{-6}$$

Solving for x gives: $x = 5.7 \times 10^{-4}$. This value represents the hydroxide ion concentration, from which we can calculate the pOH.

$$\text{pOH} = -\log(5.7 \times 10^{-4}) = 3.24$$

The pH of the solution can then be obtained from the relationship

$$\text{pH} + \text{pOH} = 14.00$$

Thus,

$$\text{pH} = 14.00 - 3.24 = 10.76$$

For the percent ionization we look to the concentration table and see that the value of x represents the amount of N_2H_4 that ionizes per liter (i.e., the change in the N_2H_4 concentration). Therefore,

$$\text{percentage ionization} = \frac{5.7 \times 10^{-4}\ M}{0.25\ M} \times 100\%$$
$$= 0.23\%$$

The base is 0.23% ionized.

Are the Answers Reasonable? First, we can quickly check to see whether the value of x satisfies our assumption and it does $(0.25 - 0.00057 = 0.25)$. The value of the hydroxide ion concentration is small and the pH indicates a basic solution. Additionally the small concentration of hydroxide ions agrees with the small percentage ionization we calculated. We could use our equilibrium concentrations to calculate K_b as in the previous example.

Practice Exercises

17.22 | Aniline, $C_6H_5NH_2$, is a precursor for many dyes used to color fabrics, known as aniline dyes. Aniline has a K_b of 3.9×10^{-10}. What is the pOH of a 0.025 molar solution of aniline? (*Hint:* Calculate the OH^- concentration.)

17.23 | Pyridine, C_5H_5N, is a bad-smelling liquid for which $K_b = 1.7 \times 10^{-9}$. What is the pH of a 0.010 M aqueous solution of pyridine?

17.24 | Phenol is an acidic organic compound for which $K_a = 1.3 \times 10^{-10}$. What is the pH of a 0.15 M solution of phenol in water?

When Simplifications Fail

In the examples we studied above, we made a simplification by assuming that we could use the initial concentration as the equilibrium concentration of the weak acid or weak base. We confirmed this assumption by observing that, if we correctly used the significant figure rules for subtraction, the initial concentration did not change when we accounted for the amount that ionized.

In some instances, we will calculate an answer where the initial concentration will change slightly when we subtract the amount that ionizes. In those cases we may want to use the quadratic formula or the method of successive approximations described in Appendix A.4. Since these two methods are tedious and have more steps that can introduce error, we might consider relaxing the rules for using our simplifications.

■ If the simplifications do not work, we can solve quadratic equations by using the quadratic formula. A detailed description of how to use the quadratic formula is given in Chapter 15, Example 15.10 on page 724.

When we ask ourselves how precise our pH calculations need to be, we find two factors to consider. First, most ionization constants only have two significant figures, therefore the hydrogen ion concentrations we calculate should have two significant figures. We recall that the uncertainty is usually taken as ±1 in the last digit of a measurement. The uncertainty of a two-digit number ranges from 1% to 10%. Second, the experimental determination of pH usually has an uncertainty of ± 0.02 pH units or ±5% in terms of hydrogen ion concentration. In general, there is usually little need to calculate a pH more precisely than we can measure it in the laboratory. These two sources of error tell us that any simplification that results in an error less than approximately ±5% will give us acceptable results. Without going into the detailed explanation, we find a simple rule for testing if a simplification will work. The rule states that a simplifying assumption will work if the initial concentration of a weak acid, C_{HA}, or a weak base, C_B, is more than 100 times the value of the ionization constant.[4]

$$C_{HA} > 100 \times K_a \qquad \text{or} \qquad C_B > 100 \times K_b$$

Since we can easily multiply a K_a or K_b by 100, we can test to see if our assumptions will work *before* we do the calculation.

TOOLS

Criteria for predicting when simplifying assumptions will work

17.6 | pH of Salt Solutions

When we study solutions of salts, we find that many have a neutral pH. Examples are NaCl and KNO_3. However, not all salt solutions behave this way. Some, such as $NaC_2H_3O_2$, are slightly basic while others, such as NH_4Cl, are slightly acidic. To understand this behavior, we have to examine how the ions of a salt can affect the pH of a solution.

In Section 17.3 you saw that weak acids and bases are not limited to molecular substances. For instance, NH_4^+ was given as an example of a weak acid, and $C_2H_3O_2^-$ was

---

[4] If we calculate the hydrogen ion concentration analytically, using the quadratic formula, we obtain the "true" value. We can compare that value to the concentration obtained by using a simplification and calculate the error as

$$\frac{[H^+]_{\text{simplification}} - [H^+]_{\text{quadratic}}}{[H^+]_{\text{quadratic}}} \times 100\% = \%\ \text{error}$$

When we relate this percent error to the ratio of C_a/K_a it is found that when this ratio is greater than 100, the error is less than approximately 5%.

cited as an example of a weak base. Ions such as these always come to us in compounds in which there are both a cation *and* an anion. Therefore, to place NH_4^+ in water, we need a salt such as NH_4Cl, and to place $C_2H_3O_2^-$ in water, we need a salt such as $NaC_2H_3O_2$.

Because a salt contains two ions, the pH of its solution can potentially be affected by either the cation or the anion, or perhaps even both. Therefore, we have to consider *both* ions if we wish to predict the effect of a salt on the pH of a solution.

Acidic Cations

If the cation of a salt is able to influence the pH of a solution, it does so by behaving as a weak acid. Not all cations are acidic, however, so let's look at the possibilities.

■ The reaction of a salt with water to give either an acidic or basic solution is sometimes called **hydrolysis**. Hydrolysis means *reaction with water.*

Conjugate Acids of Molecular Bases

The ammonium ion, NH_4^+, is the conjugate acid of the molecular base, NH_3. We have already learned that NH_4^+, supplied for example by NH_4Cl, is a weak acid. As seen in Figure 17.5, solutions of this salt have a pH lower than 7. The equation for the reaction as an acid is

$$NH_4^+(aq) + H_2O \rightleftharpoons NH_3(aq) + H_3O^+(aq)$$

Writing this in a simplified form, along with the K_a expression, we have

$$NH_4^+(aq) \rightleftharpoons NH_3(aq) + H^+(aq) \qquad K_a = \frac{[NH_3][H^+]}{[NH_4^+]}$$

Because the K_a values for ions are seldom tabulated, we would usually expect to calculate the K_a value using the relationship: $K_a \times K_b = K_w$. In Table 17.3 the K_b for NH_3 is given as 1.8×10^{-5}. Therefore,

$$K_a = \frac{K_w}{K_b} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

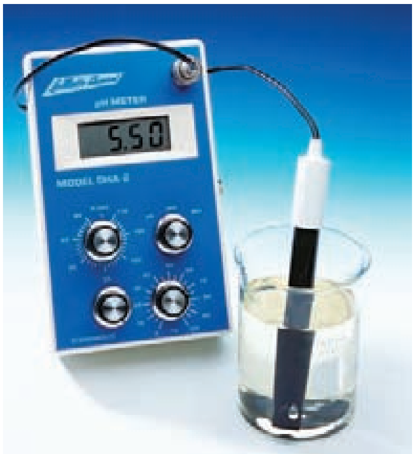


Figure 17.5 | **Ammonium ion as a weak acid.** The measured pH of a solution of the salt NH_4NO_3 is less than 7, which indicates the solution is acidic. Bromothymol blue, a pH indicator discussed in Section 17.9 (page 816) has been added and has a faint yellow color indicating an acid solution. *(Richard Megna/Fundamental Photographs.)*

Another example is the hydrazinium ion, $N_2H_5^+$, which is also a weak acid.

$$N_2H_5^+(aq) \rightleftharpoons N_2H_4(aq) + H^+(aq) \qquad K_a = \frac{[N_2H_4][H^+]}{[N_2H_5^+]}$$

The tabulated K_b for N_2H_4 is 1.3×10^{-6}. From this, the calculated value of K_a equals 7.7×10^{-9}.

These examples illustrate a general phenomenon:

TOOLS

Identifying acidic cations

| Cations that are the conjugate acids of molecular bases tend to be weakly acidic.

Cations that are not conjugate acids of molecular bases are generally metal ions such as Na^+, K^+, and Ca^{2+}. In Chapter 16 we learned that the cations of the Group 1A metals are extremely weak acids and are unable to affect the pH of a solution. Except for Be^{2+}, the cations of Group 2A also do not affect pH.

Basic Anions

When a Brønsted acid loses a proton, its conjugate base is formed. Thus Cl^- is the conjugate base of HCl, and $C_2H_3O_2^-$ is the conjugate base of $HC_2H_3O_2$.

$$HCl + H_2O \longrightarrow Cl^- + H_3O^+$$
$$HC_2H_3O_2 + H_2O \rightleftharpoons C_2H_3O_2^- + H_3O^+$$

Although both Cl^- and $C_2H_3O_2^-$ are bases, only the latter affects the pH of an aqueous solution. Our knowledge of conjugate acid–base pairs from Chapter 16 helps us undertand why.

Earlier you learned that there is an inverse relationship between the strength of an acid and its conjugate base—the stronger the acid, the weaker is the conjugate base. Therefore, when an acid is *extremely strong*, as in the case of HCl or other "strong" acids that are 100% ionized (such as HNO_3), the conjugate base is *extremely weak*—too weak to affect in a measurable way the pH of a solution. Consequently, we have the following generalization:

> The anion of a strong acid is too weak a base to influence the pH of a solution.

Acetic acid is much weaker than HCl, as evidenced by its value of K_a (1.8×10^{-5}). Because acetic acid is a weak acid, its conjugate base is much stronger than Cl^- and we can expect it to affect the pH (Figure 17.6). We can calculate the value of K_b for $C_2H_3O_2^-$ from the K_a for $HC_2H_3O_2$, also with the equation $K_a \times K_b = K_w$.

$$K_b = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

This leads to another conclusion:

> The anion of a weak acid is a weak base and can influence the pH of a solution. It will tend to make the solution basic.

TOOLS

Identifying basic anions

Acid–Base Properties of Salts

To decide if any given salt will affect the pH of an aqueous solution, we must examine each of its ions and see what it alone might do. There are four possibilities:

1. If neither the cation nor the anion can affect the pH, the solution should be neutral.
2. If only the cation of the salt is acidic, the solution will be acidic.
3. If only the anion of the salt is basic, the solution will be basic.
4. If a salt has a cation that is acidic and an anion that is basic, the pH of the solution is determined by the *relative* strengths of the acid and base based on the K_a and K_b of the ions.

Let's consider two salts, sodium hypochlorite, NaOCl, and calcium nitrate, $Ca(NO_3)_2$, and see how we predict if their solutions will be acidic, basic, or neutral. We can write the equations for dissolving both salts as

$$NaOCl(s) \xrightarrow{H_2O} Na^+(aq) + OCl^-(aq)$$

$$Ca(NO_3)_2(s) \xrightarrow{H_2O} Ca^{2+}(aq) + 2NO_3^-(aq)$$

Now we consider whether or not each ion is related to a weak acid (for anions) or to a weak base (for cations). For the two anions, if we add a hydrogen ion to each, we can identify the acid that they are related to, HOCl and HNO_3. HNO_3 is one of our strong acids so the NO_3^- ion will not affect the pH of a solution. The HOCl on the other hand is a weak acid and will produce the conjugate base OCl^-. Turning our attention to the cations, we can see that the two cations are in Groups 1A and 2A, respectively, and are extremely weak acids that do not affect the pH of a solution. Finally, of all four ions, only the OCl^- will affect the pH. We identified the hypochlorite ion as a conjugate base and therefore its solution will be basic. Calcium nitrate solutions will be neutral since neither ion affects the pH. Neutral salts will have a pH of 7.00.

Figure 17.6 | **Acetate ion is a weak base in water.** The pH of a solution of $KC_2H_3O_2$ is greater than 7. Bromothymol blue has been added and has a blue color indicating a basic solution. *(Richard Megna/Fundamental Photographs.)*

■ The only time an anion might be acidic is if it is from a partially neutralized polyprotic acid—for example HSO_4^-.

Practice Exercises

17.25 | Are solutions of (a) $NaNO_2$, (b) KCl, and (c) NH_4Br acidic, basic, or neutral? (*Hint:* Write the ions for these compounds. What are the conjugate acids and bases of these ions?)

17.26 | Are solutions of (a) $NaNO_3$, (b) KOCl, and (c) NH_4NO_3 acidic, basic, or neutral?

Now that we have reinforced the concept that anions are conjugate bases and cations are conjugate acids, we can calculate the pH of their solutions. This will be done in exactly the same way in which we calculated the pH of solutions containing weak molecular acids or weak molecular bases.

Example 17.5

Calculating the pH of a Salt Solution

Household bleach used for washing clothes, and also mildew and moss from buildings and outdoor furniture, is a solution of sodium hypochlorite, NaOCl. What is the pH of a 0.10 *M* solution of NaOCl? For HOCl, $K_a = 3.0 \times 10^{-8}$.

Analysis: Problems such as this are just like the other acid–base equilibrium problems you have learned to solve. We proceed as follows: (1) We determine the nature of the solute: is it a weak acid, a weak base, or are both a weak acid and weak base present? (2) We write the appropriate chemical equation and equilibrium law. (3) We proceed with the solution.

Assembling the Tools: Since sodium is in Group 1A, that tells us that the Na^+ does not affect the pH. However the OCl^- is the conjugate base of the weak acid, HOCl. Therefore we have a solution of a weak base and we need to use K_b and the appropriate chemical reaction. The reaction we need describes how OCl^- reacts with water.

If you have trouble writing the correct chemical equation for this equilibrium, you should review Section 17.3.

$$OCl^- + H_2O \rightleftharpoons HOCl + OH^-$$

Then we write the appropriate equilibrium law as

$$K_b = \frac{[HOCl][OH^-]}{[OCl^-]}$$

We do not know the value of K_b for OCl^- but we do know that the K_a for HOCl is 3.0×10^{-8}. We will use the equation

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{3.0 \times 10^{-8}} = 3.3 \times 10^{-7}$$

to calculate the needed value for K_b. Now we can set up a concentration table to help us keep track of the numbers in our calculation.

Solution: We've written the balanced chemical equation above and also the equilibrium law, and we calculated K_b from the given value of K_a.

Now let's set up the concentration table. The only sources of HOCl and OH^- are the reaction of the OCl^-, so their concentrations will each increase by *x* and the concentration of OCl^- will decrease by *x*.

	H_2O + OCl^-	$\rightleftharpoons$	HOCl	+	OH^-
Initial concentrations (*M*)	0.10		0		0
Changes in concentrations (*M*)	$-x$		$+x$		$+x$
Equilibrium conc. (*M*)	$(0.10 - x) \approx 0.10$		x		x

At equilibrium, the concentrations of HOCl and OH^- are the same, *x*.

$$[HOCl] = [OH^-] = x$$

Because K_b is so small, $[\text{OCl}^-] \approx 0.10\ M$. (Once again, we expect x to be so small that we are able to use the initial concentration of the base as if it were the equilibrium concentration.) Substituting into the K_b expression gives

$$\frac{(x)(x)}{0.10 - x} \approx \frac{(x)(x)}{0.10} = 3.3 \times 10^{-7}$$

$$x = 1.8 \times 10^{-4}\ M$$

At this point we need to remember that the value of x represents the OH^- concentration, from which we can calculate the pOH and then the pH.

$$\begin{aligned}[\text{OH}^-] &= 1.8 \times 10^{-4}\ M \\ \text{pOH} &= -\log(1.8 \times 10^{-4}) = 3.74 \\ \text{pH} &= 14.00 - \text{pOH} \\ &= 14.00 - 3.74 \\ &= 10.26\end{aligned}$$

The pH of this solution is 10.26.

Is the Answer Reasonable? First, we check our assumption and find it is correct $(0.10 - 0.00018 = 0.10)$. Also, from the nature of the salt, we expect the solution to be basic. The calculated pH corresponds to a basic solution, so the answer seems to be reasonable. You've also seen that we can check the accuracy of the answer by substituting the calculated equilibrium concentrations into the mass action expression.

$$\frac{[\text{HOCl}][\text{OH}^-]}{[\text{OCl}^-]} = \frac{(x)(x)}{0.10} = \frac{(1.8 \times 10^{-4})^2}{0.10} = 3.2 \times 10^{-7}$$

The result is quite close to our value of K_b, so our answers are correct.

Practice Exercises

17.27 | What is the pH of a solution when 25.0 g of methylammonium chloride, $\text{CH}_3\text{NH}_3\text{Cl}$, is dissolved in enough water to make 500.0 mL of solution? (*Hint:* What is the molarity of the $\text{CH}_3\text{NH}_3\text{Cl}$ solution?)

17.28 | What is the pH of a 0.10 M solution of NaNO_2?

17.29 | 500.0 mL of a 0.20 M solution of ammonia is mixed with 500.0 mL of a 0.2 M solution of HBr. What is the pH of the resulting solution of NH_4Br?

Salts of a Weak Acid and a Weak Base

There are many salts whose ions are both able to affect the pH of the salt solution. Whether or not the salt has a net effect on the pH now depends on the relative strengths of both ions. If the cation and anion are identical in their respective strengths, the salt has no net effect on pH. In ammonium acetate, for example, the ammonium ion is an acidic cation and the acetate ion is a basic anion. However, the K_a of NH_4^+ is 5.6×10^{-10} and the K_b of $\text{C}_2\text{H}_3\text{O}_2^-$ just happen to be the same, 5.6×10^{-10}. The cation tends to produce H^+ ions to the same extent that the anion tends to produce OH^-. So in aqueous ammonium acetate, $[\text{H}^+] = [\text{OH}^-]$, and the solution has a pH of 7.

■ If *neither* the cation nor the anion is able to affect the pH, the salt solution will be neutral (provided no other acidic or basic solutes are present).

Now consider ammonium formate, NH_4CHO_2. The formate ion, CHO_2^-, is the conjugate base of the weak acid, formic acid, so it is a Brønsted base. Its K_b is 5.6×10^{-11}. Comparing this value to the (slightly larger) K_a of the ammonium ion, 5.6×10^{-10}, we see that NH_4^+ is slightly stronger as an acid than the formate ion is as a base. As a result, a solution of ammonium formate is slightly acidic. We are not concerned here about calculating a pH, only in predicting if the solution is acidic, basic, or neutral.

Practice Exercises

17.30 | Will an aqueous solution of ammonium cyanide, NH_4CN, be acidic, basic, or neutral? (*Hint:* These anions and cations are conjugates of an acid and a base listed in Tables 17.2 and 17.3.)

17.31 | Will an aqueous solution of ammonium nitrite, NH_4NO_2, be acidic, basic, or neutral?

17.7 | Buffer Solutions

Many chemical and biological systems are quite sensitive to pH. For example, if the pH of your blood were to change from what it should be, within the range of 7.35 to 7.42, either to 7.00 or to 8.00, you would die. Lakes and streams with a pH less than 5 often cannot support fish life. Thus, a change in pH can produce unwanted effects, and systems that are sensitive to pH must be protected from the H^+ or OH^- that might be formed or consumed by some reaction. *Buffers* are mixtures of solutes that accomplish this. Such a solution is said to be *buffered* or it is described as a *buffer solution.*

Composition of a Buffer

A **buffer** contains solutes that enable it to resist large changes in pH when small amounts of either strong acid or strong base are added to it. Ordinarily, the buffer consists of two solutes, one a weak Brønsted acid and the other its conjugate base. If the acid is molecular, then the conjugate base is *supplied by a soluble salt of the acid.* For example, a common buffer system consists of acetic acid plus sodium acetate, with the salt's acetate ion serving as the Brønsted base. In your blood, carbonic acid (H_2CO_3, a weak diprotic acid) and the bicarbonate ion (HCO_3^-, its conjugate base) serve as one of the buffer systems used to maintain a remarkably constant pH in the face of the body's production of organic acids by metabolism. Another common buffer consists of the weakly acidic cation, NH_4^+, supplied by a salt like NH_4Cl, and its conjugate base, NH_3.

One important point about buffers is the distinction between keeping a solution at a particular pH and keeping it neutral—at a pH of 7. Although it is certainly possible to buffer a solution at pH 7, buffers can be made that will work at any pH value throughout the pH scale.

How a Buffer Works

TOOLS

How buffers work

To work, a buffer must be able to neutralize either a strong acid or strong base that is added. This is precisely what the conjugate acid and base components of the buffer do. Consider, for example, a buffer composed of acetic acid, $HC_2H_3O_2$, and acetate ion, $C_2H_3O_2^-$, supplied by a salt such as $NaC_2H_3O_2$. If we add extra H^+ to the buffer (from a strong acid) the acetate ion (the weak conjugate base) can react with it as follows.

$$H^+(aq) + C_2H_3O_2^-(aq) \longrightarrow HC_2H_3O_2(aq)$$

■ Not all the added H^+ is neutralized, so the pH is lowered a little. Soon we'll see how much it changes.

Thus, the added H^+ changes some of the buffer's Brønsted base, $C_2H_3O_2^-$, to its conjugate (weak) acid, $HC_2H_3O_2$. This reaction prevents a large buildup of H^+ and a corresponding decrease in pH that would otherwise be caused by the addition of the strong acid.

A similar response occurs when a strong base is added to the buffer. The OH^- from the strong base will react with some $HC_2H_3O_2$.

$$HC_2H_3O_2(aq) + OH^-(aq) \longrightarrow C_2H_3O_2^-(aq) + H_2O$$

Here the added OH^- changes some of the buffer's Brønsted acid, $HC_2H_3O_2$, into its conjugate base, $C_2H_3O_2^-$. This prevents a buildup of OH^-, which would otherwise cause a large increase in the pH. Thus, one member of a buffer team neutralizes H^+ that might get into the solution, and the other member neutralizes OH^-. *Understanding buffers is an important tool for chemists to use in applications ranging from the protocols of a research project to designing a consumer product.*

Practice Exercises

17.32 | Acetic acid, $HC_2H_3O_2$, and sodium acetate, $NaC_2H_3O_2$ (this provides the acetate ion $C_2H_3O_2^-$), can be used to make an "acetate" buffer. Does the acetate ion or the acetic acid increase when a strong acid is added to the buffer? Is it the acetate ion or acetic acid that decreases when a strong base is added to the buffer? Explain your answers. (*Hint:* Which of the buffer components will react with HCl? Which will react with NaOH?)

17.33 | For a buffer composed of NH_3 and NH_4^+ (from NH_4Cl), write chemical equations that show what happens when (a) a small amount of strong acid is added, and (b) a small amount of strong base is added.

Calculating the pH of a Buffer Solution

Calculating the pH of a buffer mixture follows the same procedures we employed in Section 17.5 with a few small changes. The following example illustrates the principles involved.

Example 17.6

Calculating the pH of a Buffer

To study the effects of a weakly acidic medium on the rate of corrosion of a metal alloy, a student prepared a buffer solution containing both 0.110 *M* $NaC_2H_3O_2$ and 0.090 *M* $HC_2H_3O_2$. What is the pH of this solution?

■ **Analysis:** We recognize that this is a buffer solution because it contains *both* the weak acid $HC_2H_3O_2$ and its conjugate base $C_2H_3O_2^-$. Also, earlier we noted that when both solute species are present we can use *either* K_a or K_b to perform calculations, whichever is handy.

■ **Assembling the Tools:** In our tables we find $K_a = 1.8 \times 10^{-5}$ for $HC_2H_3O_2$, so the simplest approach is to use K_a and the corresponding balanced chemical equation for the ionization of the acid.

$$HC_2H_3O_2 \rightleftharpoons H^+ + C_2H_3O_2^- \qquad K_a = \frac{[H^+][C_2H_3O_2^-]}{[HC_2H_3O_2]} = 1.8 \times 10^{-5}$$

We will also be able to use the simplifying approximations developed earlier; these almost always work for buffers.

■ **Solution:** As usual, we begin with the chemical equation and the expression for K_a that we wrote above. Next, let's set up the concentration table so we can proceed logically. We will take the initial concentrations of $HC_2H_3O_2$ and $C_2H_3O_2^-$ to be the values given in the problem. There's no H^+ present from a strong acid, so we set this concentration equal to zero. If the initial concentration of H^+ is zero, its concentration must increase on the way to equilibrium, so under H^+ in the change row we enter $+x$. The other changes follow from that. For buffer solutions the quantity x will be very small, so it is safe to make the simplifying approximations in the last row. Here's the completed table.

	$HC_2H_3O_2$	$\rightleftharpoons$	H^+	+	$C_2H_3O_2^-$
Initial concentrations (*M*)	0.090		0		0.11
Changes in concentrations (*M*)	$-x$		$+x$		$+x$
Equilibrium concentrations (*M*)	$(0.090 - x)$		x		$(0.11 + x)$
	≈ 0.090				≈ 0.11

What remains, then, is to substitute the quantities from the last row of the table into the K_a expression.

$$\frac{(x)(0.11 + x)}{(0.090 - x)} \approx \frac{(x)(0.11)}{(0.090)} = 1.8 \times 10^{-5}$$

Solving for x gives us

$$x = \frac{(0.090) \times 1.8 \times 10^{-5}}{(0.11)} = 1.5 \times 10^{-5}$$

Because x equals $[H^+]$, we now have $[H^+] = 1.5 \times 10^{-5}$ M. Then we calculate pH:

$$\text{pH} = -\log(1.5 \times 10^{-5}) = 4.82$$

Thus, the pH of the buffer is 4.82.

■ Notice how small x is compared to the initial concentrations. The simplification was valid.

■ **Is the Answer Reasonable?** Again, we check our assumptions and find they worked ($0.090 - 0.000015 = 0.090$ and $0.11 + 0.000015 = 0.11$). Also, we can check the answer in the usual way by substituting our calculated equilibrium values into the mass action expression. Let's do it.

$$\frac{[H^+][C_2H_3O_2^-]}{[HC_2H_3O_2]} = \frac{(1.5 \times 10^{-5})(0.11)}{(0.090)} = 1.8 \times 10^{-5}$$

The reaction quotient equals K_a, so the values we've obtained are correct equilibrium concentrations.

Practice Exercises

17.34 | Calculate the pH of the buffer solution in the preceding example by using the K_b for $C_2H_3O_2^-$. Be sure to write the chemical equation for the equilibrium as the reaction of $C_2H_3O_2^-$ with water. Then use the chemical equation as a guide in setting up the equilibrium expression for K_b. (*Hint:* If you work the problem correctly, you should obtain the same answer as above.)

17.35 | One liter of buffer is made by dissolving 100.0 grams of acetic acid, $HC_2H_3O_2$, and 100.0 grams of sodium acetate, $NaC_2H_3O_2$, in enough water to make one liter. What is the pH of this solution?

The "Common Ion Effect"

If the solution in the preceding example had contained only acetic acid with a concentration of 0.090 M, the calculated $[H^+]$ would have been 1.3×10^{-3} M, considerably higher than that of the buffer, which also contains 0.11 M $C_2H_3O_2^-$. The effect of adding sodium acetate, a substance containing $C_2H_3O_2^-$ ion, to a solution of acetic acid is to suppress the ionization of the acid—it's an example of Le Châtelier's principle. Suppose, for example, we had established the equilibrium

$$HC_2H_3O_2 \rightleftharpoons H^+ + C_2H_3O_2^-$$

According to Le Châtelier's principle, if we add $C_2H_3O_2^-$, the reaction will proceed in a direction to remove some of it. This will shift the equilibrium to the left, thereby reducing the concentration of H^+.

In this example, acetate ion is said to be a **common ion,** in the sense that it is *common* to both the acetic acid equilibrium and to the salt we added, sodium acetate. The suppression of the ionization of acetic acid by addition of the common ion is referred to as the **common ion effect.** We will encounter this phenomenon again in Chapter 18 when we consider the solubilities of salts.

Simplifications in Buffer Calculations

There are two useful simplifications that we can use in working buffer calculations. The first is the one we made in Example 17.3:

> Because the initial concentrations are so close to the equilibrium concentrations in the buffer mixture, we can use *initial* concentrations of both the weak acid and its conjugate base as though they were equilibrium values.

■ There are some buffer systems for which these simplifications might not work. However, you will not encounter them in this text.

A further simplification can be made because the mass action expression contains the ratio of the molar concentrations (in units of moles per liter) of the acid and conjugate base. Let's enter these units for the acid and its conjugate base into the mass action expression. For an acid H*A*,

$$K_a = \frac{[\mathrm{H}^+][A^-]}{[\mathrm{H}A]} = \frac{[\mathrm{H}^+](\mathrm{mol}\,A^-\ \cancel{\mathrm{L}^{-1}})}{(\mathrm{mol\ H}A\ \ \cancel{\mathrm{L}^{-1}})} = \frac{[\mathrm{H}^+](\mathrm{mol}\,A^-)}{(\mathrm{mol\ H}A)} \qquad \textbf{(17.16)}$$

Notice that the units L^{-1} cancel from the numerator and denominator. This means that for a given acid–base pair, $[\mathrm{H}^+]$ is determined by the *mole* ratio of conjugate base to conjugate acid; we don't *have* to use molar concentrations.

> *For buffer solutions* ***only,*** we can use either molar concentrations or moles in the K_a (or K_b) expression to express the amounts of the acid and its conjugate base. However, *we must use the same units for each member of the pair.*

A further consequence of the relationship derived in Equation 17.16 is that the pH of a buffer should not change if the buffer is diluted. Dilution changes the volume of a solution but it does not change the number of moles of the solutes, so their mole *ratio* remains constant and so does $[\mathrm{H}^+]$.

Preparing Buffers with a Desired pH

The hydrogen ion concentration of a buffer is controlled by both K_a and the ratio of concentrations (or ratio of moles) of the members of the acid–base pair. This can be seen by rearranging Equation 17.16 to solve for $[\mathrm{H}^+]$:

$$[\mathrm{H}^+] = K_a \frac{[\mathrm{H}A]}{[A^-]} \qquad \textbf{(17.17)}$$

or

$$[\mathrm{H}^+] = K_a \frac{\mathrm{mol\ H}A}{\mathrm{mol}\,A^-} \qquad \textbf{(17.18)}$$

Solutions of conjugate acid–base pairs will generally act as buffers when the mole (or molarity) ratio of acid to base is between 0.1 and 10. When this ratio is less than 0.1, added base will cause large pH changes. When the ratio is greater than 10, small additions of acid will cause large pH changes. When the ratio is close to 1.0, the solution will be effective if either strong acid or strong base is added. Therefore, if we want to prepare a buffer that works well near some specified pH, we look for an acid with a K_a as close to the desired pH as possible. A high concentration of both the conjugate acid and base will increase the buffer's ability to resist pH change. This is called the **buffer capacity,** and it is equal to the moles of strong acid, or strong base, needed to change the pH of one liter of buffer by 1.0 pH unit. For experiments in biology, the toxicity of the members of the acid–base pair must also be considered, and that often narrows the choices considerably.

Example 17.7
Preparing a Buffer Solution to Have a Predetermined pH

A solution buffered at a pH of 5.00 is needed in an experiment. Can we use acetic acid and sodium acetate to make it? If so, what is the mole ratio of acetic acid and sodium acetate that will result in a pH = 5.00 solution? How many moles of $NaC_2H_3O_2$ must be added to 1.0 L of a solution that contains 1.0 mol $HC_2H_3O_2$ to prepare the buffer?

■ **Analysis:** We need to do three things in this problem. First, we need to decide if, in fact, acetic acid can be used for a pH = 5.00 buffer. Second, we need to use the appropriate equations to determine the mole ratio and then, third, the amount of sodium acetate to use.

■ **Assembling the Tools:** The first tool describes the necessary relationship between pK_a and pH to successfully prepare a buffer solution:

$$\text{pH} = \text{p}K_a \pm 1$$

If we only have the K_a we also need Equation 17.6 to calculate the pK_a. Next we need the equations to convert pH to $[H^+]$ and then use it to solve Equation 17.16 to calculate the necessary mole ratio. Once we have this, we can proceed to calculate the number of moles of $C_2H_3O_2^-$ needed, and then the number of moles of $NaC_2H_3O_2$.

■ **Solution:** Looking up the K_a for acetic acid we find it is 1.8×10^{-5}. Because we want the pH to be 5.00, the pK_a of the selected acid should be 5.00 ± 1. We use Equation 17.6 to calculate the pK_a.

$$\text{p}K_a = -\log(1.8 \times 10^{-5}) = 4.74$$

From this we determine that acetic acid *is appropriate* for this buffer.

Next, we use Equation 17.16 to find the mole ratio of solutes.

$$[H^+] = K_a \times \frac{(\text{mol } HC_2H_3O_2)}{(\text{mol } C_2H_3O_2^-)}$$

First, let's solve for the mole ratio.

$$\frac{(\text{mol } HC_2H_3O_2)}{(\text{mol } C_2H_3O_2^-)} = \frac{[H^+]}{K_a}$$

The desired pH = 5.00, so $[H^+] = 1.0 \times 10^{-5}$; also $K_a = 1.8 \times 10^{-5}$. Substituting gives

$$\frac{(\text{mol } HC_2H_3O_2)}{(\text{mol } C_2H_3O_2^-)} = \frac{1.0 \times 10^{-5}}{1.8 \times 10^{-5}} = 0.56$$

This is the *mole* ratio of the buffer components that is needed.

For the final step, the solution we are preparing contains 1.0 mol $HC_2H_3O_2$, so the number of moles of acetate ion required is

$$\begin{aligned} \text{moles } C_2H_3O_2^- &= \frac{1.0 \text{ mol } HC_2H_3O_2}{0.56} \\ &= 1.8 \text{ mol } C_2H_3O_2^- \end{aligned}$$

For each mole of $NaC_2H_3O_2$ there is one mole of $C_2H_3O_2^-$, so to prepare the solution we need 1.8 mol $NaC_2H_3O_2$.

■ **Are the Answers Reasonable?** A 1-to-1 mole ratio of $C_2H_3O_2^-$ to $HC_2H_3O_2$ would give pH = pK_a = 4.74. The desired pH of 5.00 is slightly more basic than 4.74, so can expect that the amount of conjugate base needed should be larger than the amount of conjugate acid. Our answer of 1.8 mol of $NaC_2H_3O_2$ appears to be reasonable.

Practice Exercises

17.36 | From Table 17.2 select an acid that, along with its sodium salt, can be used to make a buffer that has a pH of 5.25. If you have 500.0 mL of a 0.200 *M* solution of that acid, how many grams of the corresponding sodium salt do you have to dissolve to obtain the desired pH? (*Hint:* There is more than one correct answer to this problem. The first step is to determine the ratio of molarities of the conjugate acid and conjugate base.)

17.37 | A chemist needed an aqueous buffer with a pH of 3.90. Would formic acid and its salt, sodium formate, make a good pair for this purpose? If so, what mole ratio of the acid, $HCHO_2$, to the anion of this salt, CHO_2^-, is needed? How many grams of $NaCHO_2$ would have to be added to a solution that contains 0.10 mol $HCHO_2$?

If you take a biology course, you're likely to run into a logarithmic form of Equation 17.9 called the **Henderson–Hasselbalch equation**. This is obtained by taking the negative logarithm of both sides of Equation 17.9 and rearranging to get

$$\text{pH} = \text{p}K_a + \log\frac{[A^-]}{[HA]} \qquad \textbf{(17.19)}$$

In most buffers used in the life sciences, the anion A^- comes from a salt in which the cation has a charge of 1+, such as Na*A*, and the acid is monoprotic. With these as conditions, the equation is sometimes written

$$\text{pH} = \text{p}K_a + \log\frac{[\text{salt}]}{[\text{acid}]} \qquad \textbf{(17.20)}$$

For practice, you may wish to apply this equation to buffer problems at the end of the chapter.

Calculating pH Change for a Buffer

Earlier we described how a buffer is able to neutralize small amounts of either strong acid or base to keep the pH from changing by large amounts. We can use this knowledge now to calculate how much the pH will change.

Example 17.8

Calculating How a Buffer Resists Changes in pH

How much will the pH change if 0.020 mol of HCl is added to a buffer solution that was made by dissolving 0.12 mol of NH_3 and 0.095 mol of NH_4Cl in 250 mL of water?

■ **Analysis:** This problem will require two calculations. The first is to determine the pH of the original buffer. The second is to determine the pH of the mixture after the HCl has been added. For the second calculation, we have to determine how the acid changes the amounts of NH_3 and NH_4^+.

■ **Assembling the Tools:** For the pH of the initial solution we need the chemical reaction and the K_b for NH_3.

$$NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^- \qquad K_b = \frac{[NH_4^+][OH^-]}{[NH_3]} = 1.8 \times 10^{-5}$$

To determine the pH of the solution after the HCl was added we need the chemical reaction for HCl in this mixture. Since HCl is a strong acid, it will react quantitatively (completely) with the conjugate base of the buffer—in this case, NH_3. The balanced molecular equation is

$$NH_3 + HCl \longrightarrow NH_4Cl$$

In this case it is better to write the net ionic equation as

$$NH_3 + H^+ \longrightarrow NH_4^+$$

We then do a limiting reactant calculation to determine how much of the NH_3 will be converted to NH_4^+. We then use the new amounts of NH_3 and NH_4^+ to determine the pH.

Solution: We begin by calculating the pH of the buffer before the HCl is added. The solution contains 0.12 mol of NH_3 and 0.095 mol of NH_4^+ from the complete dissociation of the salt NH_4Cl. We can enter these quantities into the mass action expression in place of concentrations and solve for $[OH^-]$. As noted earlier, we can use moles of NH_3 and NH_4^+ in place of molarities to solve buffer problems.

The solution also contains 0.095 mol of Cl^-, of course, but this ion is not involved in the equilibrium.

$$1.8 \times 10^{-5} = \frac{(\text{mol } NH_4^+) \times [OH^-]}{(\text{mol } NH_3)} = \frac{(0.095)[OH^-]}{(0.12)}$$

solving for $[OH^-]$ gives

$$[OH^-] = 2.3 \times 10^{-5}$$

To calculate the pH, we obtain pOH and subtract it from 14.00.

$$\text{pOH} = -\log (2.3 \times 10^{-5}) = 4.64$$
$$\text{pH} = 14.00 - 4.64 = 9.36$$

This is the pH before we add any HCl.

Next, we consider the reaction that takes place when we add the HCl to the buffer. The 0.020 mol of HCl is completely ionized, so we're adding 0.020 mol H^+. The 0.020 mol of acid will react with 0.020 mol of NH_3 to form 0.020 mol of NH_4^+. This causes the number of moles of NH_3 to *decrease* by 0.020 mol and the number of moles of NH_4^+ to *increase* by 0.020 mol. After addition of the acid, we have

The equilibrium constant for this reaction is 1.8×10^{10}, so the reaction goes almost to completion. Nearly all the added H^+ reacts with NH_3.

Number of moles in the original buffer mixture

Change in the number of moles because of reaction

$$\text{moles of } NH_3 = 0.12 \text{ mol} - 0.020 \text{ mol} = 0.10 \text{ mol } NH_3$$

$$\text{moles of } NH_4^+ = 0.095 \text{ mol} + 0.020 \text{ mol} = 0.115 \text{ mol } NH_4^+$$

We now use these new amounts of NH_3 and NH_4^+ to calculate the new pH of the buffer solution. First, we calculate $[OH^-]$.

$$1.8 \times 10^{-5} = \frac{(\text{mol } NH_4^+) \times [OH^-]}{(\text{mol } NH_3)} = \frac{(0.115)[OH^-]}{(0.10)}$$

Solving for $[OH^-]$ gives

$$[OH^-] = 1.6 \times 10^{-5}$$

To calculate the pH, we obtain pOH and subtract it from 14.00.

$$\text{pOH} = -\log (1.6 \times 10^{-5}) = 4.80$$
$$\text{pH} = 14.00 - 4.80 = 9.20$$

This is the pH after addition of the acid. We're asked for the change in pH, so we take the difference between the two values:

$$\text{change in pH} = 9.20 - 9.36 = -0.16$$

Thus, the pH has decreased by 0.16 pH units.

Is the Answer Reasonable? In general, we can assume that changes in pH should be small (less than 1.0 pH unit), otherwise there's no simple way to estimate how *much* the pH will change when H^+ or OH^- is added to the buffer. However, we can anticipate the *direction* of the change. Adding H^+ to a buffer will lower the pH somewhat and adding OH^- will raise it. In this example, the buffer is absorbing H^+, so its pH should decrease, and our calculations agree. If our calculated pH had been higher than the original, we might expect to find errors in the calculation of the final values for the number of moles of NH_3 and NH_4^+.

Practice Exercises

17.38 | How much will the pH change if we add 0.15 mol NaOH to 1.00 L of a buffer that contains 1.00 mol $HC_2H_3O_2$ and 1.00 mol $NaC_2H_3O_2$? (*Hint:* Will the NaOH react with $HC_2H_3O_2$ or $NaC_2H_3O_2$? Write the equation for the reaction.)

17.39 | A buffer is prepared by mixing 50.0 g of NH_3 and 50.0 g of NH_4Cl in 0.500 L of solution. What is the pH of this buffer, and what will the pH change to if 5.00 g of HCl is then added to the mixture?

If you look back over the calculations in the preceding example, you can get some feel for how effective buffers can be at preventing large swings in pH. Notice that we've added enough HCl to react with approximately 20% of the NH_3 in the solution, but the pH changed by only 0.16 pH units. If we were to add this same amount of HCl to 0.250 L of pure water, it would give a solution with $[H^+] = 0.080\ M$. Such a solution would have a pH of 1.10, which is quite acidic. However, the buffer mixture stayed basic, with a pH of 9.20, even after addition of the acid. That's pretty remarkable!

17.8 | Polyprotic Acids

Until now our discussion of weak acids has focused entirely on equilibria involving monoprotic acids. There are, of course, many acids capable of supplying more than one H^+ per molecule. Recall that these are called polyprotic acids. Examples include sulfuric acid, H_2SO_4, carbonic acid, H_2CO_3, and phosphoric acid, H_3PO_4. These acids undergo ionization in a series of steps, each of which releases one proton. For weak polyprotic acids, such as H_2CO_3 and H_3PO_4, each step is an equilibrium. Even sulfuric acid, which we consider a strong acid, is not completely ionized. Loss of the first proton to yield the HSO_4^- ion is complete, but the loss of the second proton is incomplete and involves an equilibrium. In this section, we will focus our attention on weak polyprotic acids as well as solutions of their salts.

Let's begin with the weak diprotic acid, H_2CO_3. In water, the acid ionizes in two steps, each of which is an equilibrium that transfers an H^+ ion to a water molecule.

$$H_2CO_3 + H_2O \rightleftharpoons H_3O^+ + HCO_3^-$$

$$HCO_3^- + H_2O \rightleftharpoons H_3O^+ + CO_3^{2-}$$

As usual, we can use H^+ in place of H_3O^+ and simplify these equations to give

$$H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$$

$$HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}$$

Each step has its own ionization constant, K_a, which we identify as K_{a_1} for the first step and K_{a_2} for the second. For carbonic acid,

$$K_{a_1} = \frac{[H^+][HCO_3^-]}{[H_2CO_3]} = 4.3 \times 10^{-7}$$

$$K_{a_2} = \frac{[H^+][CO_3^{2-}]}{[HCO_3^-]} = 5.6 \times 10^{-11}$$

Notice that each ionization makes a contribution to the total molar concentration of H^+, and one of our goals here is to relate the K_a values and the concentration of the acid

Vitamin C. Many fruits and vegetables contain ascorbic acid (vitamin C), a weak diprotic acid with the formula $H_2C_6H_6O_6$. *(Andy Washnik)*

TOOLS

Polyprotic acids ionize stepwise

to [H^+]. At first glance, this seems to be a formidable task, but certain simplifications are justified that make the problem relatively simple to solve.

Simplifications in Calculations

The principal factor that simplifies calculations involving many polyprotic acids is the large differences between successive ionization constants. Notice that for H_2CO_3, K_{a_1} is much larger than K_{a_2} (they differ by a factor of nearly 10,000). Similar differences between K_{a_1} and K_{a_2} are observed for many diprotic acids. One reason is that an H^+ is lost much more easily from the neutral H_2A molecule than from the HA^- ion. The stronger attraction of the opposite charges inhibits the second ionization. Typically, K_{a_1} is greater than K_{a_2} by a factor of between 10^4 and 10^5, as the data in Table 17.4 show. For a triprotic acid, such as phosphoric acid, H_3PO_4, the second acid ionization constant is similarly greater than the third.

■ Additional K_a values of polyprotic acids are located in Appendix C–7.

Because K_{a_1} is so much larger than K_{a_2}, at equilibrium virtually all the H^+ in a solution of the acid comes from the first step in the ionization. In other words,

$$[H^+]_{\text{equilib}} = [H^+]_{\text{first step}} + [H^+]_{\text{second step}}$$

$$[H^+]_{\text{first step}} \gg [H^+]_{\text{second step}}$$

Therefore, we make the approximation that

$$[H^+]_{\text{equilib}} \approx [H^+]_{\text{first step}}$$

This means that as far as calculating the H^+ concentration is concerned, we can treat the acid as though it were a monoprotic acid and ignore the second step in the ionization. In addition we have

$$[HCO_3^-]_{\text{equilib}} = [HCO_3^-]_{\text{first step}} - [CO_3^{2-}]_{\text{second step}}$$

However, since $[CO_3^{2-}]_{\text{second step}} = [H^+]_{\text{second step}}$ and $[H^+]_{\text{second step}}$ is very small we can say that

$$[HCO_3^-]_{\text{equilib}} \approx [HCO_3^-]_{\text{first step}}$$

Table 17.4 Acid Ionization Constants for Polyprotic Acids

		Acid Ionization Constant for Successive Ionizations (25 °C)		
Name	**Formula**	**1st**	**2nd**	**3rd**
Carbonic acid	H_2CO_3	4.3×10^{-7}	5.6×10^{-11}	
Hydrosulfuric acid	H_2S (*aq*)	8.9×10^{-8}	1×10^{-19}	
Phosphoric acid	H_3PO_4	7.5×10^{-3}	6.2×10^{-8}	4.2×10^{-13}
Arsenic acid	H_3AsO_4	5.5×10^{-3}	1.7×10^{-7}	5.1×10^{-12}
Sulfuric acid	H_2SO_4	Large	1.2×10^{-2}	
Selenic acid	H_2SeO_4	Large	1.2×10^{-2}	
Telluric acid	H_6TeO_6	2×10^{-8}	1×10^{-11}	
Sulfurous acid	H_2SO_3	1.2×10^{-2}	6.6×10^{-8}	
Selenous acid	H_2SeO_3	4.5×10^{-3}	5×10^{-8}	
Tellurous acid	H_2TeO_3	3.3×10^{-3}	2.0×10^{-8}	
Ascorbic acid (vitamin C)	$H_2C_6H_6O_6$	8.0×10^{-5}	1.6×10^{-12}	
Oxalic acid	$H_2C_2O_4$	6.0×10^{-2}	6.1×10^{-5}	
Citric acid (18 °C)	$H_3C_6H_5O_7$	7.1×10^{-4}	1.7×10^{-5}	6.3×10^{-6}

It is therefore reasonable to conclude that

$$[\mathrm{H}^+]_{\mathrm{equilib}} = [\mathrm{HCO_3}^-]_{\mathrm{equilib}}$$

This last equality leads to the interesting result

$$K_{\mathrm{a}_2} = \frac{[\mathrm{H}^+][\mathrm{CO_3}^{2-}]}{[\mathrm{HCO_3}^-]} = 5.6 \times 10^{-11} = [\mathrm{CO_3}^{2-}]$$

meaning the molar concentration of the carbonate ion is simply K_{a_2} when the only solute is carbonic acid. This will be true for other diprotic acids that have widely different K_{a_1} and K_{a_2} values.

Example 17.9 illustrates how these relationships are applied.

Example 17.9

Calculating the Concentrations of Solute Species in a Solution of a Polyprotic Acid

Calculate the concentrations of all the species in a solution of 0.040 *M* $\mathrm{H_2CO_3}$ as well as the pH of the solution.

■ **Analysis:** We will use the procedures developed above to determine $[\mathrm{H}^+]$, pH, $[\mathrm{H_2CO_3}]$, $[\mathrm{HCO_3}^-]$, and $[\mathrm{CO_3}^{2-}]$.

■ **Assembling the Tools:** As in any equilibrium problem, we begin with the chemical equations and the K_a expressions

$$\mathrm{H_2CO_3} \rightleftharpoons \mathrm{H}^+ + \mathrm{HCO_3}^- \qquad K_{\mathrm{a}_1} = \frac{[\mathrm{H}^+][\mathrm{CO_3}^-]}{[\mathrm{H_2CO_3}]} = 4.3 \times 10^{-7}$$

$$\mathrm{HCO_3}^- \rightleftharpoons \mathrm{H}^+ + \mathrm{CO_3}^{2-} \qquad K_{\mathrm{a}_2} = \frac{[\mathrm{H}^+][\mathrm{CO_3}^{2-}]}{[\mathrm{HCO_3}^-]} = 5.6 \times 10^{-11}$$

Once we have these equations, it is a matter of applying them, with our chemical insights, in the appropriate manner. The two approximations that will be very useful are

$$[\mathrm{H}^+]_{\mathrm{equilib}} \approx [\mathrm{H}^+]_{\text{first step}}$$

and

$$[\mathrm{HCO_3}^-]_{\mathrm{equilib}} \approx [\mathrm{HCO_3}^-]_{\text{formed in first step}}$$

■ **Solution:** Treating $\mathrm{H_2CO_3}$ as though it were a monoprotic acid yields a problem similar to Example 17.3. We know some of the $\mathrm{H_2CO_3}$ ionizes; let's call this amount *x*. If *x* moles per liter of $\mathrm{H_2CO_3}$ ionizes, then *x* moles per liter of H^+ and $\mathrm{HCO_3}^-$ are formed, and the concentration of $\mathrm{H_2CO_3}$ is reduced by *x*.

	$\mathrm{H_2CO_3}$	$\rightleftharpoons$	H^+	$+$	$\mathrm{HCO_3}^-$
Initial concentrations (*M*)	0.040		0		0
Changes in concentrations (*M*)	$-x$		$+x$		$+x$
Equilibrium concentrations (*M*)	$(0.040 - x) \approx 0.040$		x		x

Substituting into the expression for K_{a_1} gives

$$\frac{x^2}{(0.040 - x)} \approx \frac{x^2}{0.040} = 4.3 \times 10^{-7}$$

Solving for *x* gives $x = 1.3 \times 10^{-4}$, so $[\mathrm{H}^+] = [\mathrm{HCO_3}^-] = 1.3 \times 10^{-4}$ *M*. Notice that our simplifying assumption is true and $[\mathrm{H_2CO_3}]$ remains at 0.040 *M*. From this we can now calculate the pH.

$$\mathrm{pH} = -\log\,(1.3 \times 10^{-4}) = 3.89$$

Now let's calculate the concentration of CO_3^{2-}. We obtain this from the expression for K_{a_2}.

$$K_{a_2} = \frac{[H^+][CO_3^{2-}]}{[HCO_3^-]} = 5.6 \times 10^{-11}$$

In our analysis, we concluded that we can use the approximations

$$[H^+]_{\text{equilib}} \approx [H^+]_{\text{first step}}$$
$$[HCO_3^-]_{\text{equilib}} \approx [HCO_3^-]_{\text{first step}}$$

■ Keep in mind that for a given solution, the values of H^+ used in the expressions for K_{a_1} and K_{a_2} are identical. At equilibrium there is only *one* equilibrium H^+ concentration.

Substituting the values obtained above gives us

$$\frac{(\cancel{1.3 \times 10^{-4}})[CO_3^{2-}]}{\cancel{1.3 \times 10^{-4}}} = 5.6 \times 10^{-11}$$

$$[CO_3^{2-}] = 5.6 \times 10^{-11} = K_{a_2}$$

Let's summarize the results. At equilibrium, we have

$$[H_2CO_3] = 0.040\ M$$
$$[H^+] = [HCO_3^-] = 1.3 \times 10^{-4}\ M \text{ and pH} = 3.89$$
$$[CO_3^{2-}] = 5.6 \times 10^{-11}\ M$$

■ **Are the Answers Reasonable?** To start, we check our assumptions. First, the initial concentration was assumed to be much larger than the hydrogen ion concentration, and it is $(0.040 - 0.00013 = 0.040)$. The second approximation was that the amount of CO_3^{2-} formed would be very small in relation to the HCO_3^- (and also H^+) concentration calculated in the first step. This assumption is true too $(1.3 \times 10^{-4} - 5.6 \times 10^{-11} = 1.3 \times 10^{-4})$. We can also check that the hydrogen ions added in the second step are inconsequential $(1.3 \times 10^{-4} + 5.6 \times 10^{-11} = 1.3 \times 10^{-4})$.

We've checked our assumptions and they are okay. The pH is less than 7; this is what we expect from an acid. If more verification is needed, you can always perform a quick check of the answers by substituting them into the appropriate mass action expressions:

$$\frac{(1.3 \times 10^{-4})(1.3 \times 10^{-4})}{0.040} = 4.2 \times 10^{-7}, \quad \text{which is very close to } K_{a_1}$$

$$\frac{(1.3 \times 10^{-4})(4.7 \times 10^{-11})}{(1.3 \times 10^{-4})} = 5.6 \times 10^{-11}, \quad \text{which equals } K_{a_2}$$

One last thing: the problem asked for *all species* in this solution of H_2CO_3. Two other substances are in the reaction mixture, water and hydroxide ions and a rigorous solution would also include these species.

Practice Exercises

17.40 | Write the three ionization steps for phosphoric acid, H_3PO_4, and write the K_a expressions for each step. (*Hint:* Recall that one proton is ionized in each step.)

17.41 | Ascorbic acid (vitamin C) is a diprotic acid, $H_2C_6H_6O_6$. (See Table 17.4.) Calculate $[H^+]$, pH, and $[C_6H_6O_6^{2-}]$ in a 0.10 M solution of ascorbic acid.

One of the most interesting observations we can derive from the preceding example is that *in a solution that contains a polyprotic acid* ***as the only solute,*** *the concentration of the ion formed in the second step of the ionization equals* K_{a_2}.

Salts of Polyprotic Acids

You learned earlier that the pH of a salt solution is controlled by whether the salt's cation, anion, or both are able to react with water. For simplicity, the salts of polyprotic acids that we will discuss here will be limited to those containing *nonacidic* cations, such as sodium or potassium ion. In other words, we will study salts in which the anion alone is basic and thereby affects the pH of a solution.

A typical example of a salt of a polyprotic acid is sodium carbonate, Na_2CO_3. It is a salt of H_2CO_3, and the salt's carbonate ion is a Brønsted base that is responsible for *two* equilibria that furnish OH^- ion and thereby affect the pH of the solution. These equilibria and their corresponding expressions for K_b are as follows:

$$CO_3^{2-}(aq) + H_2O \rightleftharpoons HCO_3^-(aq) + OH^-(aq) \qquad \textbf{(17.21)}$$

$$K_{b_1} = \frac{[HCO_3^-][OH^-]}{[CO_3^{2-}]}$$

$$HCO_3^-(aq) + H_2O \rightleftharpoons H_2CO_3(aq) + OH^-(aq) \qquad \textbf{(17.22)}$$

$$K_{b_2} = \frac{[H_2CO_3][OH^-]}{[HCO_3^-]}$$

The calculations required to determine the concentrations of the species involved in these equilibria are very much like those involving weak diprotic acids. The difference is that the chemical reactions here are those of bases instead of acids. In fact, *the simplifying assumptions in our calculations will be almost identical to those for weak polyprotic acids.*

First, let's determine the value of K_{b_1} and K_{b_2} for the successive equilibria in Equations 17.21 and 17.22. To obtain these constants, we will use the relationship that $K_a \times K_b = K_w$ along with the tabulated values of K_{a_1} and K_{a_2} for H_2CO_3.

At the start of this section we saw that $HCO_3^-(aq)$ and $CO_3^{2-}(aq)$ are associated with K_{a_2}. When a salt containing CO_3^{2-} reacts with water, the CO_3^{2-} is the base (Equation 17.21), the conjugate acid is HCO_3^-. Therefore, K_{b_1} contains the same conjugate acid–base pair as K_{a_2}. Therefore we calculate K_{b_1} from K_{a_2} as

$$K_{b_1} = \frac{K_w}{K_{a_2}} = \frac{1.0 \times 10^{-14}}{5.6 \times 10^{-11}} = 1.8 \times 10^{-4}$$

Similarly, we see that $H_2CO_3(aq)$ and $HCO_3^-(aq)$ are associated with K_{a_1}. When HCO_3^- is the base (Equation 17.22), the conjugate acid is H_2CO_3. Therefore, to calculate K_{b_2} we must use K_{a_1} because both have the same conjugate acid–base pair in the equilibrium expression

$$K_{b_2} = \frac{K_w}{K_{a_1}} = \frac{1.0 \times 10^{-14}}{4.3 \times 10^{-7}} = 2.3 \times 10^{-8}$$

Now we can compare the two K_b values. For CO_3^{2-}, $K_{b_1} = 1.8 \times 10^{-4}$, and for the (much) weaker base, HCO_3^-, K_{b_2} is 2.3×10^{-8}. Thus CO_3^{2-} has a K_b nearly 10,000 times that of HCO_3^-. This means that the reaction of CO_3^{2-} with water (Equation 17.21) generates far more OH^- than the reaction of HCO_3^- (Equation 17.22). The contribution of the latter to the total pool of OH^- is relatively so small that we can safely ignore it. The simplification here is very much the same as in our treatment of the ionization of weak polyprotic acids.

$$[OH^-]_{\text{equilib}} = [OH^-]_{\text{formed in first step}} + [OH^-]_{\text{formed in second step}}$$

$$[OH^-]_{\text{formed in first step}} \gg [OH^-]_{\text{formed in second step}}$$

$$[OH^-]_{\text{equilib}} \approx [OH^-]_{\text{formed in first step}}$$

Thus, if we wish to calculate the pH of a solution of a basic anion of a polyprotic acid, *we may work exclusively with K_{b_1} and ignore any further reactions.* Let's study an example of how this works.

SAVOGRAN
TSP
Trisodium Phosphate
All-purpose
Heavy duty cleaner

The salt Na_3PO_4 is sold under the name trisodium phosphate or TSP. Solutions of the salt in water are quite basic and are used as an aid in cleaning grime from painted surfaces. Some states restrict the sale of TSP because the phosphate ion it contains presents a pollution problem by promoting the growth of algae in lakes. *(© 1999 Richard Megna/Fundamental Photographs)*

■ In general, K_b values for anions of polyprotic acids are not tabulated. When needed, they are calculated from the appropriate K_a values for the acids.

■ Remember: K_{b_1} comes from K_{a_2}, and K_{b_2} comes from K_{a_1}.

Example 17.10
Calculating the pH of a Solution of a Salt of a Weak Diprotic Acid

Some detergents that use sodium carbonate as their caustic ingredient. Detergents are best able to dissolve grease and grime if their solutions are basic. In these products, the basic ingredient is sodium carbonate. The salt Na_2CO_3 is relatively nontoxic and the carbonate ion it contains is a relatively strong base. The carbonate ion also serves as a water softener by precipitating Ca^{2+} ions as insoluble $CaCO_3$. *(Paul Silverman/Fundamental Photographs)*

What is the pH of a 0.11 *M* solution of Na_2CO_3?

Analysis: Based on the discussion above we will approach this question in the same way that we solved Example 17.5 previously for a salt of a monoprotic acid.

Assembling the Tools: We can ignore the reaction of HCO_3^- with water, so the only relevant equilibrium is

$$CO_3^{2-} + H_2O \rightleftharpoons HCO_3^- + OH^- \qquad K_{b_1} = \frac{[HCO_3^-][OH^-]}{[CO_3^{2-}]} = 1.8 \times 10^{-4}$$

(The value of K_{b_1} was calculated from K_{a_2} in the discussion preceding this example.)

Solution: Some of the CO_3^{2-} will react; we'll let this be x mol L^{-1}. The concentration table, with our simplifying assumption, is as follows.

	H_2O	+	CO_3^{2-}	$\rightleftharpoons$	HCO_3^-	+	OH^-
Initial concentrations (*M*)			0.11		0		0
Changes in concentrations (*M*)			$-x$		$+x$		$+x$
Equilibrium concentrations (*M*)			$(0.11 - x) \approx 0.11$		x		x

Now we're ready to insert the values in the last row of the table into the equilibrium expression for the carbonate ion.

$$\frac{[HCO_3^-][OH^-]}{[CO_3^{2-}]} = \frac{(x)(x)}{0.11 - x} \approx \frac{(x)(x)}{0.11} = 1.8 \times 10^{-4}$$

$$x = [OH^-] = 4.4 \times 10^{-3} \text{ mol L}^{-1}$$

and

$$\text{pOH} = -\log(4.4 \times 10^{-3}) = 2.36$$

Finally, we calculate the pH by subtracting pOH from 14.00.

$$\text{pH} = 14.00 - 2.36 = 11.64$$

Thus, the pH of 0.11 *M* Na_2CO_3 is calculated to be 11.64. Once again we see that an aqueous solution of a salt composed of a basic anion and a neutral cation is basic.

Is the Answer Reasonable? Our result was reasonable since our assumption was true: $(0.11 - 0.0048 = 0.11)$ when properly rounded. Also, the pH we obtained corresponds to a basic solution, which is what we expect when the anion of the salt reacts as a weak base. The answer seems reasonable.

Practice Exercises

17.42 | Sodium bicarbonate gives solutions that are slightly alkaline (approximately pH 8.3), and similar solutions of sodium hydroxide (lye) are very basic with a pH around 12 or more. Lye will cause major damage, if not death, if swallowed, while sodium bicarbonate is a common antacid. Calculate the pH of a 0.10 *M* sodium carbonate solution and decide if it is an acceptable substitute for sodium bicarbonate. (*Hint:* The conjugate base in this problem is the carbonate ion.)

17.43 | What is the pH of a 0.20 *M* solution of Na_2SO_3 at 25 °C? For the diprotic acid, H_2SO_3, $K_{a_1} = 1.2 \times 10^{-2}$ and $K_{a_2} = 6.6 \times 10^{-8}$.

17.44 | Reasoning by analogy from what you learned about solutions of weak polyprotic acids, what is the molar concentration of H_2SO_3 in a 0.010 *M* solution of Na_2SO_3?

17.9 | Acid–Base Titrations

In Chapter 5 we studied the overall procedure for an acid–base titration, and we saw how titration data can be used in various stoichiometric calculations. In performing this procedure, the titration is halted at the **end point** when a change in color of an **indicator** occurs. Ideally, this end point should coincide with the theoretical **equivalence point,** where the calculated, stoichiometrically equivalent, amounts of acid and base have combined. To obtain this ideal result, selecting an appropriate indicator requires foresight. We will understand this better by studying how the pH of the solution being titrated changes with the addition of titrant.

When the pH of a solution at different stages of a titration is plotted against the volume of titrant added, we obtain a **titration curve**. The values of pH in these plots can be experimentally measured using a pH meter during the titration, or they can be calculated by the procedures we will describe below.

■ The *titrant* is the solution being slowly added from a buret to a solution in the receiving flask.

We will use the calculation method, and also demonstrate that all titration curves can be described by four calculations. Two calculations describe single points on the curve, the starting point and the equivalence point. The other two calculations are simple limiting reactant calculations for (a) mixtures between the start and the equivalence point and for (b) after the equivalence point.

TOOLS

Titration curves have four regions

Strong Acid–Strong Base Titrations

The titration of HCl(*aq*) with a standardized NaOH solution illustrates the titration of a strong acid by a strong base. The molecular and net ionic equations are

■ Not all acid–base reactions react the acid and base in a 1:1 ratio. We must always base our calculations on a balanced chemical equation.

$$HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O$$

$$H^+(aq) + OH^-(aq) \longrightarrow H_2O$$

Let’s consider what happens to the pH of a solution, initially 25.00 mL of 0.2000 *M* HCl, as small amounts of the titrant, 0.2000 *M* NaOH, are added. We will calculate the pH of the resulting solution at various stages of the titration, retaining only two decimal places, and plot the values against the volume of titrant.

An acid–base titration. Phenolphthalein is often used as an indicator to detect the end point. *(Peter Lerman)*

At the start, before any titrant has been added, the receiving flask contains only 0.2000 *M* HCl. Because this is a strong acid, we know that

$$[H^+] = [HCl] = 0.2000\ M$$

So the initial pH is

$$pH = -\log(0.2000) = 0.70$$

After the start but before the equivalence point we need to determine the concentration of the excess reactant in a simple limiting reactant problem. Let’s first calculate the amount of HCl initially present in 25.00 mL of 0.2000 *M* HCl.

$$25.00\ \cancel{\text{mL HCl soln}} \times \frac{0.2000\ \text{mol HCl}}{1000\ \cancel{\text{mL HCl soln}}} = 5.000 \times 10^{-3}\ \text{mol HCl}$$

Now suppose we add 10.00 mL of 0.2000 *M* NaOH from the buret. The amount of NaOH added is

$$10.00\ \cancel{\text{mL NaOH soln}} \times \frac{0.2000\ \text{mol NaOH}}{1000\ \cancel{\text{mL NaOH soln}}} = 2.000 \times 10^{-3}\ \text{mol NaOH}$$

■ Despite the high precision assumed for the molarity and the volume of the titrant, we will retain only two significant figures in the calculated pH. Precision higher than this is hard to obtain and seldom sought in actual lab work.

We can see that we have more moles of HCl than NaOH (and the mole ratio in the chemical equation is 1:1) so that the base neutralizes 2.000×10^{-3} mol of HCl, and the amount of HCl remaining is

$$(5.000 \times 10^{-3} - 2.000 \times 10^{-3})\ \text{mol HCl} = 3.000 \times 10^{-3}\ \text{mol HCl remaining}$$

To obtain the concentration we divide by the total volume of the solution that is now 25.00 mL + 10.00 mL = 35.00 mL = 0.03500 L. The $[H^+]$ is

■ $[H^+] = \dfrac{M_AV_A - M_BV_B}{V_A + V_B}$

$$[H^+] = \frac{3.000 \times 10^{-3}\ \text{mol}}{0.03500\ \text{L}} = 8.571 \times 10^{-2}\ M$$

The corresponding pH is 1.07.

We can repeat this calculation for as many different volumes as we care to choose as long as the volume of NaOH is less than the equivalence point volume. A spreadsheet will allow us to quickly calculate the pH of large numbers of data points, but only a few are needed to see the nature of the curve.

At the equivalence point we can calculate the volume of NaOH added as

$$\begin{aligned} M_{\text{HCl}} \times V_{\text{HCl}} &= M_{\text{NaOH}} \times V_{\text{NaOH}} \\ V_{\text{NaOH}}(\text{at eq pt}) &= \frac{(0.2000\ M_{\text{HCl}})(25.00\ \text{mL HCl})}{(0.2000\ M_{\text{NaOH}})} \\ &= 25.00\ \text{mL} \end{aligned}$$

■ The pH, at the equivalence point, of all strong acid–strong base titrations is 7.00.

■ $[OH^-] = \dfrac{M_BV_B - M_AV_A}{V_A + V_B}$

At this point we have exactly neutralized all of the acid with base and neither HCl nor NaOH are in excess. The solution contains only NaCl, and we have already observed that NaCl solutions are neutral with a pH = 7.00. The pH at the equivalence point of all strong acid–strong base titrations is 7.00.

After the equivalence point we will have an excess of base. As we did before, we calculate the moles of acid and the moles of base. Now the moles of base will be larger, and we subtract the moles of acid to find the excess moles of base. This is divided by the total volume to obtain the $[OH^-]$ from which the pH is calculated.

Table 17.5 shows the results of calculating the pH of the solution in the receiving flask after the addition of further small volumes of the titrant. Figure 17.7 shows a plot of the pH of the solution in the receiving flask versus the volume of the 0.2000 *M* NaOH solution added—the *titration curve* for the titration of a strong acid with a strong base. Notice how the pH of the solution increases slowly in a linear fashion until we are very close to the equivalence point, pH = 7.00. With the addition of a very small amount of base, the

Table 17.5 Titration of a Strong Acid with a Strong Base. The sample is 25.00 mL of 0.2000 *M* HCl and the titrant is 0.2000 *M* NaOH

Initial Volume of HCl (mL)	Initial Amount of HCl (mol)	Volume of NaOH Added (mL)	Amount of NaOH (mol)	Amount of Excess Reagent (mol)	Total Volume of Solution (mL)	Molarity of Ion in Excess (mol L^{-1})	pH
25.00	5.000×10^{-3}	0	0	5.000×10^{-3} (H^+)	25.00	0.2000 (H^+)	0.70
25.00	5.000×10^{-3}	10.00	2.000×10^{-3}	3.000×10^{-3} (H^+)	35.00	8.571×10^{-2} (H^+)	1.07
25.00	5.000×10^{-3}	20.00	4.000×10^{-3}	1.000×10^{-3} (H^+)	45.00	2.222×10^{-2} (H^+)	1.65
25.00	5.000×10^{-3}	24.00	4.800×10^{-3}	2.000×10^{-4} (H^+)	49.00	4.082×10^{-3} (H^+)	2.39
25.00	5.000×10^{-3}	24.90	4.980×10^{-3}	2.000×10^{-5} (H^+)	49.90	4.000×10^{-4} (H^+)	3.40
25.00	5.000×10^{-3}	24.99	4.998×10^{-3}	2.000×10^{-6} (H^+)	49.99	4.000×10^{-5} (H^+)	4.40
25.00	5.000×10^{-3}	25.00	5.000×10^{-3}	0	50.00	0	7.00
25.00	5.000×10^{-3}	25.01	5.002×10^{-3}	2.000×10^{-6} (OH^-)	50.01	3.999×10^{-5} (OH^-)	9.60
25.00	5.000×10^{-3}	25.10	5.020×10^{-3}	2.000×10^{-5} (OH^-)	50.10	3.992×10^{-4} (OH^-)	10.60
25.00	5.000×10^{-3}	26.00	5.200×10^{-3}	2.000×10^{-4} (OH^-)	51.00	3.922×10^{-3} (OH^-)	11.59
25.00	5.000×10^{-3}	50.00	1.000×10^{-2}	5.000×10^{-3} (OH^-)	75.00	6.667×10^{-2} (OH^-)	12.82

curve rises very sharply and then, almost as suddenly, bends to reflect just a gradual increase in pH.

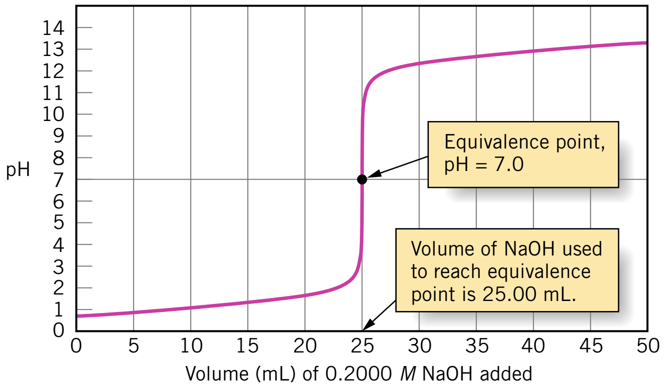
Weak Acid–Strong Base Titrations

The calculations for the titration of a weak acid by a strong base are a bit more complex than when both the acid and base are strong. This is because we have to consider the equilibria involving the weak acid and its conjugate base. As an example, let's do the calculations and draw a titration curve for the titration of 25.0 mL of 0.2000 *M* $HC_2H_3O_2$ with 0.2000 *M* NaOH. The same four points are calculated but they use different equations.

The molecular and net ionic equations we will use are

$$HC_2H_3O_2 + NaOH \longrightarrow NaC_2H_3O_2 + H_2O$$

$$HC_2H_3O_2 + OH^- \longrightarrow C_2H_3O_2^- + H_2O$$



Equivalence point, pH = 7.0

Volume of NaOH used to reach equivalence point is 25.00 mL.

Figure 17.7 | **Titration curve for titrating a strong acid with a strong base.** This graph shows how the pH changes during the titration of 0.2000 *M* HCl with 0.2000 *M* NaOH.

Because the concentrations of both solutions are the same, and because the acid and base react in a one-to-one mole ratio, we know that we will need exactly 25.0 mL of the base to reach the equivalence point. With this as background, let's look at what is involved in calculating the pH at various points along the titration curve.

■ The equivalence point in a titration can be found using a pH meter by plotting pH versus volume of base added and noting the sharp rise in pH. If a pH meter is used, we don't have to use an indicator.

At the start the solution is simply a solution of the weak acid, $HC_2H_3O_2$. We must use K_a to calculate the pH. We have seen that in many situations the assumptions hold and the calculations are summarized as

■ $[H^+] = \sqrt{K_a\ M_{HA}}$

$$K_a = \frac{[H^+][C_2H_3O_2^-]}{[HC_2H_3O_2]} = \frac{(x)(x)}{(0.200 - x)} \approx \frac{(x)(x)}{(0.200)} = 1.8 \times 10^{-5}$$

$$x^2 = 3.6 \times 10^{-6} \text{ (rounded)}$$

$$x = [H^+] = 1.9 \times 10^{-3}$$

This result gives us a pH of 2.72. This is the pH before any NaOH is added.

Between the start and the equivalence point. As we add NaOH to the $HC_2H_3O_2$, the chemical reaction produces $C_2H_3O_2^-$, so the solution contains both $HC_2H_3O_2$ and $C_2H_3O_2^-$ (it is a buffer solution). Our equilibrium law can be rearranged to read

$$[H^+] = \frac{K_a[HC_2H_3O_2]}{[C_2H_3O_2^-]} = \frac{K_a(\text{mol } HC_2H_3O_2)}{(\text{mol } C_2H_3O_2^-)}$$

Now all we need to do is solve a limiting reactant calculation to determine the moles of acetic acid, $HC_2H_3O_2$, left after each addition of NaOH and at the same time calculate the moles of acetate ion, $C_2H_3O_2^-$, formed.

Let's see what happens when we add 10.00 mL of NaOH solution. The initial moles of acetic acid are

■ Recall from Chapter 5 that molarity multiplied by volume (in liters) gives moles of solute.

$$0.2000\ M\ HC_2H_3O_2 \times 0.02500\ \text{L} = 5.000 \times 10^{-3} \text{ mol } HC_2H_3O_2$$

the moles of NaOH added are

$$0.20000\ M\ \text{NaOH} \times 0.01000\ \text{L} = 2.000 \times 10^{-3} \text{ mol NaOH}$$

The moles of acetic acid left are

$$5.000 \times 10^{-3} \text{ mol} - 2.000 \times 10^{-3} \text{ mol} = 3.000 \times 10^{-3} \text{ mol } HC_2H_3O_2$$

From the chemical equations above, the moles of NaOH added are stoichiometrically equal to the moles of acetate ion formed. We therefore have 2.000×10^{-3} mol $C_2H_3O_2^-$. Entering the values for the K_a and the moles of acetic acid and acetate ions we get

$$[\mathrm{H}^+] = \frac{(1.8 \times 10^{-5})(3.000 \times 10^{-3} \text{ mol } \mathrm{HC_2H_3O_2})}{(2.000 \times 10^{-3} \text{ mol } \mathrm{C_2H_3O_2^-})} = 2.7 \times 10^{-5}\ M$$

■ $[\mathrm{H}^+] = K_a \dfrac{M_A V_A - M_B V_B}{M_B V_B}$

and the pH is 4.57. We can obtain more data points by selecting volumes of added NaOH between zero and 25 mL and repeating the calculation methods we just used. To generate a very large number of data points, repetitive calculations can be performed using a spreadsheet and the equations used above.

At the equivalence point. Here all the $HC_2H_3O_2$ has reacted and the solution contains the salt $NaC_2H_3O_2$ (i.e., we have a mixture of the ions Na^+ and $C_2H_3O_2^-$).

We began with 5.00×10^{-3} mol of $HC_2H_3O_2$, so we now have 5.00×10^{-3} mol of $C_2H_3O_2^-$ (in 0.0500 L). The concentration of $C_2H_3O_2^-$ is

$$[\mathrm{C_2H_3O_2^-}] = \frac{5.00 \times 10^{-3} \text{ mol}}{0.0500 \text{ L}} = 0.100\ M$$

Because $C_2H_3O_2^-$ is a base, we have to use K_b and write the chemical equation for the reaction of a base with water.

$$\mathrm{C_2H_3O_2^-}(aq) + \mathrm{H_2O} \rightleftharpoons \mathrm{HC_2H_3O_2}(aq) + \mathrm{OH^-}(aq)$$

$$K_b = \frac{[\mathrm{OH^-}][\mathrm{HC_2H_3O_2}]}{[\mathrm{C_2H_3O_2^-}]} = \frac{K_w}{K_a} = 5.6 \times 10^{-10}$$

Substituting into the mass action expression gives

■ $[\mathrm{OH^-}] = \sqrt{K_b \dfrac{M_A V_A}{V_A + V_B}}$

$$\frac{[\mathrm{OH^-}][\mathrm{HC_2H_3O_2}]}{[\mathrm{C_2H_3O_2^-}]} = \frac{(x)(x)}{0.100 - x} \approx \frac{(x)(x)}{0.100} = 5.6 \times 10^{-10}$$

$$x^2 = 5.6 \times 10^{-11}$$

$$x = [\mathrm{OH^-}] = 7.5 \times 10^{-6}\ M$$

■ It is interesting that although we describe the overall reaction in the titration as *neutralization*, at the equivalence point the solution is slightly basic, not neutral.

The pOH calculates to be 5.12. Finally, the pH is (14.00 − 5.12) or 8.88. The pH at the equivalence point in this titration is 8.88, which is somewhat basic because the solution contains the Brønsted base, $C_2H_3O_2^-$. *In the titration of any weak acid with a strong base, the pH at the equivalence point will be greater than 7.*

After the equivalence point. Now the additional OH^- beyond the equivalence point shifts the following equilibrium to the left:

$$\mathrm{C_2H_3O_2^-}(aq) + \mathrm{H_2O} \rightleftharpoons \mathrm{HC_2H_3O_2}(aq) + \mathrm{OH^-}(aq)$$

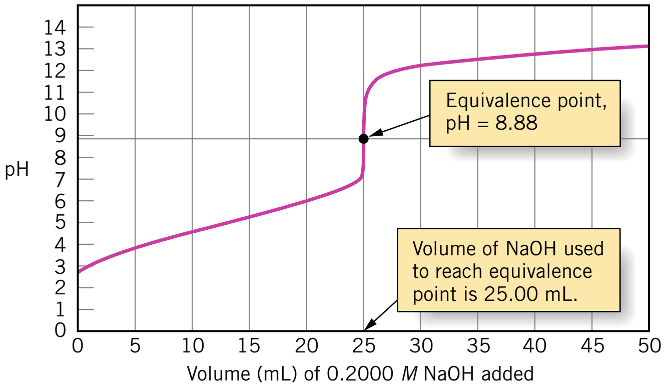
The production of OH^- *by this route* is thus suppressed as we add more and more NaOH solution. The only source of OH^- that affects the pH is from the base added after the equivalence point. From here on, therefore, the pH calculations become identical to those for the last half of the titration curve for HCl and NaOH shown above. Each point is just a matter of calculating the additional number of moles of NaOH, calculating the new final volume, taking their ratio (to obtain the molar concentration), and then calculating pOH and pH.

■ $[\mathrm{OH^-}] = \dfrac{M_B V_B - M_A V_A}{V_A + V_B}$

Table 17.6 summarizes the titration data, and the titration curve is given in Figure 17.8. Once again, notice how the change in pH occurs slowly at first, then shoots up through the equivalence point, and finally looks just like the last half of the curve in Figure 17.7.

Table 17.6 **Titration of a Weak Acid with a Strong Base. The sample is 25.00 mL of 0.2000 *M* $HC_2H_3O_2$ and the titrant is 0.2000 *M* NaOH.**

Volume of Base Added (mL)	Molar Concentration of Species in Parentheses	pH
None	1.9×10^{-3} (H^+)	2.72
10.00	2.7×10^{-5} (H^+)	4.57
24.90	7.2×10^{-8} (H^+)	7.14
24.99	7.1×10^{-9} (H^+)	8.14
25.00	7.5×10^{-6} (OH^-)	8.88
25.01	4.0×10^{-5} (OH^-)	9.60
25.10	4.0×10^{-4} (OH^-)	10.60
26.00	3.9×10^{-3} (OH^-)	11.59
35.00	3.3×10^{-2} (OH^-)	12.52



Equivalence point, pH = 8.88

Volume of NaOH used to reach equivalence point is 25.00 mL.

Figure 17.8 | **Titration curve for titrating a weak acid with a strong base.** In this titration, we follow the pH as 0.2000 *M* acetic acid is titrated with 0.2000 *M* NaOH.

Practice Exercises

17.45 | When a weak acid such as acetic acid, $HC_2H_3O_2$, is titrated with KOH what are ALL of the species in solution at (a) the equivalence point, (b) at the start of the titration, (c) after the equivalence point and (d) before the equivalence point. For each part list the species in order from highest concentration to lowest. (*Hint:* H_2O should be the first item in all your lists and either $[H^+]$ or $[OH^-]$ should be the lowest.)

17.46 | Suppose we titrate 20.0 mL of 0.100 *M* $HCHO_2$ with 0.100 *M* NaOH. Calculate the pH (a) before any base is added, (b) when half of the $HCHO_2$ has been neutralized, (c) after a total of 15.0 mL of base has been added, and (d) at the equivalence point.

17.47 | Suppose 30.0 mL of 0.15 *M* NaOH is added to 50.0 mL of 0.20 *M* $HCHO_2$. What will be the pH of the resulting solution?

Weak Base–Strong Acid Titrations

The calculations involved here are nearly identical to those of the weak acid–strong base titration. We will review what is required but will not actually perform the calculations.

If we titrate 25.00 mL of 0.2000 *M* NH_3 with 0.2000 *M* HCl, the molecular and net ionic equations are

$$NH_3(aq) + HCl(aq) \longrightarrow NH_4Cl(aq)$$
$$NH_3(aq) + H^+(aq) \longrightarrow NH_4^+(aq)$$

Before the titration begins. The solution at this point is simply a solution of the weak base, NH_3. Since the only solute is a base, we must use K_b to calculate the pH.

Between the start and the equivalence point. As we add HCl to the NH_3, the neutralization reaction produces NH_4^+, so the solution contains both NH_3 and NH_4^+ (it is a buffer solution). We do a limiting reactant calculation to determine the moles of ammonia left and the moles of ammonium ions produced by the addition of HCl. We use the equilibrium law to perform the calculation as we did with the weak acid.

At the equivalence point. Here all the NH_3 has reacted and the solution contains the salt NH_4Cl. We calculate the concentration of ammonium ions and then use the techniques we developed to determine the pH of the conjugate acid of a weak base.

After the equivalence point. The H^+ introduced by further addition of HCl has nothing with which to react, so it causes the solution to become more and more acidic. The concentration of H^+ calculated from the excess of HCl is used to calculate the pH.

Figure 17.9 illustrates the titration curve for this system.

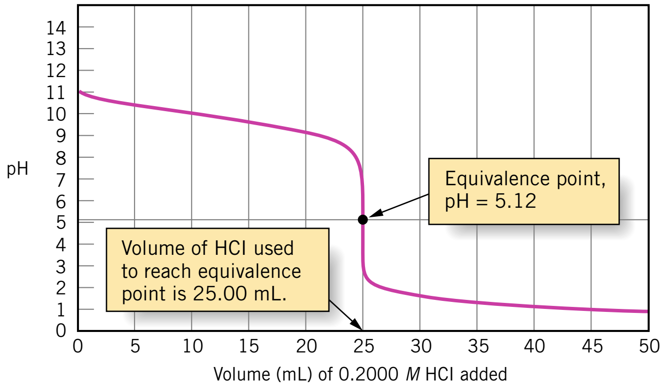


Figure 17.9 | **Titration curve for the titration of a weak base with a strong acid.** This graph shows how the pH changes as 0.2000 M NH_3 is titrated with 0.2000 M HCl.

Titration Curves for Diprotic Acids

When a weak diprotic acid such as ascorbic acid (vitamin C) is titrated with a strong base, there are two protons to be neutralized and there are two equivalence points. Provided that the values of K_{a_1} and K_{a_2} differ by at least four powers of 10, the neutralization takes place stepwise and the resulting titration curve shows two sharp increases in pH. We won't perform the calculations here because they're complex, but it is important to recognize the general shape of the titration curve, which is shown in Figure 17.10.

Acid–Base Indicators

■ Indicators and other molecules can absorb part of the visible spectrum of light. What is not absorbed is observed as the color. If a molecule absorbs the red and yellow wavelengths of light, it will look blue.

In Chapter 5 you learned that the end point of a titration could be detected when the color of the solution changed dramatically from one color to another. The substance that changed color was an acid–base indicator. Now we can understand how such indicators work.

Most dyes used as acid–base indicators are also weak acids. Therefore, let's represent an indicator molecule by the formula H*In*. In its un-ionized state, H*In* has one color. Its

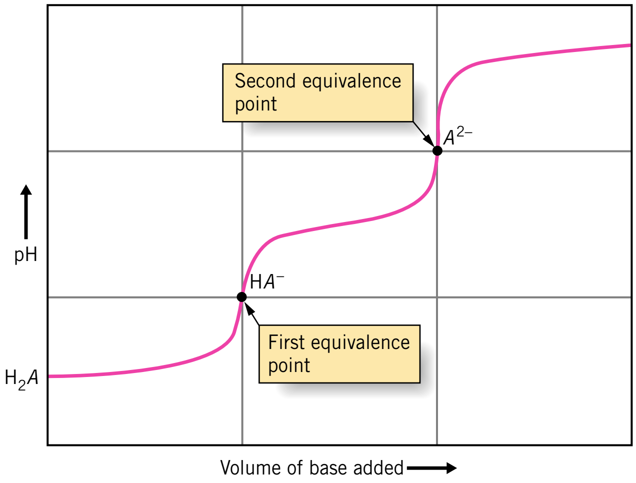

Figure 17.10 | **Titration of a diprotic acid, H_2A, by a strong base.** As each equivalence point is reached, there is a sharp rise in the pH.

Table 17.7 Common Acid—Base Indicators

Indicator	Approximate pH Range over which the Color Changes	Color Change (lower to higher pH)
Methyl green	0.2–1.8	Yellow to blue
Thymol blue	1.2–2.8	Yellow to blue
Methyl orange	3.2–4.4	Red to yellow
Ethyl red	4.0–5.8	Colorless to red
Methyl purple	4.8–5.4	Purple to green
Bromocresol purple	5.2–6.8	Yellow to purple
Bromothymol blue	6.0–7.6	Yellow to blue
Phenol red	6.4–8.2	Yellow to red/violet
Litmus	4.7–8.3	Red to blue
Cresol red	7.0–8.8	Yellow to red
Thymol blue	8.0–9.6	Yellow to blue
Phenolphthalein	8.2–10.0	Colorless to pink
Thymolphthalein	9.4–10.6	Colorless to blue
Alizarin yellow R	10.1–12.0	Yellow to red
Clayton yellow	12.2–13.2	Yellow to amber

conjugate base, In^-, has a different color, the more strikingly different the better. In solution, the indicator is involved in a typical acid–base equilibrium:

$$\underset{\substack{\text{Acid form}\\ \text{(one color)}}}{\mathrm{H}In(aq)} \rightleftharpoons \mathrm{H}^+(aq) + \underset{\substack{\text{base form}\\ \text{(another color)}}}{In^-(aq)}$$

TOOLS

How acid-base indicators work

The corresponding acid ionization constant, K_{In}, is given by

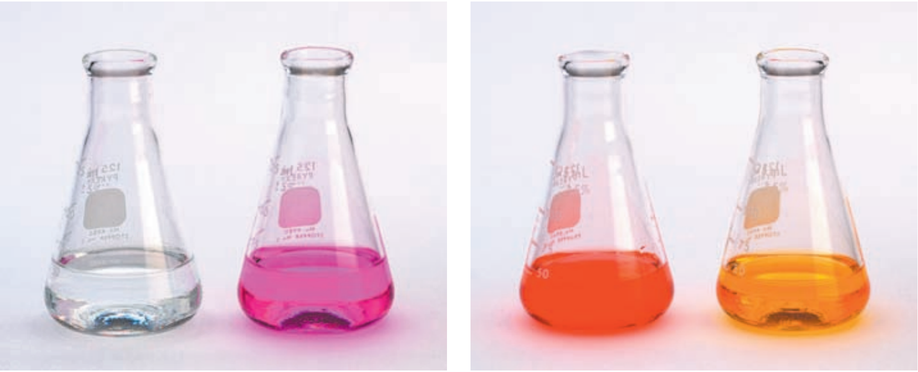
$$K_{\mathrm{In}} = \frac{[\mathrm{H}^+][In^-]}{[\mathrm{H}In]}$$

In a strongly acidic solution, when the H^+ concentration is high, the equilibrium is shifted to the left and most of the indicator molecules exist in its protonated or "acid form." Under these conditions, the color we observe is that of $\mathrm{H}In$. If the solution is made basic, the H^+ concentration decreases and the equilibrium shifts to the right, toward In^-, and the color we observe is that of the unprotonated "base form" of the indicator. Table 17.7 provides approximate pH ranges for the color changes of some common pH indicators.

It is generally agreed that if the ratio of $[\mathrm{HIn}]/[\mathrm{In}^-]$ is greater than 10 (i.e., the pH is 1 pH unit below the $\mathrm{p}K_{\mathrm{In}}$) the eye will see the color associated with the $\mathrm{H}In$ molecule. If the same ratio is less than 0.1 (i.e., the pH is 1 pH unit above the $\mathrm{p}K_{\mathrm{In}}$), the color seen is that of the anion In^-.

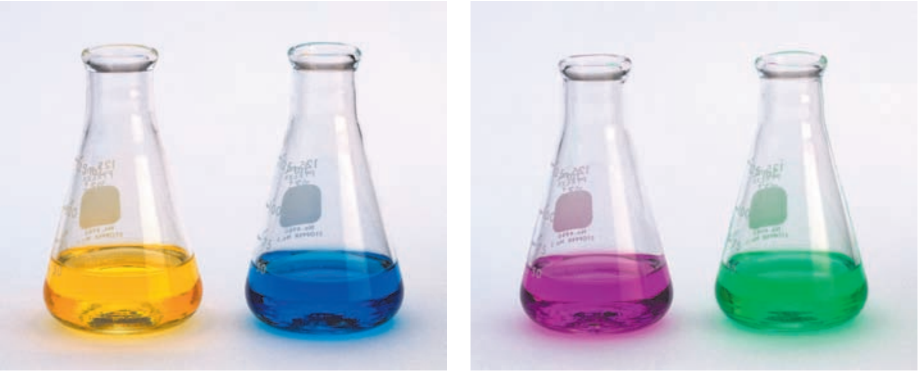
In typical acid–base titrations, we see that as we pass the equivalence point there is a sudden and large change in the pH, as shown in Figures 17.7–17.10. For example, in the titration of HCl with NaOH described earlier, the pH just one-half drop before the equivalence point (when 24.97 mL of the base has been added) is 3.92. Just one drop later (when 25.03 mL of base has been added) we have passed the equivalence point and the pH has risen to 10.08. This large swing in pH (from 3.92 to 10.08) causes a sudden shift in the position of equilibrium for the indicator, and we go from a condition where most

Figure 17.11 | **Colors of some common acid–base indicators.** *(Andy Washnik)*



pH 8.2 pH 10.0
Phenolphthalein
(*a*)

pH 3.2 pH 4.4
Methyl orange
(*b*)



pH 6.0 pH 7.6
Bromothymol blue
(*c*)

pH 4.8 pH 5.4
Methyl purple
(*d*)

of the indicator molecules are in the acid form to a condition in which most are in the base form. This is observed visually as a change in color from that of the acid form to that of the base form.

Measuring and Estimating pH

Earlier we saw that pH is usually measured with an instrument called a pH meter (Figure 17.2). We can now understand that a buffer solution is used to calibrate the pH meter because the pH of a buffer is reasonably stable. Typically, the accuracy of a pH meter is limited by the ±0.02 pH unit accuracy of the standardizing buffer. Modern pH meters can give much more precise readings if we are interested in changes in pH rather than the absolute pH value.

Another less precise method of obtaining the pH uses acid–base indicators. Table 17.7 gives several examples. Indicators change color over a narrow range of pH values, and Figure 17.11 shows the colors of some indicators at opposite ends of their color-change ranges. In addition, pH test papers are available that are impregnated with one or more indicator dyes. To obtain a rough idea of the pH, a drop of the solution to be tested is touched to a strip of the test paper and the resulting color is compared with a color code. Some commercial test papers (e.g., Hydrion) are impregnated with several dyes, with their containers carrying the color code (see Figure 17.12). Litmus paper was one of the first pH test papers ever made, and it is still commonly found in chemistry labs. It consists of porous paper impregnated with litmus dye, made either red or blue by exposure to acid or base and then dried.

Figure 17.12 | **Using a pH test paper.** The color of this Hydrion test strip changed to orange when a drop of the lemon juice solution in the beaker was placed on it. According to the color code, the pH of the solution is closer to 3 than to the color for pH 5. *(Andy Washnik)*

■ Litmus is extracted from a type of moss called lichens.

Below pH 4.7 litmus is red, and above pH 8.3 it is blue. The transition for the color change occurs over a pH range of 4.7 to 8.3 with the center of the change at about 6.5, very nearly a neutral pH. To test whether a solution is acidic, a drop of it is placed on blue litmus paper. If the dye turns pink, the solution is acidic. Similarly, to test if the solution is basic, a drop is touched to red litmus paper. If the dye turns blue, the solution is basic. If a solution is close to neutral, neither red nor blue litmus will change color.

Summary

The Autoionization of Water and the pH Concept. Water reacts with itself to produce small amounts of H_3O^+ (often abbreviated H^+) and OH^- ions. The concentrations of these ions, both in pure water and dilute aqueous solutions, are related by the expression

$$[H^+][OH^-] = K_w = 1.0 \times 10^{-14} \text{ (at 25 °C)}$$

$\boldsymbol{K_w}$ is the **ion product constant of water.** In pure water

$$[H^+] = [OH^-] = 1.0 \times 10^{-7}$$

The **pH** of a solution is defined by the equation, pH = − log [H^+]. Normally pH is measured with a pH meter and as the pH decreases, the acidity, or [H^+], increases. The comparable term, **pOH** (= −log [OH^-]), is used to describe a solution that is basic. As the hydroxide ion concentration decreases, the pOH increases. The pH and pOH are related by the expression

$$\text{pH} + \text{pOH} = 14.00$$

A solution is acidic if the hydrogen ion concentration exceeds 1.0×10^{-7} or the pH is less than 7.00. Similarly, a solution is basic if the hydroxide ion concentration exceeds 1.0×10^{-7} or if the pH is greater than 7.00.

Solutions of Strong Acids and Strong Bases. When calculating the pH of strong acids or strong bases, we assume that they are 100% ionized. The autoionization of water is suppressed in acid solutions and basic solutions. The result is that the hydrogen ion or hydroxide ion concentration from the autoionization of water is negligible.

Acid and Base Ionization Constants. A weak acid HA ionizes according to the general equation

$$HA + H_2O \rightleftharpoons H_3O^+ + A^-$$

or more simply,

$$HA \rightleftharpoons H^+ + A^-$$

The equilibrium constant is called the **acid ionization constant,** $\boldsymbol{K_a}$ (sometimes called an *acid dissociation constant*).

$$K_a = \frac{[H^+][A^-]}{[HA]}$$

A weak base B ionizes by the general equation

$$B + H_2O \rightleftharpoons BH^+ + OH^-$$

The equilibrium constant is called the **base ionization constant,** $\boldsymbol{K_b}$ (sometimes called a *base dissociation constant*).

$$K_b = \frac{[BH^+][OH^-]}{[B]}$$

The smaller the values of K_a (or K_b), the weaker are the substances as Brønsted acids (or bases).

Another way to compare the relative strengths of acids or bases is to use the negative logarithms of K_a and K_b, called **p$\boldsymbol{K_a}$** and **p$\boldsymbol{K_b}$**, respectively.

$$\text{p}K_a = -\log K_a \qquad \text{p}K_b = -\log K_b$$

Stronger acids or bases have *smaller* pK_a or pK_b values, respectively. For a conjugate acid–base pair,

$$K_a \times K_b = K_w$$

and

$$\text{p}K_a + \text{p}K_b = 14.00 \quad \text{(at 25 °C)}$$

Equilibrium Calculations—Determining K_a and K_b. The values of K_a and K_b can be obtained from initial concentrations of the acid or base and either the pH of the solution or the percentage ionization of the acid or base. The measured pH gives the equilibrium value for [H^+]. The **percentage ionization** is defined as

$$\text{percentage ionization} = \frac{\text{amount ionized}}{\text{amount available}} \times 100\%$$

Equilibrium Calculations—Determining Equilibrium Concentrations When K_a or K_b Is Known. Problems fall into one of three categories: (1) the only solute is a weak acid (we must use the K_a expression), (2) the only solute is a weak base (we must use the K_b expression), and (3) the solution contains both a weak acid and its conjugate base (we can use either K_a or K_b).

When the initial concentration of the acid (or base) is larger than 100 times the value of K_a (or K_b), it is safe to use initial concentrations of acid or base as though they were equilibrium values in the mass action expression. When this approximation cannot be used, we can use the quadratic formula.

Ions as Acids or Bases. A solution of a salt is acidic if the cation is acidic but the anion is neutral. Metal ions with high charge densities generally are acidic, but those of Groups 1A and 2A (except Be^{2+}) are not. Cations such as NH_4^+, which are the conjugate acids of weak *molecular* bases, are themselves proton donors and are acidic.

When the anion of a salt is the conjugate base of a *weak* acid, the anion is a weak base. Anions of strong acids, such as Cl^- and NO_3^-, are such weak Brønsted bases that they cannot affect the pH of a solution.

If the salt is derived from a weak acid *and* a weak base, its net effect on pH has to be determined on a case-by-case basis by determining which of the two ions is the stronger.

Buffers. A solution that contains both a weak acid and a weak base (usually an acid–base conjugate pair) is called a **buffer,** because it is able to absorb $[H^+]$ from a strong acid or $[OH^-]$ from a strong base without large changes in pH. For the general acid–base pair, HA and A^-, the following reactions neutralize H^+ and OH^-. When H^+ is added to the buffer:

$$A^- + H^+ \longrightarrow HA$$

When OH^- is added to the buffer:

$$HA + OH^- \longrightarrow A^- + H_2O$$

The pH of a buffer is controlled by the ratio of weak acid to weak base, expressed either in terms of molarities or moles.

$$[H^+] = K_a \times \frac{[HA]}{[A^-]} = K_a \times \frac{\text{moles } HA}{\text{moles } A^-}$$

Because the $[H^+]$ is determined by the mole ratio of HA to A^-, dilution does not change the pH of a buffer. The **Henderson–Hasselbalch equation,**

$$\text{pH} = \text{p}K_a + \log\frac{[A^-]}{[HA]}$$

can be used to calculate the pH directly from the $\text{p}K_a$ of the acid and the concentrations of the conjugate acid, HA, and base, A^-.

In performing buffer calculations, the usually valid simplifications are

$$[HA]_{\text{equilibrium}} \approx [HA]_{\text{initial}}$$
$$[A^-]_{\text{equilibrium}} \approx [A^-]_{\text{initial}}$$

The value of $[A^-]_{\text{initial}}$ is found from the molarity of the *salt* of the weak acid in the buffer. Once $[H^+]$ is found by this calculation, the pH is calculated.

Buffer calculations can also be performed using K_b for the weak base component. Similar equations apply, the principal difference being that it is the OH^- concentration that is calculated. Thus, using K_b we have

$$[OH^-] = K_b \times \frac{[\text{conjugate base}]}{[\text{conjugate acid}]}$$
$$= K_b \times \frac{(\text{moles conjugate base})}{(\text{moles conjugate acid})}$$

Buffers are most effective when the $\text{p}K_a$ of the acid member of the buffer pair lies within ± 1 unit of the desired pH.

Equilibria in Solutions of Polyprotic Acids. A polyprotic acid has a K_a value for the ionization of each of its hydrogen ions. Successive values of K_a often differ by a factor of 10^4 to 10^5. This allows us to calculate the pH of a solution of a polyprotic acid by using just the value of K_{a_1}. If the polyprotic acid is the only solute, the anion formed in the second step of the ionization, A^{2-}, has a concentration equal to K_{a_2}.

The anions of weak polyprotic acids are bases that react with water in successive steps, the last of which has the molecular polyprotic acid as a product. For a diprotic acid, $K_{b_1} = K_w/K_{a_2}$ and $K_{b_2} = K_w/K_{a_1}$. Usually, $K_{b_1} \gg K_{b_2}$, so virtually all the OH^- produced in the solution comes from the first step. The pH of the solution can be calculated using just K_{b_1} and the reaction

$$A^{2-} + H_2O \rightleftharpoons HA^- + OH^-.$$

Acid–Base Titrations and Indicators. Neutralization titrations can be experimentally measured using a pH meter or they can be calculated using the principles developed in this chapter. Both methods yield the same result, a titration curve. The titration curve contains important information about the chemical system including the equivalence point and equilibrium constant data.

Each calculated titration curve has four distinct calculations:

(a) The starting pH of a solution that contains only an acid or base
(b) The pH values for titrant volumes between the start and the equivalence points
(c) The pH at the equivalence point
(d) The pH values for titrant volumes past the equivalence point

A graph of the pH values versus the volume of titrant gives us a titration curve. Titration curves show a sharp change in pH at the equivalence point. **Titration curves** also have distinct differences in shape when strong acid–strong base titrations are compared to weak acid–weak base titrations.

Acid–base indicators are weak acids in which the conjugate acid and base have different colors. The sudden change in pH at the equivalence point causes a rapid shift from one color of the indicator to the other. If matched to the equivalence point, a pH indicator will change color abruptly when a titration reaches the equivalence point.

Tools for Problem Solving

The concepts that you've learned in this chapter can be applied as tools in solving problems. If necessary, refer to this table when working on the review exercises and problems that follow.

Ion product constant of water, K_w (page 774)

$$K_w = [H^+][OH^-] \qquad \text{or} \qquad K_w = [H_3O^+][OH^-]$$

At 25 °C the value of K_w is 1.0×10^{-14}. This equation allows us to convert between hydrogen (hydronium) ion concentrations and hydroxide ion concentrations. It also demonstrates that the hydrogen ion concentration is inversely proportional to the hydroxide concentration.

Definition of pH (page 776)

$$\text{pH} = -\log [H^+]$$

The pH scale was developed to conveniently represent the very small numbers usually encountered when working with acid–base equilibria. As the hydrogen ion concentration increases, the pH decreases.

Defining the p-function, pX (page 777)

$$\text{p}X = -\log X$$

A p-function is formulated as the logarithm of a value with the sign changed. As with pH, it is a convenient way to represent very small numbers.

Relating pH and pOH to pK_w (page 777)

$$\text{pH} + \text{pOH} = \text{p}K_w$$

Adding the pH and pOH always gives us 14.00 at 25 °C. This is an easy way to convert between pH and pOH.

General equation for the ionization of a weak acid (page 780)

$$HA + H_2O \rightleftharpoons H_3O^+ + A^- \qquad \text{or} \qquad HA \rightleftharpoons H^+ + A^-$$

You follow the form of the general equation to write the correct chemical equilibrium for a given weak acid, from which you construct the correct K_a expression.

General equation for the ionization of a weak base (page 782)

$$B + H_2O \rightleftharpoons BH^+ + OH^-$$

You follow the form of the general equation to write the correct chemical equilibrium for a given weak base, from which you construct the correct K_b expression.

Inverse relationship between K_a and K_b (page 783)

$$K_a \times K_b = K_w$$

Use this equation to calculate K_a, given K_b, or vice versa.

Relationship between pK_a and pK_b (page 783)

$$\text{p}K_a + \text{p}K_b = \text{p}K_w$$

This equation allows us to determine the equilibrium constant of a conjugate base if we know the equilibrium constant of the conjugate acid and vice versa.

Percentage ionization (page 784)

$$\text{percentage ionization} = \frac{\text{moles per liter ionized}}{\text{moles per liter available}} \times 100\%$$

Use this equation to calculate the percentage ionization from the initial concentration of acid (or base) and the change in the concentrations of the ions. If the percentage ionization is known, you can calculate the change in the concentration of the acid or base and then use that information to calculate the K_a (or K_b).

Criterion for predicting if simplifying assumptions will work (page 793)

$$C_{HA} > 100 \times K_a \qquad \text{or} \qquad C_B > 100 \times K_b$$

If this relationship is true, initial concentrations can be used as though they are equilibrium values in the mass action expression when working acid–base equilibrium problems. The error from this assumption is a maximum of 5% in $[H^+]$ or $[OH^-]$. If the condition fails, then we have to use the quadratic equation or the method of successive approximations.

Identification of acidic cations and basic anions (pages 794 and 795)

We use the concepts developed here to determine whether a salt solution is acidic, basic, or neutral. This is also the first step in calculating the pH of a salt solution.

How buffers work (page 798)

These reactions illustrate how the concentrations of conjugate acid and base change when a strong acid or strong base is added to a buffer. Adding H^+ decreases $[A^-]$ and increases $[HA]$; adding OH^- decreases $[HA]$ and increases $[A^-]$. These reactions keep the pH of the solution from changing drastically.

Polyprotic acids ionize stepwise (page 805)

Polyprotic acids have more than one ionizable proton in their formulas. Each proton will ionize sequentially and the chemical equation will have a form similar to the general equation for the ionization of a weak acid tool above.

Titration curves have four regions (pages 811 to 815)

A titration curve is a graph of the pH as a function of the volume of titrant added to a sample. To plot such a curve, there are four different stages of calculation. They are (a) the starting point, (b) the stage from the start to the equivalence point, (c) the equivalence point, and (d) the stage after the equivalence point.

How acid-base indicators work (page 817)

Titration indicators are weak acids that have one color for the conjugate acid and a different color for the conjugate base. Whether the indicator is in the conjugate acid or conjugate base form depends on the pH. The rapid, large change in pH at a titration end point results in a distinct color change that signals a titration end point.

Review Questions

Ionization of Water and the pH Concept

17.1 Write the chemical equation for **(a)** the autoionization of water and **(b)** the equilibrium law for K_w.

17.2 How are acidic, basic, and neutral solutions in water defined **(a)** in terms of $[H^+]$ and $[OH^-]$ and **(b)** in terms of pH and pOH?

17.3 At 25 °C, how are the pH and pOH of a solution related to each other?

17.4 Explain how acids and bases suppress the ionization of water, often called the common ion effect.

17.5 Explain the leveling effect of water.

Strong Acids and Strong Bases

17.6 List the strong acids.

17.7 What chemical property is central to our classifying an acid as a strong acid?

17.8 How are strong bases identified?

17.9 Some strong bases can be used to safely reduce stomach acidity (heartburn). What differentiates strong bases that are safe medicines from those that could cause irreparable harm?

Acid and Base Ionization Constants: K_a, K_b, pK_a, and pK_b

17.10 Write the general equation for the ionization of a weak acid, H*A*, in water. Give the equilibrium law corresponding to K_a.

17.11 Write the chemical equation for the ionization of each of the following weak acids in water. (For polyprotic acids, write only the equation for the first step in the ionization.)

(a) HNO_2
(b) H_3PO_4
(c) $HAsO_4^{2-}$
(d) $(CH_3)_3NH^+$

17.12 For each of the acids in Review Question 17.11 write the appropriate K_a expression.

17.13 Write the general equation for the ionization of a weak base, *B*, in water. Give the equilibrium law corresponding to K_b.

17.14 Write the chemical equation for the ionization of each of the following weak bases in water.

(a) $(CH_3)_3N$
(b) AsO_4^{3-}
(c) NO_2^-
(d) $(CH_3)_2N_2H_2$

17.15 For each of the bases in Review Question 17.14, write the appropriate K_b expression.

17.16 The pK_a of HCN is 9.31 and that of HF is 3.46. Which is the stronger Brønsted base, CN^- or F^-?

17.17 Write the structural formulas for the conjugate acids of the following:

(a) 
$$CH_3{-}CH_2{-}\underset{..}{\overset{\overset{\displaystyle CH_3}{|}}{N}}{-}H$$

(b) 
(c) 
$$H{-}\underset{..}{\ddot{O}}{-}\underset{..}{\overset{\overset{\displaystyle H}{|}}{N}}{-}H$$

17.18 Write the structural formulas for the conjugate bases of the following:

(a) 
(b) 
$$\left[CH_3{-}\underset{\underset{\displaystyle CH_3}{|}}{\overset{\overset{\displaystyle CH_3}{|}}{N}}{-}H\right]^+$$

(c) 
$$\left[H{-}\underset{..}{\overset{\overset{\displaystyle H}{|}}{N}}{-}\underset{\underset{\displaystyle H}{|}}{\overset{\overset{\displaystyle H}{|}}{N}}{-}H\right]^+$$

17.19 How is percentage ionization defined? Write the equation.

17.20 What criterion do we use to determine whether or not the equilibrium concentration of an acid or base will be effectively the same as its initial concentration when we calculate the pH of the solution?

17.21 For which of the following are we permitted to make the assumption that the equilibrium concentration of the acid or base is the same as the initial concentration when we calculate the pH of the solution specified?

(a) 0.020 *M* $HC_2H_3O_2$
(b) 0.10 *M* CH_3NH_2
(c) 0.002 *M* N_2H_4
(d) 0.050 *M* $HCHO_2$

Acid–Base Properties of Salt Solutions

17.22 Aspirin is acetylsalicylic acid, a monoprotic acid whose K_a value is 3.3×10^{-4}. Does a solution of the sodium salt of aspirin in water test acidic, basic, or neutral? Explain.

17.23 The K_b value of the oxalate ion, $C_2O_4^{2-}$, is 1.6×10^{-10}. Is a solution of $K_2C_2O_4$ acidic, basic, or neutral? Explain.

17.24 Consider the following compounds and suppose that 0.5 *M* solutions are prepared of each: NaI, NH_4Br, KF, KCN, $KC_2H_3O_2$, $CsNO_3$, and Kbr. Write the *formulas* of those that have solutions that are **(a)** acidic, **(b)** basic, and **(c)** neutral.

17.25 Will an aqueous solution of $AlCl_3$ turn litmus red or blue? Explain.

17.26 A solution of hydrazinium acetate is slightly acidic. Without looking at the tables of equilibrium constants, is K_a for acetic acid larger or smaller than K_b for hydrazine? Justify your answer.

***17.27** When ammonium nitrate is added to a suspension of magnesium hydroxide in water, the $Mg(OH)_2$ dissolves. Write a net ionic equation to show how this occurs.

Buffers

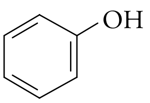
17.28 Write ionic equations that illustrate how each pair of compounds can serve as a buffer pair.

(a) H_2CO_3 and $NaHCO_3$ (the "carbonate" buffer in blood)

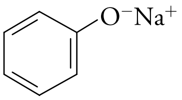
(b) NaH_2PO_4 and Na_2HPO_4 (the "phosphate" buffer inside body cells)

(c) NH_4Cl and NH_3

(d) Phenol and sodium phenolate



and



17.29 The hydrogen phosphate ion is able to act as a buffer all by itself. Write chemical equations that show how this ion reacts with **(a)** H^+ and **(b)** OH^-.

Ionization of Polyprotic Acids

17.30 When sulfur dioxide, an air pollutant from the burning of sulfur-containing coal or oil, dissolves in water, an acidic solution is formed that can be viewed as containing sulfurous acid, H_2SO_3.

$$H_2O + SO_2(g) \rightleftharpoons H_2SO_3(aq)$$

Write the expression for K_{a_1} and K_{a_2} for sulfurous acid.

17.31 Citric acid, found in citrus fruits, is a triprotic acid, $H_3C_6H_5O_7$. Write chemical equations for the three-step ionization of this acid in water and write the three K_a expressions (equilibrium laws).

17.32 What simplifying assumptions do we usually make in working problems involving the ionization of polyprotic acids? Why are they usually valid? Under what conditions do they fail?

Salts of Polyprotic Acids

17.33 Write the equations for the chemical equilibria that exist in solutions of **(a)** Na_2SO_3, **(b)** Na_3PO_4, and **(c)** $K_2C_4H_4O_6$.

17.34 What simplifying assumptions do we usually make in working problems involving equilibria of salts of polyprotic acids? Why are they usually valid? Under what conditions do they fail?

Titrations and Acid–Base Indicators

17.35 Define the terms equivalence point and end point as they apply to an acid–base titration.

17.36 When a formic acid solution is titrated with sodium hydroxide, will the solution be acidic, neutral, or basic at the equivalence point?

17.37 When a solution of hydrazine is titrated with hydrochloric acid, will the solution be acidic, neutral, or basic at the equivalence point?

17.38 Qualitatively, describe how an acid–base indicator works. Why do we want to use a minimum amount of indicator in a titration?

17.39 If you use methyl orange in the titration of $HC_2H_3O_2$ with NaOH, will the end point of the titration correspond to the equivalence point? If not, suggest a better indicator for this titration. Justify your answer.

Review Problems

Autoionization of Water and pH

17.40 Deuterium oxide, D_2O, ionizes like water. At 20 °C its K_w or ion product constant, analogous to that of water, is 8.9×10^{-16}. Calculate $[D^+]$ and $[OD^-]$ in deuterium oxide at 20 °C. Calculate also the pD and the pOD.

17.41 At the temperature of the human body, 37 °C, the value of K_w is 2.5×10^{-14}. Calculate $[H^+]$, $[OH^-]$, pH, and pOH of pure water at this temperature. What is the relationship between pH, pOH, and pK_w at this temperature? Is water neutral at this temperature?

17.42 Calculate the $[H^+]$, pH, and pOH in each of the following solutions in which the hydroxide ion concentrations are

(a) 0.0068 *M*

(b) 6.4×10^{-5} *M*

(c) 1.6×10^{-8} *M*

(d) 8.2×10^{-12} *M*

17.43 Calculate the $[OH^-]$, pH, and pOH for each of the following solutions in which the H^+ concentrations are

(a) 3.5×10^{-7} *M*

(b) 0.0017 *M*

(c) 2.5×10^{-11} *M*

(d) 7.9×10^{-2} *M*

17.44 A certain brand of beer had a H^+ concentration equal to 1.9×10^{-5} mol L^{-1}. What is the pH of the beer?

17.45 A soft drink was put on the market with $[H^+] = 1.4 \times 10^{-5}$ mol L^{-1}. What is its pH?

17.46 Calculate the molar concentrations of H^+ and OH^- in solutions that have the following pH values.

(a) 8.14 **(b)** 2.56 **(c)** 11.25 **(d)** 13.28 **(e)** 6.70

17.47 Calculate the molar concentrations of H^+ and OH^- in solutions that have the following pOH values.

(a) 12.27 **(b)** 6.14 **(c)** 10.65 **(d)** 4.28 **(e)** 3.76

17.48 The interaction of water droplets in rain with carbon dioxide that is naturally present in the atmosphere causes rain water to be slightly acidic because CO_2 is an acidic anhydride. As a result, pure clean rain has a pH of about 5.7. What are the hydrogen ion and hydroxide ion concentrations in this rain water?

17.49 "Acid rain" forms when rain falls through air polluted by oxides of sulfur and nitrogen, which dissolve to form acids such as H_2SO_3, H_2SO_4, and HNO_3. Trees and plants are affected if the acid rain has a pH of 3.5 or lower. What is the hydrogen ion concentration in acid rain that has a pH of 3.16? What is the pH of a solution having twice your calculated hydrogen ion concentration?

Solutions of Strong Acids and Bases

17.50 What is the concentration of H^+ in 0.00065 *M* HNO_3? What is the pH of this solution? What is the OH^- concentration in this solution?

17.51 What is the concentration of H^+ in 0.031 *M* $HClO_4$? What is the pH of the solution? What is the OH^- concentration in the solution? By how much does the pH change if the concentration of H^+ is doubled?

17.52 A sodium hydroxide solution is prepared by dissolving 6.0 g NaOH in 1.00 L of solution. What is the molar concentration of OH^- in the solution? What are the pOH and the pH of the solution? What is the hydrogen ion concentration in the solution?

17.53 A solution was made by dissolving 0.837 g $Ba(OH)_2$ in 100 mL final volume. What is the molar concentration of OH^- in the solution? What are the pOH and the pH? What is the hydrogen ion concentration in the solution?

17.54 A solution of $Ca(OH)_2$ has a measured pH of 11.60. What is the molar concentration of the $Ca(OH)_2$ in the solution? What is the molar concentration of $Ca(OH)_2$ if the solution is diluted so that the pH is 10.60?

17.55 A solution of HCl has a pH of 2.50. How many grams of HCl are there in 0.250 L of this solution? How many grams of HCl are in 250 mL of an HCl solution that has twice this pH?

17.56 In a 0.0020 *M* solution of NaOH, how many moles per liter of OH^- come from the ionization of water?

17.57 In a certain solution of HCl, the ionization of water contributes 3.4×10^{-11} moles per liter to the H^+ concentration. What is the total H^+ concentration in the solution?

***17.58** A solution was prepared with 2.64 micrograms of $Ba(OH)_2$ in 1.00 liter of water. What is the pH of the solution, and what concentration of hydrogen ions is provided by the ionization of water?

***17.59** What is the pH of a 3.0×10^{-7} *M* solution of HCl? What concentration of hydrogen ions is provided by the ionization of water?

***17.60** A 1.0 *M* solution of acetic acid has a pH of 2.37. What percentage of the acetic acid is ionized in the solution?

***17.61** A 0.250 *M* solution of NH_3 has a pH of 11.32. What percentage of the ammonia is ionized in this solution?

Acid and Base Ionization Constants: K_a, K_b, pK_a, and pK_b

17.62 The K_a for HF is 6.8×10^{-4}. What is the K_b for F^-?

17.63 The barbiturate ion, $C_4H_3N_2O_3{}^-$, has $K_b = 1.0 \times 10^{-10}$. What is the K_a for barbituric acid?

17.64 Lactic acid, $HC_3H_5O_3$, is responsible for the sour taste of old milk. At 25 °C, its $K_a = 1.4 \times 10^{-4}$. **(a)** What is the K_b of its conjugate base, the lactate ion, $C_3H_5O_3{}^-$? **(b)** Is its conjugate base a stronger or a weaker base than the acetate ion?

OH **17.65** Iodic acid, HIO_3, has a pK_a of 0.77. **(a)** What are the formula and the K_b of its conjugate base? **(b)** Is its conjugate base a stronger or a weaker base than the acetate ion?

Equilibrium Calculations

17.66 A 0.20 *M* solution of a weak acid, H*A*, has a pH of 3.22. What is the percentage ionization of the acid? What is the value of K_a for the acid?

17.67 If a weak base is 0.030% ionized in 0.030 *M* solution, what is the pH of the solution? What is the value of K_b for the base?

OH **17.68** Periodic acid, HIO_4, is an important oxidizing agent and a moderately strong acid. In a 0.10 *M* solution, $[H^+] = 3.8 \times 10^{-2}$ mol L^{-1}. Calculate the K_a and pK_a for periodic acid.

17.69 Chloroacetic acid, $HC_2H_2O_2Cl$, is a stronger monoprotic acid than acetic acid. In a 0.10 *M* solution, the pH is 1.96. Calculate the K_a and pK_a for chloroacetic acid.

ILW **17.70** Ethylamine, $CH_3CH_2NH_2$, has a strong, pungent odor similar to that of ammonia. Like ammonia, it is a Brønsted base. A 0.10 *M* solution has a pH of 11.87. Calculate the K_b and pK_b for ethylamine. What is the percentage ionization of ethylamine in this solution?

17.71 Hydroxylamine, $HONH_2$, like ammonia, is a Brønsted base. A 0.15 *M* solution has a pH of 10.11. What are the K_b and pK_b values for hydroxylamine? What is the percentage ionization of the $HONH_2$?

ILW ***17.72** What are the concentrations of all the solute species in 0.150 *M* lactic acid, $HC_3H_5O_2$? What is the pH of the solution? This acid has a $K_a = 1.4 \times 10^{-4}$.

***17.73** What are the concentrations of all the solute species in a 1.0 *M* solution of hydrogen peroxide, H_2O_2? What is the pH of the solution? For H_2O_2, $K_a = 2.4 \times 10^{-12}$.

17.74 Codeine, a cough suppressant extracted from crude opium, is a weak base with a pK_b of 5.80. What will be the pH of a 0.020 *M* solution of codeine? (Use *Cod* as a symbol for codeine.)

17.75 Pyridine, C_5H_5N, is a bad-smelling liquid that is a weak base in water. Its pK_b is 8.77. What is the pH of a 0.20 *M* aqueous solution of this compound?

17.76 A solution of acetic acid has a pH of 2.54. What is the concentration of acetic acid in this solution?

17.77 How many moles of NH_3 must be dissolved in water to give 500. 0 mL of solution with a pH of 11.22?

Equilibrium Calculations when Simplifications Fail

***17.78** What is the pH of a 0.0050 *M* solution of sodium cyanide?

***17.79** What is the pH of a 0.020 *M* solution of chloroacetic acid, for which $K_a = 1.4 \times 10^{-3}$?

17.80 The compound *para*-aminobenzoic acid (PABA) is a powerful sun-screening agent whose salts were once used widely in sun tanning and screening lotions. The parent acid, which we may symbolize as H-*Paba*, is a weak acid with a pK_a of 4.92 (at 25 °C). What are the $[H^+]$ and pH of a 0.030 *M* solution of this acid?

17.81 Barbituric acid, $HC_4H_3N_2O_3$ (which we will abbreviate H-*Bar*), was discovered by the Nobel Prize–winning organic chemist Adolph von Bayer and named after his friend, Barbara. It is the parent compound of widely used sleeping drugs, the barbiturates. Its pK_a is 4.01. What are the $[H^+]$ and pH of a 0.020 *M* solution of H-*Bar*?

Acid–Base Properties of Salt Solutions

17.82 Calculate the pH of 0.20 *M* NaCN. What is the concentration of HCN in the solution?

17.83 Calculate the pH of 0.40 *M* KNO_2. What is the concentration of HNO_2 in the solution?

ILW **17.84** Calculate the pH of 0.15 *M* CH_3NH_3Cl. For methylamine, CH_3NH_2, $K_b = 4.4 \times 10^{-4}$.

17.85 Calculate the pH of 0.10 *M* hydrazinium chloride, N_2H_5Cl.

17.86 A 0.18 *M* solution of the sodium salt of nicotinic acid (also known pharmaceutically as niacin) has a pH of 9.05. What is the value of K_a for nicotinic acid?

17.87 A weak base *B* forms the salt *B*HCl, composed of the ions BH^+ and Cl^-. A 0.15 *M* solution of the salt has a pH of 4.28. What is the value of K_b for the base *B*?

OH ***17.88** Liquid chlorine bleach is really nothing more than a solution of sodium hypochlorite, NaOCl, in water. Usually, the concentration is approximately 5.1% NaOCl by weight. Use this information to calculate the approximate pH of a bleach solution, assuming no other solutes are in the solution except NaOCl. (Assume the bleach has a density of 1.0 g/mL.)

***17.89** The conjugate acid of a molecular base has the general formula, BH^+ and a pK_a of 5.00. A solution of a salt of this cation, *BHY*, tests slightly basic. Will the conjugate acid of Y^-, H*Y*, have a pK_a greater than 5.00 or less than 5.00? Explain.

Buffers

17.90 What is the pH of a solution that contains 0.15 *M* $HC_2H_3O_2$ and 0.25 *M* $C_2H_3O_2^-$? Use $K_a = 1.8 \times 10^{-5}$ for $HC_2H_3O_2$.

17.91 Rework the preceding problem using the K_b for the acetate ion. (Be sure to write the proper chemical equation and equilibrium law.)

OH **17.92** A buffer is prepared containing 0.25 *M* NH_3 and 0.45 *M* NH_4^+. Calculate the pH of the buffer using the K_b for NH_3.

17.93 Calculate the pH of the buffer in the preceding problem using the K_a for NH_4^+.

***17.94** Certain proteolytic enzymes react in alkaline solutions. One of these enzymes produces 1.8 micromoles of hydrogen ions per second in a 2.50 mL portion of a buffer composed of 0.25 *M* NH_3 and 0.20 *M* NH_4Cl. By how much will the concentrations of the NH_3 and NH_4^+ ions change after the reaction has run for 35 seconds?

***17.95** A hydrolytic enzyme consumes 1.8×10^{-7} moles of hydrogen ions per minute in 2.50 mL of a buffer that contained 0.15 *M* $HC_2H_3O_2$ and 0.25 *M* $C_2H_3O_2^-$. By how much did the concentrations of $HC_2H_3O_2$ and $C_2H_3O_2^-$ change after the enzyme reacted for 3.45 minutes?

***17.96** By how much will the pH change if 0.025 mol of HCl is added to 1.00 L of the buffer in Review Problem 17.90?

***17.97** By how much will the pH change if 25.0 mL of 0.20 *M* NaOH is added to 0.500 L of the buffer in Review Problem 17.92?

***17.98** What are the initial and final pH values for the buffer in Review Problem 17.94? What is the change in pH?

***17.99** What are the initial and final pH values for the buffer in Review Problem 17.95? What is the change in pH?

17.100 How many grams of sodium acetate, $NaC_2H_3O_2$, would have to be added to 1.0 L of 0.15 *M* acetic acid (pK_a 4.74) to make the solution a buffer for pH 4.00?

17.101 How many grams of sodium formate, $NaCHO_2$, would have to be dissolved in 1.0 L of 0.12 *M* formic acid (pK_a 3.74) to make the solution a buffer for pH 3.50?

***17.102** Suppose 30.00 mL of 0.100 *M* HCl is added to an acetate buffer prepared by dissolving 0.100 mol of acetic acid and 0.110 mol of sodium acetate in 0.100 L of solution. What are the initial and final pH values? What would be the pH if the same amount of HCl solution were added to 125 mL of pure water?

***17.103** How many milliliters of 0.15 *M* HCl would have to be added to the original 0.100 L of the buffer described in Review Problem 17.92 to make the pH decrease by 0.05 pH unit? How many milliliters of the same HCl solution would, if added to 0.100 L of pure water, make the pH decrease by 0.05 pH unit?

Solutions of Polyprotic Acids

ILW ***17.104** Calculate the concentrations of all the solute species in a 0.15 *M* solution of ascorbic acid (vitamin C). What is the pH of the solution?

***17.105** Tellurium, in the same family as sulfur, forms an acid analogous to sulfuric acid and called telluric acid. It exists, however, as H_6TeO_6 (which can be understood as the formula $H_2TeO_4 + 2H_2O$). It is a diprotic acid with $K_{a_1} = 2 \times 10^{-8}$ and $K_{a_2} = 1 \times 10^{-11}$. Calculate the concentrations of H^+, $H_5TeO_6^-$, and $H_4TeO_6^{2-}$ in a 0.25 *M* solution of H_6TeO_6. What is the pH of the solution?

OH ***17.106** Calculate the concentrations of all of the solute species involved in the equilibria in a 2.0 *M* solution of H_3PO_4. Calculate the pH of the solution.

***17.107** What is the pH of a 0.25 *M* solution of arsenic acid, H_3AsO_4? In this solution, what are the concentrations of $H_2AsO_4^-$ and $HAsO_4^{2-}$?

***17.108** Phosphorous acid, H_3PO_3, is actually a diprotic acid for which $K_{a_1} = 5.0 \times 10^{-2}$ and $K_{a_2} = 2.0 \times 10^{-7}$. What are the values of $[H^+]$, $[H_2PO_3^-]$, and $[HPO_3^{2-}]$ in a 1.0 *M* solution of H_3PO_3? What is the pH of the solution?

17.109 What is the pH of a 0.20 *M* solution of oxalic acid, $H_2C_2O_4$?

Solutions of Salts of Polyprotic Acids

***17.110** Calculate the pH of 0.24 *M* Na_2SO_3. What are the concentrations of all ions and H_2SO_3 in the solution?

17.111 Calculate the pH of 0.33 *M* K_2CO_3. What are the concentrations of all ions and H_2CO_3 in the solution?

OH **17.112** Sodium citrate, $Na_3C_6H_5O_7$, is used as an anticoagulant in the collection of blood. What is the pH of a 0.10 *M* solution of this salt?

17.113 What is the pH of a 0.25 *M* solution of sodium oxalate, $Na_2C_2O_4$?

***17.114** What is the pH of a 0.50 *M* solution of Na_3PO_4? In this solution, what are the concentrations of HPO_4^{2-}, $H_2PO_4^-$, and H_3PO_4?

17.115 The pH of a 0.10 *M* Na_2CO_3 solution is adjusted to 12.00 using a strong base. What is the concentration of HCO_3^- in this solution?

Acid–Base Titrations

17.116 When 50.0 mL of 0.050 *M* formic acid, $HCHO_2$, is titrated with 0.050 *M* sodium hydroxide, what is the pH at the equivalence point? (Be sure to take into account the change in volume during the titration.) Select a good indicator for this titration from Table 17.7.

17.117 When 25 mL of 0.12 *M* aqueous ammonia is titrated with 0.12 *M* hydrobromic acid, what is the pH at the equivalence point? Select a good indicator for this titration from Table 17.7.

***17.118** What is the pH of a solution prepared by mixing 25.0 mL of 0.180 *M* $HC_2H_3O_2$ with 40.0 mL of 0.250 *M* NaOH?

***17.119** What is the pH of a solution prepared by mixing exactly 25.0 mL of 0.200 *M* $HC_2H_3O_2$ with 15.0 mL of 0.400 *M* KOH?

***17.120** For the titration of 75.00 mL of 0.1000 *M* acetic acid with 0.1000 *M* NaOH, calculate the pH **(a)** before the addition of any NaOH solution, **(b)** after 25.00 mL of the base has been added, **(c)** after half of the $HC_2H_3O_2$ has been neutralized, and **(d)** at the equivalence point.

***17.121** For the titration of 50.00 mL of 0.1000 *M* ammonia with 0.1000 *M* HCl, calculate the pH **(a)** before the addition of any HCl solution, **(b)** after 20.00 mL of the acid has been added, **(c)** after half of the NH_3 has been neutralized, and **(d)** at the equivalence point.

Additional Exercises

***17.122** Calculate the percentage ionization of acetic acid in solutions having concentrations of 1.0 *M*, 0.10 *M*, and 0.010 *M*. How does the percentage ionization of a weak acid change as the acid becomes more dilute?

17.123 What is the pH of a solution that is 0.100 *M* in HCl and also 0.125 *M* in $HC_2H_3O_2$? What is the concentration of acetate ion in this solution?

17.124 A solution is prepared by mixing 325 mL of 0.500 *M* NH_3 and 175 mL of 0.500 *M* HCl. Assuming that the volumes are additive, what is the pH of the resulting mixture?

***17.125** A solution is prepared by dissolving 15.0 g of pure $HC_2H_3O_2$ and 25.0 g of $NaC_2H_3O_2$ in 775 mL of solution (the final volume). **(a)** What is the pH of the solution? **(b)** What would the pH of the solution be if 25.0 mL of 0.250 *M* NaOH were added? **(c)** What would the pH be if 25.0 mL of 0.40 *M* HCl were added to the original 775 mL of buffer solution?

***17.126** For an experiment involving what happens to the growth of a particular fungus in a slightly acidic medium, a biochemist needs 255 mL of an acetate buffer with a pH of 5.12. The buffer solution has to be able to hold the pH to within ±0.10 pH unit of 5.12 even if 0.0100 mol of NaOH or 0.0100 mol of HCl enters the solution.

(a) What is the minimum number of grams of acetic acid and of sodium acetate dihydrate that must be used to prepare the buffer?

(b) Describe the buffer by giving its molarity in acetic acid and its molarity in sodium acetate.

(c) What is the pH of an unbuffered solution made by adding 0.0100 mol of NaOH to 255 mL of pure water?

(d) What is the pH of an unbuffered solution made by adding 0.0100 mol of HCl to 255 mL of pure water?

***17.127** Predict whether the pH of 0.120 *M* NH_4CN is greater than, less than, or equal to 7.00. Give your reasons.

***17.128** What is the pH of a 4.5×10^{-2} *M* solution of ammonium acetate, $NH_4C_2H_3O_2$?

***17.129** How many milliliters of ammonia gas measured at 25.2 °C and 745 torr must be dissolved in 0.250 L of 0.050 *M* HNO_3 to give a solution with a pH of 9.26?

17.130 $HClO_4$ is a stronger proton donor than HNO_3, but in water both acids appear to be of equal strength; they are both 100% ionized. Why is this so? What solvent property would be necessary in order to distinguish between the acidities of these two Brønsted acids?

17.131 The hydrogen sulfate ion, HSO_4^-, is a moderately strong Brønsted acid with a K_a of 1.2×10^{-2}.

(a) Write the chemical equation for the ionization of the acid and give the appropriate K_a expression.

(b) What is the value of $[H^+]$ in 0.010 *M* HSO_4^- (furnished by the salt, $NaHSO_4$)? Do NOT make simplifying assumptions; use the quadratic equation.

(c) What is the calculated $[H^+]$ in 0.010 M HSO_4^-, obtained by using the usual simplifying assumption?

(d) How much error is introduced by incorrectly using the simplifying assumption?

17.132 Some people who take megadoses of ascorbic acid will drink a solution containing as much as 6.0 g of ascorbic acid dissolved in a glass of water. Assuming the volume to be 0.250 L, calculate the pH of this solution.

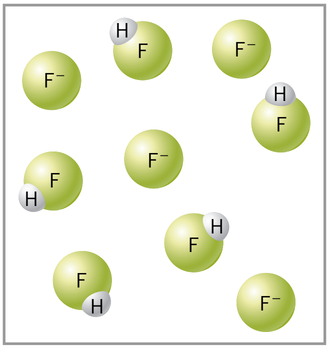
17.133 For the titration of 25.00 mL of 0.1000 M HCl with 0.1000 M NaOH, calculate the pH of the reaction mixture after each of the following total volumes of base have been added to the original solution. (Remember to take into account the change in total volume.) Construct a graph showing the titration curve for this experiment.

(a) 0 mL **(d)** 24.99 mL **(g)** 25.10 mL

(b) 10.00 mL **(e)** 25.00 mL **(h)** 26.00 mL

(c) 24.90 mL **(f)** 25.01 mL **(i)** 50.00 mL

17.134 Below is a diagram illustrating a mixture HF and F^- in an aqueous solution. For this mixture, does pH equal pK_a for HF? Explain. Describe how the number of HF molecules and F^- ions will change after three OH^- ions are added. How will the number of HF and F^- change if two H^+ ions are added? Explain your answers by using chemical equations.



Multi-Concept Problems

17.135 How many milliliters of 0.10 M NaOH must be added to 0.200 L of 0.010 M HCl to give a mixture with a pH of 3.00?

17.136 Milk of magnesia is a suspension of magnesium hydroxide in water. Although $Mg(OH)_2$ is relatively insoluble, a small amount does dissolve in the water, which makes the mixture slightly basic and gives it a pH of 10.08. How many grams of $Mg(OH)_2$ are actually dissolved in 2.0 tablespoons of milk of magnesia?

17.137 How many milliliters of 0.0100 M KOH are needed to completely neutralize the HCl in 325 mL of a hydrochloric acid solution that has a pH of 2.25?

17.138 It was found that 25.20 mL of an HNO_3 solution are needed to react completely with 30.0 mL of a LiOH solution that has a pH of 12.05. What is the molarity of the HNO_3 solution?

***17.139** Suppose 38.0 mL of 0.000200 M HCl is added to 40.0 mL of 0.000180 M NaOH. What will be the pH of the final mixture?

***17.140** Suppose 10.0 mL of HCl gas at 25 °C and 734 torr is bubbled into 257 mL of pure water. What will be the pH of the resulting solution, assuming all the HCl dissolves in the water?

***17.141** Suppose the HCl described in the preceding problem is bubbled into 20.00 L of a solution of NaOH that has a pH of 10.50. What will the pH of the resulting solution be?

***17.142** What is the approximate freezing point of a 0.50 M solution of dichloroacetic acid, $HC_2HO_2Cl_2$ ($K_a = 5.0 \times 10^{-2}$)? Assume the density of the solution is 1.0 g/mL.

Exercises in Critical Thinking

17.143 What happens to the pH of a solution as it is heated? Does that mean that the autoionization of water is exothermic or endothermic?

17.144 Can the pH of a solution ever have a negative value? Give an example of a situation where the pH has a negative value.

***17.145** In simplifying our calculations, we were satisfied with a maximum error of 5% in the concentration of hydronium ions when we compare the value calculated from the quadratic formula to the value obtained using simplifying assumptions. What does an error of 5% in hydrogen ion concentration mean in terms of pH? Is the pH error the same for a $1.0 \times 10^{-3}\ M\ H^+$ solution as it is for a $5.0 \times 10^{-6}\ M$ solution?

17.146 In the 1950s it was discovered that lakes in the northeastern United States had declining fish populations due to increased acidity. In order to address the problem of lake acidification, make a list of what you need to know in order to start addressing the problem.

17.147 Where are buffers found in everyday consumer products? Propose reasons why a manufacturer would use a buffer in a given product of your choice.

17.148 Why must the acid used for a buffer have a $\mathrm{p}K_\mathrm{a}$ within one pH unit of the pH of the buffer? What happens if that condition is not met?

17.149 What conjugate acid–base pairs are used to buffer **(a)** over-the-counter drugs, **(b)** foods, **(c)** cosmetics, and **(d)** shampoos?

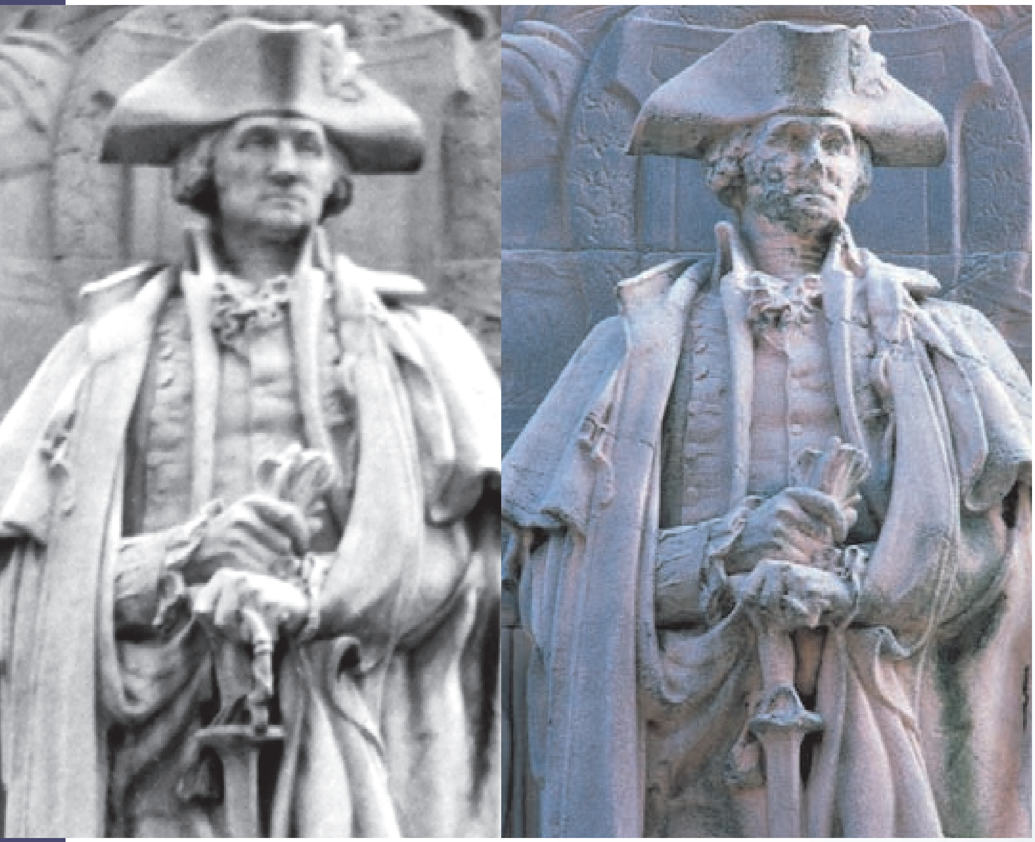
17.150 Your blood at 37 °C needs to be maintained within a narrow pH range of 7.35 to 7.45 to maintain optimal health. What possible conjugate acid–base pairs are present in blood that can buffer the blood and keep it within this range?

17.151 Develop a list of the uses of phosphoric acid in various consumer products.

17.152 Investigate the salts of phosphoric acid (i.e., those that contain $H_2PO_4^-$, HPO_4^{2-}, and PO_4^{3-}) to find out how they are used in consumer products.

17.153 What would our pH scale look like if Arrhenius decided that $\mathrm{pH} = -\ln\,[H^+]$? What would the pH of a neutral solution be?

18 Solubility and Simultaneous Equilibria



Chapter Outline

18.1 | Equilibria in Solutions of Slightly Soluble Neutral Salts

18.2 | Equilibria in Solutions of Metal Oxides and Sulfides

18.3 | Selective Precipitation

18.4 | Equilibria Involving Complex Ions

18.5 | Complexation and Solubility

Many beautiful statues that have graced New York City are slowly eroding away. This statue was carved from limestone, which is composed largely of calcium carbonate. Calcium carbonate is insoluble in water, but the solubility of it increases with increasing acidity. As the rain in America became more acidic in the past century, these statues have begun to diappear. In this chapter, we will discuss the solubility equilibria of "insoluble" salts such as calcium carbonate, and how these equilibria can be disrupted by acids and bases. © 1994 NYC Parks Photo Archive/Fundamental Photographs; © 1994 Kristen Brochmann/Fundamental Photographs.

This Chapter in Context

In the preceding chapters you learned how the principles of equilibrium can be applied to aqueous solutions of acids and bases. In this chapter we extend these principles to aqueous reactions that involve the formation and dissolving of precipitates (a topic we introduced in Chapter 5). Many such reactions are common in the world around us. For example, groundwater rich in carbon dioxide dissolves deposits of calcium carbonate, producing vast underground caverns, and as the remaining calcium-containing solution gradually evaporates, stalactites and stalagmites form. Within living organisms, precipitation reactions form the hard calcium carbonate shells of clams, oysters, and coral, as well as the unwanted calcium oxalate and calcium phosphate deposits we call kidney stones. Also, dilute acids in our mouths promote the dissolving of tooth enamel, which is composed of a mineral made up of calcium phosphate and calcium hydroxide.

In this chapter you will learn how we can calculate the solubilities of "insoluble" salts in water and in other solutions, and how the formation of substances called complex ions can affect solubilities. The concepts we develop here can tell us when precipitates will form and when they will dissolve, and we can use these in a practical lab setting in the separation of metal ions for chemical analysis.

18.1 | Equilibria in Solutions of Slightly Soluble Neutral Salts

Solubility Product Constant, K_{sp}

None of the salts we described in Chapter 5 as being insoluble are *totally* insoluble. For example, the solubility rules tell us that AgCl is "insoluble," but if some solid AgCl is placed in water, a very small amount does dissolve. Once the solution has become saturated, the following equilibrium is established between the undissolved AgCl and its ions in the solution:

$$\mathrm{AgCl}(s) \rightleftharpoons \mathrm{Ag}^+(aq) + \mathrm{Cl}^-(aq)$$

(In a saturated solution of AgCl)

■ Recall that when salts go into solution, they dissociate essentially completely, so the equilibrium is between the solid and the ions that are in the solution.

This is a heterogeneous equilibrium because it involves a solid reactant (AgCl) in equilibrium with ions in aqueous solution. Using the procedure developed in Section 15.4 (page 706), we write the equilibrium law as shown in Equation 18.1, omitting the solid from the mass action expression.

$$[\mathrm{Ag}^+][\mathrm{Cl}^-] = K_{sp} \tag{18.1}$$

The equilibrium constant, K_{sp}, is called the **solubility product constant** (because the system is a *solubility* equilibrium and the *constant* equals a *product* of ion concentrations).

TOOLS

Solubility product constant, K_{sp}

It's important that you understand the distinction between solubility and solubility product. The *solubility* of a salt is the amount of the salt that dissolves in a given amount of solvent to give a saturated solution. The *solubility product* is the product of the molar concentrations of the ions in the saturated solution, raised to appropriate powers (see below).

The solubilities of salts change with temperature, so a value of K_{sp} applies only at the temperature at which it was determined. Some typical K_{sp} values are listed in Table 18.1 and in Appendix C.

Table 18.1 Solubility Product Constants[a]

Type	Salt		Ions of Salt	K_{sp} (25 °C)
Halides	CaF_2	$\rightleftharpoons$	$Ca^{2+} + 2F^-$	3.4×10^{-11}
	PbF_2	$\rightleftharpoons$	$Pb^{2+} + 2F^-$	3.3×10^{-8}
	$AgCl$	$\rightleftharpoons$	$Ag^+ + Cl^-$	1.8×10^{-10}
	$AgBr$	$\rightleftharpoons$	$Ag^+ + Br^-$	5.4×10^{-13}
	AgI	$\rightleftharpoons$	$Ag^+ + I^-$	8.5×10^{-17}
	$PbCl_2$	$\rightleftharpoons$	$Pb^{2+} + 2Cl^-$	1.7×10^{-5}
	$PbBr_2$	$\rightleftharpoons$	$Pb^{2+} + 2Br^-$	6.6×10^{-6}
	PbI_2	$\rightleftharpoons$	$Pb^{2+} + 2I^-$	9.8×10^{-9}
Hydroxides	$Al(OH)_3$	$\rightleftharpoons$	$Al^{3+} + 3OH^-$	3×10^{-34} (b)
	$Ca(OH)_2$	$\rightleftharpoons$	$Ca^{2+} + 2OH^-$	5.0×10^{-6}
	$Fe(OH)_2$	$\rightleftharpoons$	$Fe^{2+} + 2OH^-$	4.9×10^{-17}
	$Fe(OH)_3$	$\rightleftharpoons$	$Fe^{3+} + 3OH^-$	2.8×10^{-39}
	$Mg(OH)_2$	$\rightleftharpoons$	$Mg^{2+} + 2OH^-$	5.6×10^{-12}
	$Zn(OH)_2$	$\rightleftharpoons$	$Zn^{2+} + 2OH^-$	3×10^{-17} (c)
Carbonates	Ag_2CO_3	$\rightleftharpoons$	$2Ag^+ + CO_3^{2-}$	8.5×10^{-12}
	$MgCO_3$	$\rightleftharpoons$	$Mg^{2+} + CO_3^{2-}$	6.8×10^{-8}
	$CaCO_3$	$\rightleftharpoons$	$Ca^{2+} + CO_3^{2-}$	3.4×10^{-9} (d)
	$SrCO_3$	$\rightleftharpoons$	$Sr^{2+} + CO_3^{2-}$	5.6×10^{-10}
	$BaCO_3$	$\rightleftharpoons$	$Ba^{2+} + CO_3^{2-}$	2.6×10^{-9}
	$CoCO_3$	$\rightleftharpoons$	$Co^{2+} + CO_3^{2-}$	1.0×10^{-10}
	$NiCO_3$	$\rightleftharpoons$	$Ni^{2+} + CO_3^{2-}$	1.4×10^{-7}
	$ZnCO_3$	$\rightleftharpoons$	$Zn^{2+} + CO_3^{2-}$	1.5×10^{-10}
Chromates	Ag_2CrO_4	$\rightleftharpoons$	$2Ag^+ + CrO_4^{2-}$	1.1×10^{-12}
	$PbCrO_4$	$\rightleftharpoons$	$Pb^{2+} + CrO_4^{2-}$	1.8×10^{-14} (e)
Sulfates	$CaSO_4$	$\rightleftharpoons$	$Ca^{2+} + SO_4^{2-}$	4.9×10^{-5}
	$SrSO_4$	$\rightleftharpoons$	$Sr^{2+} + SO_4^{2-}$	3.4×10^{-7}
	$BaSO_4$	$\rightleftharpoons$	$Ba^{2+} + SO_4^{2-}$	1.1×10^{-10}
	$PbSO_4$	$\rightleftharpoons$	$Pb^{2+} + SO_4^{2-}$	2.5×10^{-8}
Oxalates	CaC_2O_4	$\rightleftharpoons$	$Ca^{2+} + C_2O_4^{2-}$	2.3×10^{-9}
	MgC_2O_4	$\rightleftharpoons$	$Mg^{2+} + C_2O_4^{2-}$	4.8×10^{-6}
	BaC_2O_4	$\rightleftharpoons$	$Ba^{2+} + C_2O_4^{2-}$	1.2×10^{-7}
	FeC_2O_4	$\rightleftharpoons$	$Fe^{2+} + C_2O_4^{2-}$	2.1×10^{-7}
	PbC_2O_4	$\rightleftharpoons$	$Pb^{2+} + C_2O_4^{2-}$	2.7×10^{-11}

Ion Product, the Reaction Quotient for Slightly Soluble Salts

In preceding chapters we described the value of the mass action expression as the reaction quotient, Q. For simple solubility equilibria like those discussed in this section, the mass action expression is a product of ion concentrations raised to appropriate powers, so Q is often called the **ion product** of the salt. Thus, for AgCl,

$$\text{ion product} = [Ag^+][Cl^-] = Q$$

At any dilution of a salt throughout the range of possibilities for an *unsaturated* solution, there will be varying values for the ion concentrations and, therefore, for Q. However, Q acquires a constant value, K_{sp}, in a *saturated* solution. When a solution is less than saturated, the value of Q is less than K_{sp}. Thus, we can use the numerical value of Q for a given solution as a test for saturation by comparing it to the value of K_{sp}.

Many salts produce more than one of a given ion per formula unit when they dissociate, and this introduces exponents into the ion product expression. For example, when silver chromate, Ag_2CrO_4, precipitates (Figure 18.1), it enters into the following solubility equilibrium:

$$Ag_2CrO_4(s) \rightleftharpoons 2Ag^+(aq) + CrO_4^{2-}(aq)$$

The equilibrium law is obtained following the procedure we developed in Chapter 15, using coefficients as exponents in the mass action expression:

$$[Ag^+]^2[CrO_4^{2-}] = K_{sp}$$

Thus, the ion product contains the ion concentrations raised to powers equal to the number of ions released per formula unit. This means that to obtain the correct ion product expression you have to know the formulas of the ions that make up the salt. In other words, you have to realize that Ag_2CrO_4 is composed of $2Ag^+$ and the polyatomic anion CrO_4^{2-}. If necessary, review the list of polyatomic ions in Table 3.5 on page 84.

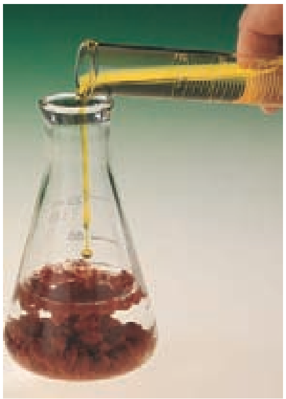

Figure 18.1 | **Silver chromate.** When sodium chromate is added to a solution of silver nitrate, deep red-brown "insoluble" silver chromate, Ag_2CrO_4, precipitates. *(Michael Watson)*

Practice Exercises

18.1 | Write the equation for the equilibrium involved in the solubility of barium phosphate, $Ba_3(PO_4)_2$, and write the equilibrium law corresponding to K_{sp}. (*Hint*: Remember that it's a heterogeneous equilibrium.)

18.2 | What are the ion product expressions for the following salts? (a) calcium oxalate, (b) silver sulfate.

Determining K_{sp} from Molar Solubilities

One way to determine the value of K_{sp} for a salt is to measure its solubility—that is, how much of the salt is required to give a saturated solution in a specified amount of solution. It is useful to express this as the **molar solubility**, which equals *the number of moles of salt dissolved in one liter of its **saturated solution.*** The molar solubility can be used to calculate the K_{sp} under the assumption that all of the salt that dissolves is 100% dissociated into the ions implied in the salt's formula.[1]

TOOLS
Molar solubility

One note here about calculations involving solubility products. Many of the calculations we will carry out include changes in concentration, and the use of concentration tables, as introduced in Chapter 15, will help organize our thoughts and make the calculations easier. If used properly, the concentration tables lay out all of the values for the concentrations and changes that occur during the solubility process. This is illustrated in Example 18.1.

TOOLS
Concentration tables

Example 18.1

Calculating K_{sp} from Solubility Data

Silver bromide, AgBr, is the light-sensitive compound used in nearly all photographic film. The solubility of AgBr in water was measured to be 1.3×10^{-4} g L^{-1} at 25 °C. Calculate K_{sp} for AgBr at this temperature.

---

[1] This assumption works reasonably well for slightly soluble salts made up of singly charged ions, like silver bromide. For simplicity, and to illustrate the nature of calculations involving solubility equilibria, we will work on the assumption that *all* salts behave as though they are 100% dissociated. This is not entirely true, especially for salts of multiply charged ions, so the accuracy of our calculations is limited. We discussed the reasons for the incomplete dissociation of salts in Section 13.7.

Analysis: For any question about the solubility of a slightly soluble salt, we need to start with the balanced chemical equation, from which we construct the equation for the solubility product constant, K_{sp}.

In order to determine the K_{sp}, we will need the molar solubilities of the ions that are in solution. We are given a solubility of AgBr in g L^{-1}, so we will have to convert the concentration of each ion to mol L^{-1}. We also need to keep track of how many ions AgBr gives in solution, which we can get from the stoichiometric ratio in the balanced chemical equation.

Using the concentrations of the ions in solution, we can calculate the K_{sp} using the equilibrium equation.

Assembling the Tools: The first tool that we will need is the equation for the solubility product constant, K_{sp}, which we derived from the balanced chemical equation:

$$\text{AgBr}(s) \rightleftharpoons \text{Ag}^+(aq) + \text{Br}^-(aq) \qquad K_{sp} = [\text{Ag}^+][\text{Br}^-]$$

To calculate K_{sp}, we need the concentrations of the ions expressed in moles per liter, so we will use the tools from Chapter 4 to convert the mass to moles in order to convert 1.3×10^{-4} g L^{-1} to moles per liter.

For many problems dealing with solubility, the concentration table is a useful tool. We introduced this tool in Chapter 15, and it is helpful to review its use again here. The first row, the initial concentration row, is where we put the concentrations of ions before any reaction occurs, and in this case, that means the concentrations before any of the solid dissolves. The second row is for the changes in concentration, which, for this example, will be the concentration of ions in moles per liter. The final row, the equilibrium concentration row, is the sum of the first two rows.

The equilibrium concentrations are now used to calculate the value of K_{sp} by applying the concentrations to the K_{sp} equation.

Solution: We need to start with the balanced chemical equation and the expression for the solubility product constant,

$$\text{AgBr}(s) \rightleftharpoons \text{Ag}^+(aq) + \text{Br}^-(aq)$$
$$K_{sp} = [\text{Ag}^+][\text{Br}^-]$$

Then we calculate the number of moles of AgBr dissolved per liter:

$$\text{molar solubility} = \frac{1.3 \times 10^{-4}\ \cancel{\text{g AgBr}}}{1.00\ \text{L soln}} \times \frac{1.00\ \text{mol AgBr}}{187.77\ \cancel{\text{g AgBr}}} = 6.9 \times 10^{-7}\ \text{mol L}^{-1}$$

Now we can begin to set up the concentration table, which is shown below. Notice first that there are no entries in the "reactant" column. This is because AgBr is a solid and doesn't appear in the mass action expression.

In setting up the table, it is helpful if we imagine the formation of the saturated solution to occur stepwise. Once we have the equilibrium ion concentrations, we substitute them into the ion product expression to calculate K_{sp}.

Initial Concentrations

In the first row under the formulas of the ions—the initial concentration row—we enter the initial concentrations of Ag^+ and Br^-. *Remember, these are the concentrations of the ions present in the solvent before any of the AgBr dissolves.* In this case, the solvent is pure water. Neither Ag^+ nor Br^- are present in pure water, so we set the initial concentrations equal to zero. However, if the solvent had contained a solute that is a source of one of the ions in the equilibrium, we would have used its concentration as the initial concentration of that ion.

Changes in Concentrations

In the "change" row, we enter data on how the concentrations of the $\text{Ag}^+(aq)$ and $\text{Br}^-(aq)$ change when the AgBr dissolves. Because dissolving the salt always increases these concentrations, these entries are always positive. They are also related to each other by the stoichiometry of the dissociation reaction. Thus, when AgBr dissolves, Ag^+ and Br^- ions are released in a 1:1 ratio. So, when 6.9×10^{-7} mol of AgBr dissolves (per liter), 6.9×10^{-7} mol of Ag^+ ion and 6.9×10^{-7} mol of Br^- ion go into solution. The concentrations of these species thus *change* (increase) by these amounts.

Equilibrium Concentrations

As usual, we obtain the equilibrium values by adding the "initial concentrations" to the "changes."

	$AgBr(s)$	$\rightleftharpoons$	$Ag^+(aq)$	+	$Br^-(aq)$
Initial concentrations (*M*)	No entries in this column		0		0
Changes in concentrations when AgBr dissolves (*M*)			$+6.9 \times 10^{-7}$		$+6.9 \times 10^{-7}$
Equilibrium concentrations (*M*)			6.9×10^{-7}		6.9×10^{-7}

■ There are no entries in the column under $AgBr(s)$ because this substance does not appear in the K_{sp} expression.

We now substitute the equilibrium ion concentrations into the K_{sp} expression.

$$\begin{aligned} K_{sp} &= [Ag^+][Br^-] \\ &= (6.9 \times 10^{-7})(6.9 \times 10^{-7}) \\ &= 4.8 \times 10^{-13} \end{aligned}$$

The K_{sp} of AgBr is thus calculated to be 4.8×10^{-13} at 25 °C.

■ **Is the Answer Reasonable?** We can check this problem by approximating the molar mass of AgBr following the calculations, and by checking our reasoning. We've divided 1.3×10^{-4} by a number that's approximately 200, which would give a value of about 6.5×10^{-7}, so our molar solubility seems reasonable. (Also, AgBr has a very low solubility in water, so we expect the molar solubility to be very small.) The reasoning involved in the change row also makes sense; the number of moles of ions formed per liter must each equal the number of moles of AgBr that dissolve. Finally, if we round 6.9×10^{-7} to 7×10^{-7} and square it, we obtain $49 \times 10^{-14} = 4.9 \times 10^{-13}$. Our answer of 4.8×10^{-13}, therefore, seems to be okay.

■ The K_{sp} we calculated from the solubility data here differs by only 4% from the value in Table 18.1.

Example 18.2

Calculating K_{sp} from Molar Solubility Data

The molar solubility of silver chromate, Ag_2CrO_4, in water is 6.7×10^{-5} mol L^{-1} at 25 °C. What is K_{sp} for Ag_2CrO_4?

■ **Analysis:** This problem is very similar to Example 18.1, except that the ions are not in a one-to-one ratio. In this case, when Ag_2CrO_4 dissolves, it produces two Ag^+ for each Ag_2CrO_4.

■ **Assembling the Tools:** The tools we will need for this problem are the same as the tools in Example 18.1, except we are given the solubility in mol L^{-1}, so we do not have to convert from grams to moles. We will need the balanced equilibrium equation and the K_{sp} expression:

$$Ag_2CrO_4(s) \rightleftharpoons 2Ag^+(aq) + CrO_4^{2-}(aq)$$

$$K_{sp} = [Ag^+]^2[CrO_4^{2-}]$$

We will also use the concentration table as our tool for analyzing the concentrations. We will use it in the same fashion as we did in Example 18.1. However, we need to be careful with the ions—there will be two moles of silver ions for each mole of Ag_2CrO_4—so when we calculate the moles of silver dissolved, we have to use the mole ratio of 2 mol Ag^+ to 1 mol Ag_2CrO_4.

Solution: For the balanced equilibrium equation and K_{sp} expression, we have

$$\mathrm{Ag_2CrO_4}(s) \rightleftharpoons 2\mathrm{Ag^+}(aq) + \mathrm{CrO_4^{2-}}(aq)$$
$$K_{sp} = [\mathrm{Ag^+}]^2[\mathrm{CrO_4^{2-}}]$$

The solute is pure water, so neither Ag^+ nor CrO_4^{2-} is present before the salt dissolves; their initial concentrations are zero. For the "change" row, we have to be careful to take into account the formula of the salt. In a liter of water, when 6.7×10^{-5} mol of Ag_2CrO_4 dissolves, we obtain 6.7×10^{-5} mol of CrO_4^{2-} and $2 \times (6.7 \times 10^{-5}$ mol) of Ag^+. With this information, we can fill in the "initial" and "change" rows. Then, we can add the "initial" and "change" rows together to arrive at the equilibrium concentrations.

	$Ag_2CrO_4(s)$ $\rightleftharpoons$	$2Ag^+(aq)$	+	$CrO_4^{2-}(aq)$
Initial concentrations (*M*)		0		0
Changes in concentrations when Ag_2CrO_4 dissolves (*M*)		$+[2 \times (6.7 \times 10^{-5})]$ $= +1.3 \times 10^{-4}$		$+6.7 \times 10^{-5}$
Equilibrium concentrations (*M*)		1.3×10^{-4}		6.7×10^{-5}

Substituting the equilibrium concentrations into the mass action expression for K_{sp} gives

$$\begin{aligned} K_{sp} &= (1.3 \times 10^{-4})^2(6.7 \times 10^{-5}) \\ &= 1.1 \times 10^{-12} \end{aligned}$$

So the K_{sp} of Ag_2CrO_4 at 25 °C is calculated to be 1.1×10^{-12}.

Is the Answer Reasonable? The critical link in solving the problem correctly is placing the correct quantities in the "initial" and "change" rows. The Ag_2CrO_4 is dissolved in water, so the initial concentrations of the ions must be zero; these entries are okay. For the "changes," it's important to remember that the quantities are related to each other by the coefficients in the balanced chemical equation. That means the change for Ag^+ must be twice as large as the change for CrO_4^{2-}. Studying the table, we see that we've done this correctly. We can also see that we've added the "change" to the "initial" values correctly, and that we've performed the proper arithmetic in evaluating the mass action expression.

Practice Exercises

18.3 | The solubility of thallium(I) iodide, TlI, in water at 20 °C is 5.9×10^{-3} g L^{-1}. Using this fact, calculate K_{sp} for TlI on the assumption that it is 100% dissociated in the solution. (*Hint*: What is the molar solubility of TlI?)

18.4 | One liter of water will dissolve 2.15×10^{-3} mol of PbF_2 at 25 °C. Calculate the value of K_{sp} for PbF_2.

18.5 | The slightly soluble salt, Ag_3PO_4, has a solubility of 7.5×10^{-3} g L^{-1} at 25 °C. Assuming that the ions completely dissociate in solution, calculate the value of K_{sp} for Ag_3PO_4.

Determining Molar Solubility from K_{sp}

Besides calculating K_{sp} from solubility information, we can also compute solubilities from values of K_{sp}. Examples 18.3 and 18.4 illustrate the calculations.[2]

---

[2] As noted earlier, these calculations ignore the fact that the salt that dissolves is not truly 100% dissociated into the ions implied in the salt's formula. This is particularly a problem with the salts of multiply charged ions, so the solubilities of such salts, when calculated from their K_{sp} values, must be taken as rough estimates. In fact, many calculations involving K_{sp} give values that are merely estimates.

Example 18.3
Calculating Molar Solubility from K_{sp}

What is the molar solubility of AgCl in pure water at 25 °C?

■ **Analysis:** To solve the problem, we're going to need a balanced chemical equation for the solubility equilibrium, the equilibrium law (K_{sp} expression), and the value of K_{sp}, which we can obtain from Table 18.1. We will also need to set up a concentration table, but this time the solubility is unknown, so this will affect the quantities we enter into the change row.

■ **Assembling the Tools:** The relevant equations to solve this problem are

$$\mathrm{AgCl}(s) \rightleftharpoons \mathrm{Ag}^+(aq) + \mathrm{Cl}^-(aq) \qquad K_{sp} = [\mathrm{Ag}^+][\mathrm{Cl}^-] = 1.8 \times 10^{-10}$$

With these equations, we can build a concentration table. First, we see that the solvent is pure water, so neither Ag^+ nor Cl^- is present in solution at the start; their *initial* concentrations are zero.

Next, we turn to the "change" row. If we knew what the changes were, we could calculate the equilibrium concentrations and figure out the molar solubility. But we don't know the changes, so we will have to find them algebraically. To do this, *we will define our unknown x as the molar solubility of the salt*—that is, the number of moles of AgCl that dissolves in one liter. Because 1 mol of AgCl yields 1 mol Ag^+ and 1 mol Cl^-, the concentration of each of these ions increases by x (i.e., their changes are each $+x$).

■ **Solution:** Our concentration table is as follows:

$\mathrm{AgCl}(s) \rightleftharpoons$	$\mathrm{Ag}^+(aq)$	+	$\mathrm{Cl}^-(aq)$
Initial concentrations (M)	0		0
Changes in concentrations when AgCl dissolves (M)	$+x$		$+x$
Equilibrium concentrations (M)	x		x

■ By defining x as the molar solubility, the coefficients of x in the "change" row are the same as the coefficients of Ag^+ and Cl^- in the equation for the equilibrium.

We make the substitutions into the K_{sp} expression, using equilibrium quantities from the last row of the table:

$$(x)(x) = 1.8 \times 10^{-10}$$
$$x = 1.3 \times 10^{-5}$$

The calculated molar solubility of AgCl in water at 25 °C is 1.3×10^{-5} mol L^{-1}.

■ **Is the Answer Reasonable?** The solvent is water, so the initial concentrations are zero. If x is the molar solubility, then the changes in the concentrations of Ag^+ and Cl^- when the salt dissolves must also be equal to x. We can also check the algebra, which we've done correctly, so the answer seems to be okay.

Example 18.4
Calculating Molar Solubility from K_{sp}

Calculate the molar solubility of lead(II) iodide in water at 25 °C from its K_{sp}.

■ **Analysis:** The key to this problem is realizing that there are two iodide ions released for each lead(II) iodide. For this problem, we will need to start with $\mathrm{PbI_2}$, the formula for lead(II) iodide, so that we can set up the balanced chemical equation and the K_{sp} expression. Then, we will need to use a concentration table to find the molar solubilities of the lead(II) iodide.

A precipitate of yellow PbI_2 forms when the two colorless solutions, one with sodium iodide and the other of lead(II) nitrate, are mixed. *(Lawrence Migdale/Photo Researchers)*

Assembling the Tools: The tools are the same tools we used in Example 18.3, except that the first thing we need to do is determine the formula for lead(II) iodide, PbI_2, which is obtained from the rules of nomenclature in Chapter 3. We then use the equation for the equilibrium and the K_{sp} expression. We obtain K_{sp} from Table 18.1.

$$PbI_2(s) \rightleftharpoons Pb^{2+}(aq) + 2I^-(aq) \qquad K_{sp} = [Pb^{2+}][I^-]^2 = 9.8 \times 10^{-9}$$

For the concentration table, we can start with the solvent, water, and the initial concentrations of the ions, which are zero. As before, we will define x as the molar solubility of the salt. By doing this, the coefficients of x in the "change" row will be identical to the coefficients of the ions in the chemical equation. This assures us that the changes in the concentrations are in the correct mole ratio.

Solution: Here is the concentration table.

$PbI_2(s) \rightleftharpoons$	$Pb^{2+}(aq)$	+	$2I^-(aq)$
Initial concentrations (M)	0		0
Changes in concentrations when PbI_2 dissolves (M)	$+x$		$+2x$
Equilibrium concentrations (M)	x		$2x$

Substituting equilibrium quantities into the K_{sp} expression gives

$$\begin{aligned} K_{sp} = (x)(2x)^2 = 4x^3 &= 9.8 \times 10^{-9} \\ x^3 &= 2.5 \times 10^{-9} \\ x &= 1.3 \times 10^{-3} \end{aligned}$$

Thus, the molar solubility of PbI_2 in pure water is calculated to be 1.3×10^{-3} mol L^{-1}.

Is the Answer Reasonable? We check the entries in the table. The solvent is water, so the initial concentrations are equal to zero. By setting x equal to the moles per liter of PbI_2 that dissolves (i.e., the molar solubility), the coefficients x in the "change" row have to be the same as the coefficients of Pb^{2+} and Cl^- in the balanced chemical equation. The entries in the "change" row are okay. In performing the algebra, notice that when we square $2x$, we get $4x^2$. Multiplying $4x^2$ by x gives $4x^3$. After that, if our math is correct, the answer is correct.

Practice Exercises

18.6 | What is the calculated molar solubility in water at 25 °C of (a) AgBr and (b) Ag_2CO_3? (*Hint*: Review the algebra in Example 18.4.)

18.7 | Calculate the molar solubility of $Ca_3(PO_4)_2$ in water. Its K_{sp} is 2.1×10^{-33}.

The Common Ion Effect

Suppose that we stir some lead(II) chloride (a compound having a low solubility) with water long enough to establish the following equilibrium:

$$PbCl_2(s) \rightleftharpoons Pb^{2+}(aq) + 2Cl^-(aq)$$

If we now add a concentrated solution of a soluble lead compound, such as $Pb(NO_3)_2$, the increased concentration of Pb^{2+} in the $PbCl_2$ solution will drive the position of equilibrium to the left, causing some $PbCl_2$ to precipitate. The phenomenon is simply an application of Le Châtelier's principle, the net result being that $PbCl_2$ is less soluble in a solution that contains Pb^{2+} from another source than it is in pure water. The same effect is produced if a concentrated solution of a soluble chloride salt such as NaCl is added to the saturated $PbCl_2$ solution. The added Cl^- will drive the equilibrium to the left, reducing the amount of dissolved $PbCl_2$.

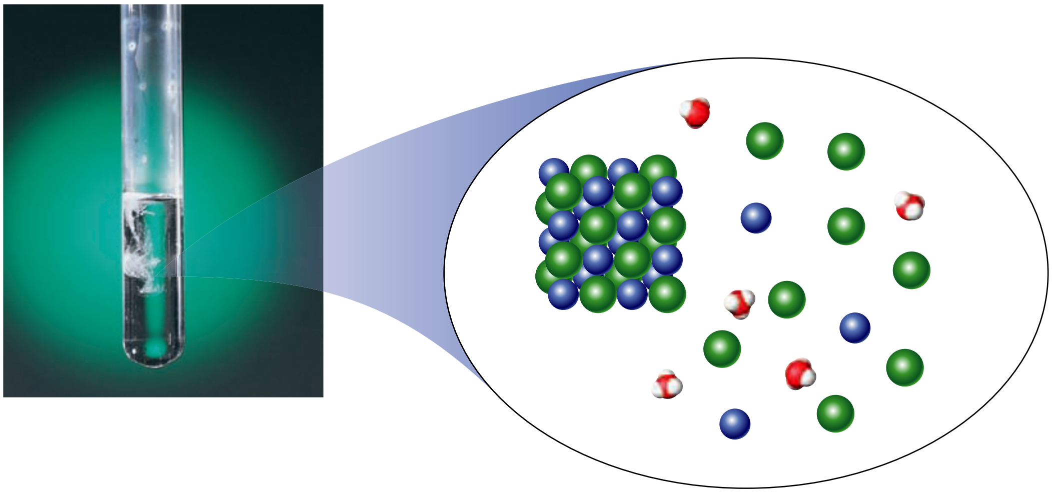

Figure 18.2 | **The common ion effect.** The test tube shown here initially held a saturated solution of NaCl, where the equilibrium, $NaCl(s) \rightleftharpoons Na^+(aq) + Cl^-(aq)$, had been established. Addition of a few drops of concentrated HCl, containing a high concentration of the common ion Cl^-, in green, forced the equilibrium to shift to the left. This caused some white crystals of solid NaCl to precipitate. *(Michael Watson)*

The phenomenon we just described is an example of the *common ion effect*, which we also described in Chapter 17. In this case, Pb^{2+} is the common ion when we add $Pb(NO_3)_2$ and Cl^- is the common ion when we add NaCl. Figure 18.2 shows how even a relatively soluble salt, NaCl, can be forced out of its saturated solution simply by adding concentrated hydrochloric acid, which serves as a source of the common ion, Cl^-. The common ion effect can dramatically lower the solubility of a salt, as Example 18.5 demonstrates.

Example 18.5
Calculations Involving the Common Ion Effect

What is the molar solubility of PbI_2 in a 0.10 *M* NaI solution?

Analysis: Because PbI_2 and NaI have the same ion in common, this is an example of a calculation involving the common ion effect. As usual, to solve the problem we're going to need a balanced chemical equation for the solubility equilibrium, the equilibrium law (i.e., the K_{sp} expression), and the value of K_{sp}, which is listed in Table 18.1. We will also need to set up a concentration table as in Example 18.4, but this time we have to take into account the solute already present in the solution.

Assembling the Tools: We begin with the balanced chemical equation for the equilibrium, the appropriate K_{sp} expression, and the value of K_{sp} obtained from Table 18.1:

$$PbI_2(s) \rightleftharpoons Pb^{2+}(aq) + 2I^-(aq) \qquad K_{sp} = [Pb^{2+}][I^-]^2 = 9.8 \times 10^{-9}$$

As before, we imagine that we are adding the PbI_2 to a solvent into which it dissolves. This time, however, the solvent isn't water; it's a solution of NaI, which contains one of the ions of the salt PbI_2. The NaI completely dissociates and yields 0.10 *M* Na^+ and 0.10 *M* I^-. The initial concentration of I^- is therefore 0.10 *M*.

Next, we let x be the molar solubility of PbI_2. When x mol of PbI_2 dissolves per liter, the concentration of Pb^{2+} changes by $+x$ and that of I^- by twice as much, or $+2x$. Finally, the equilibrium concentrations are obtained by summing the initial concentrations and the changes.

Solution: Here is the concentration table.

	$PbI_2(s) \rightleftharpoons$	$Pb^{2+}(aq)$	+	$2I^-(aq)$
Initial concentrations (M)		0		0.10
Changes in concentrations when PbI_2 dissolves (M)		$+x$		$+2x$
Equilibrium concentrations (M)		x		$0.10 + 2x$

Substituting equilibrium values into the K_{sp} expression gives

$$K_{sp} = [Pb^{2+}][I^-]^2 = (x)(0.10 + 2x)^2 = 9.8 \times 10^{-9}$$

Just a brief inspection reveals that solving this expression for x will be difficult if we cannot simplify the math. Fortunately, a simplification is possible, because the small value of K_{sp} for PbI_2 indicates that the salt has a very low solubility. This means very little of the salt will dissolve, so x (or even $2x$) will be quite small. Let's assume that $2x$ will be much smaller than 0.10. If this is so, then

$$0.10 + 2x \approx 0.10 \text{ (assuming } 2x \text{ is negligible compared to 0.10)}$$

Substituting 0.10 M for the I^- concentration gives

$$\begin{aligned} K_{sp} &= (x)(0.10)^2 = 9.8 \times 10^{-9} \\ x &= \frac{9.8 \times 10^{-9}}{(0.10)^2} \\ &= 9.8 \times 10^{-7}\ M \end{aligned}$$

Thus, the molar solubility of PbI_2 in 0.10 M NaI solution is calculated to be 9.8×10^{-7} M.

We should always check to see if our simplifying assumption is valid. Notice that $2x$, which equals 2.0×10^{-6}, is indeed vastly smaller than 0.10, just as we anticipated. (If we add 2.0×10^{-6} to 0.10 and round correctly, we obtain 0.10.)

Is the Answer Reasonable? First, we can check the entries in the concentration table. The initial concentrations come from the solvent, which contains no Pb^{2+} but does contain 0.10 M I^-. By letting x equal the molar solubility, the coefficients of x in the "change" row equal the coefficients in the balanced equation for the equilibrium. At this point, we have checked the concentration table. To check the answer, we can recalculate the K_{sp}.

Practice Exercises

18.8 | Calculate the molar solubility of AgI in a 0.20 M CaI_2 solution. Compare the answer to the calculated molar solubility of AgI in pure water. (*Hint*: What is the I^- concentration in 0.20 M CaI_2?)

18.9 | Calculate the molar solubility of $Fe(OH)_3$ in a solution where the OH^- concentration is initially 0.050 M. Assume the dissociation of $Fe(OH)_3$ is 100%.

READ THESE TWO PARAGRAPHS!

A Mistake to Avoid

The most common mistake that students make with problems like Example 18.5 is to use the coefficient of an ion in the solubility equilibrium at the wrong moment in the calculation. The coefficient of I^- in the PbI_2 equilibrium is 2. The mistake is to use this 2 to double the *initial* concentration of I^-; however, the *initial* concentration of I^- was provided not by PbI_2 but by NaI. When 0.10 mol of NaI dissociates, it gives 0.10 mol of I^-, not 2 × 0.10 mol. *The coefficients in the equation for the equilibrium are only used to obtain the quantities in the "change" row.*

To avoid mistakes, it is useful to always view the formation of the final solution as a two-step process. You begin with a solvent into which the "insoluble solid" will be placed. In some problems, the solvent may be pure water, in which case the initial concentrations of the ions will be zero—see Examples 18.1–18.4. In other problems, like Example 18.5, the solvent will be a *solution* that contains a common ion. When this is so, first decide what the concentration of the common ion is and enter this value into the "initial concentration" row of the table. Next, imagine that the solid is added to the solvent and a little of it dissolves. *The amount that dissolves is what gives the values in the "change" row.* These entries must be in the same ratio as the coefficients in the equilibrium, which is accomplished if we let *x* be the molar solubility of the salt. Then, the coefficients of *x* will be the same as the coefficients of the ions in the balanced chemical equation for the equilibrium.

In Example 18.4, we found that the molar solubility of PbI_2 in *pure* water was $1.3 \times 10^{-3}\ M$. In water that contains 0.10 *M* NaI (Example 18.5), the solubility of PbI_2 is $9.8 \times 10^{-7}\ M$, well over a thousand times smaller. As we said, the common ion effect often causes huge reductions in the solubilities of sparingly soluble compounds by shifting the equilibrium toward the formation of the solid.

Determining whether a Precipitate Will Form

If we know the anticipated concentrations of the ions of a salt in a solution, we can use the value of K_{sp} for the salt to predict whether or not a precipitate should form. This is because the computed value for *Q* (the ion product) can tell us whether a solution is unsaturated, saturated, or supersaturated. *For a precipitate of a salt to form, the solution must be supersaturated.*

If the solution is unsaturated, its ion concentrations are less than required for saturation, *Q* is less than K_{sp}, and no precipitate will form. For a saturated solution, we have *Q* equal to K_{sp}, and no precipitate will form. (If a precipitate were to form, the solution would become unsaturated and the precipitate would redissolve.) If the solution is supersaturated, the ion concentrations exceed those required for saturation and *Q* is larger than K_{sp}. Only in this last instance should we expect a precipitate to form so that *Q* will be reduced to the value of the K_{sp}. This can be summarized as follows:

Precipitate will form	$Q > K_{sp}$	(supersaturated)
No precipitate will form	$Q = K_{sp}$	(saturated)
	$Q < K_{sp}$	(unsaturated)

Predicting precipitation

Let's look at some sample calculations.

Example 18.6
Predicting whether a Precipitate Will Form

Suppose we want to prepare 0.500 L of a solution containing 0.0075 mol of NaCl and 0.075 mol of $Pb(NO_3)_2$. Knowing from the solubility rules that the chloride of Pb^{2+} is "insoluble," we are concerned that a precipitate of $PbCl_2$ might form. Will it?

■ **Analysis:** To find out whether a precipitate will form, we will have to compare the value of *Q*, computed using the data in the problem, with K_{sp}. Then, we can apply the criteria above. This also means that we have to write the correct ion product expression and we're going to have to calculate the molar concentrations of the Pb^{2+} and Cl^- ions in the solution.

■ **Assembling the Tools:** To calculate the value of *Q*, our tool is the appropriate ion product for $PbCl_2$, which we can obtain by writing the solubility equilibrium equation and the K_{sp} expression that applies to a saturated solution of $PbCl_2$:

$$PbCl_2(s) \rightleftharpoons Pb^{2+}(aq) + 2Cl^-(aq) \qquad K_{sp} = [Pb^{2+}][Cl^-]^2$$

From Table 18.1, $K_{sp} = 1.7 \times 10^{-5}$.

We also have to compute the molar concentrations of the ions. The definition of molarity provides the necessary tool, by taking the ratio of moles to volume (in liters):

$$\text{Molarity} = \frac{\text{moles of solute}}{\text{liters of solution}}$$

Solution: The planned solution would have the following molar concentrations:

$$[\mathrm{Pb^{2+}}] = \frac{0.075\ \mathrm{mol}}{0.500\ \mathrm{L}} = 0.15\ M \qquad [\mathrm{Cl^-}] = \frac{0.0075\ \mathrm{mol}}{0.500\ \mathrm{L}} = 0.015\ M$$

It is usually difficult to prevent the extra salt from precipitating out of a supersaturated solution. (Sodium acetate is a notable exception. Supersaturated solutions of this salt are easily made.)

We use these values to compute the ion product for $PbCl_2$ in the solution:

$$Q = [\mathrm{Pb^{2+}}][\mathrm{Cl^-}]^2 = (0.15)(0.015)^2 = 3.4 \times 10^{-5}$$

This value of Q is larger than the K_{sp} of $PbCl_2$, 1.7×10^{-5}, which means that a precipitate of $PbCl_2$ will form if we attempt to prepare this solution.

Is the Answer Reasonable? We can double-check that the molarities of the ions in the planned solution are correct. Then we check the calculation of Q. All seems to be in order, so we have confidence that our answer is correct.

Practice Exercises

18.10 | Calculate the ion product for the solution in which the Ca^{2+} concentration is $0.0025\ M$ and the SO_4^{2-} concentration is $0.030\ M$. Will a precipitate of $CaSO_4$ form in this solution? (*Hint*: What is the form of the ion product for $CaSO_4$?)

18.11 | Calculate the ion product for a solution containing $3.4 \times 10^{-4}\ M$ CrO_4^{2-} and $4.8 \times 10^{-5}\ M$ Ag^+. Will a precipitate form?

Example 18.7
Predicting whether a Precipitate Will Form

What possible precipitate might form by mixing 50.0 mL of $1.0 \times 10^{-4}\ M$ NaCl with 50.0 mL of $1.0 \times 10^{-6}\ M$ $AgNO_3$? Will it form? (Assume the volumes are additive.)

Analysis: In this problem we are being asked, in effect, whether a metathesis reaction will occur between NaCl and $AgNO_3$. We should be able to use the solubility rules in Chapter 5 to predict whether this *might* occur. If the solubility rules suggest a precipitate, we can then calculate the ion product for the compound using the concentrations of the ions in the final solution. If this ion product exceeds K_{sp} for the salt, then a precipitate is expected.

To calculate Q correctly requires that we use the concentrations of the ions *after the solutions have been mixed*. Therefore, before computing the ion product, we must first take into account that mixing the solutions dilutes each of the solutes. Dilution problems were covered in Chapter 5.

To obtain the solution to this problem we must bring together tools from two different chapters.

Assembling the Tools: Our first tool is the solubility rules (page 176), which helps us determine whether each product is soluble or insoluble. Then, we need to use the dilution equation from Chapter 5, Equation 5.6 (page 189), to find the concentrations of the ions for the ion product. Finally, we will use the ion product and compare Q to K_{sp} to determine if a precipitate forms.

■ **Solution:** Let's begin by writing the equation for the potential metathesis reaction between NaCl and $AgNO_3$. The solubility rules (page 176) help us determine whether each product is soluble or insoluble.

$$\text{NaCl}(aq) + \text{AgNO}_3(aq) \longrightarrow \text{AgCl}(s) + \text{NaNO}_3(aq)$$

The solubility rules indicate that we expect a precipitate of AgCl. But are the concentrations of Ag^+ and Cl^- actually high enough?

In the original solutions, the $1.0 \times 10^{-6}\ M$ $AgNO_3$ contains $1.0 \times 10^{-6}\ M$ Ag^+ and the $1.0 \times 10^{-4}\ M$ NaCl contains $1.0 \times 10^{-4}\ M$ Cl^-. What are the concentrations of these ions after dilution? To determine these, we use Equation 5.6, which applies to all dilution problems involving molarity:

$$V_{\text{dil}} \cdot M_{\text{dil}} = V_{\text{conc}} \cdot M_{\text{conc}}$$

Solving for M_{dil} gives

$$M_{\text{dil}} = \frac{M_{\text{conc}} V_{\text{conc}}}{V_{\text{dil}}}$$

The initial volumes of the more concentrated solutions are 50.0 mL, and when the two solutions are combined, the final total volume is 100.0 mL. Therefore,

$$[\text{Ag}^+]_{final} = \frac{(50.0\ \text{mL})(1.0 \times 10^{-6}\ M)}{100.0\ \text{mL}} = 5.0 \times 10^{-7}\ M$$

$$[\text{Cl}^-]_{final} = \frac{(50.0\ \text{mL})(1.0 \times 10^{-4}\ M)}{100.0\ \text{mL}} = 5.0 \times 10^{-5}\ M$$

Now we use these to calculate Q for AgCl, which we can obtain from the dissociation reaction of the salt:

$$\text{AgCl}(s) \rightleftharpoons \text{Ag}^+(aq) + \text{Cl}^-(aq)$$

$$Q = [\text{Ag}^+][\text{Cl}^-]$$

Substituting the concentrations computed above gives

$$Q = (5.0 \times 10^{-7})(5.0 \times 10^{-5}) = 2.5 \times 10^{-11}$$

In Table 18.1, the K_{sp} for AgCl is given as 1.8×10^{10}. Notice that Q is *smaller* than K_{sp}, which means that the final solution is unsaturated in AgCl and a precipitate will *not* form.

■ **Is the Answer Reasonable?** There are several things we should check here. They include writing the equation for the metathesis reaction, calculating the concentrations of the ions after dilution (we've doubled the volume, so the concentrations are halved), and setting up the correct ion product. All appear to be correct, so the answer should be okay.

Practice Exercises

18.12 | What precipitate might be expected if we mix 100.0 mL of $1.0 \times 10^{-3}\ M$ $Pb(NO_3)_2$ and 100.0 mL of $2.0 \times 10^{-3}\ M$ $MgSO_4$? Will some precipitate form? Assume that the volumes are additive. (*Hint*: What tools will you need to solve the problem?)

18.13 | What precipitate might be expected if we mix 50.0 mL of 0.10 M $Pb(NO_3)_2$ and 20.0 mL of 0.040 M NaCl? Will some precipitate form? Assume that the volumes are additive.

Analyzing and Solving Multi-Concept Problems

A saturated solution of $PbCl_2$ has a freezing point of $-0.089\ °C$. What is the K_{sp} of $PbCl_2$ as determined by the freezing point depression value? Assume that lead(II) chloride dissociates completely and that the density of the solution is $1.00\ g\ mL^{-1}$.

Analysis In this question we are asked to find the K_{sp} for the $PbCl_2$. In order to do this, we need to find the concentration of the $PbCl_2$. We are given the freezing point depression for the solution, so we can use this to determine the concentration of the solute.

PART 1

Assembling the Tools The first tool we will need is the freezing point depression equation,

$$\Delta T_f = K_f m$$

Solution Let us rearrange the equation to find the molality of the solution

$$\begin{aligned}\Delta T_f &= K_f m \\ m &= \frac{\Delta T_f}{K_f}\end{aligned}$$

We have the ΔT_f, which equals 0.089 °C, and from Table 13.3 (page 609), $K_f = 1.86\ °C\ m^{-1}$. Substituting these values into the equation gives us

$$\begin{aligned}m &= \frac{0.089\ \cancel{°C}}{1.86\ \cancel{°C}\ m^{-1}} \\ m &= 0.048\ m\end{aligned}$$

Now this gives us the molality of all of the ions in the solution, but we need the molarity, so we also need to convert between molality (moles of solute per kilogram of solvent) and molarity (moles of solute per liter of solution). We are given the density of the solution as $1.00\ g\ mL^{-1}$.

$$\begin{aligned}M &= \frac{0.048\ \text{mol solute}}{1\ \cancel{\text{kg of water}}} \times \frac{1\ \cancel{\text{kg water}}}{1000\ \cancel{\text{g water}}} \times \frac{1.00\ \cancel{\text{g water}}}{1.00\ \cancel{\text{mL solution}}} \times \frac{1000\ \cancel{\text{mL solution}}}{1\ \text{L solution}} \\ M &= 0.048\ \text{mol L}^{-1}\end{aligned}$$

PART 2

Assembling the Tools Now that we have the molarity of the ions in the solution, we need to determine the K_{sp}. We now use the molarity of the ions, the chemical equation, and its solubility product expression to solve the problem.

Solution Before we start substituting numbers into the solubility product expression, we have to think about what happened to bring the ions into solution. The $PbCl_2$ dissolved, the ions dissociated, and for each $PbCl_2$ formula unit that dissolved, one Pb^{2+} and two Cl^- went into solution. So if x moles of $PbCl_2$ dissolved, then x mole of Pb^{2+} and $2x$ moles of Cl^- are in solution. The volume of the solution is the same for lead and chloride, so we can add the molarities instead of the moles. To calculate the actual concentration of each ion in solution we have

$$\begin{aligned}0.048\ M\ \text{ions} &= x\ M\ Pb^{2+} + 2x\ M\ Cl^- \\ 0.048\ M\ \text{ions} &= 3x\ M \\ x &= 0.016\ M\end{aligned}$$

$$[Pb^{2+}] = 0.016\ M \quad \text{and} \quad [Cl^-] = 0.032\ M$$

Now we can substitute these values into the expression for K_{sp}.

$$PbCl_2(s) \rightleftharpoons Pb^{2+} + 2Cl^-$$
$$K_{sp} = [Pb^{2+}][Cl^-]^2$$
$$K_{sp} = [0.016][0.032]^2$$
$$K_{sp} = 1.6 \times 10^{-5}$$

■ **Are the Answers Reasonable?** The freezing point depression is relatively small, so we do not expect to have very much solute dissolved, and from our calculations, this is correct. Next, we have calculated a K_{sp} value that is very similar to the value in Table 18.1, so this is also an indication that our calculation is correct. Finally, we realized that the total ion concentration comes from the dissociation of the ions, so the concentration of each ion is a fraction of the total ion concentration.

■ The low solubility of the salt indicates that our assumption about completely dissociated ions is reasonable.

18.2 | Equilibria in Solutions of Metal Oxides and Sulfides

Aqueous equilibria involving insoluble oxides and sulfides are more complex than those we've considered so far because of reactions of the anions with the solvent, water.

When a metal oxide dissolves in water, it does so by reacting with water instead of by a simple dissociation of ions that remain otherwise unchanged. Sodium oxide, for example, consists of Na^+ and O^{2-} ions, and it readily dissolves in water. The solution, however, does not contain the oxide ion, O^{2-}. Instead, the hydroxide ion forms. The equation for the reaction is

$$Na_2O(s) + H_2O \longrightarrow 2NaOH(aq)$$

This actually involves the reaction of oxide ions with water as the crystals of Na_2O break up:

$$O^{2-}(s) + H_2O \longrightarrow 2OH^-(aq)$$

The oxide ion is simply too powerful a base to exist in water at any concentration worthy of experimental note. We can understand why from the extraordinarily high (estimated) value of K_b for O^{2-}, 1×10^{22}. Thus, there is no way to supply *oxide ions* to an aqueous solution in order to form an insoluble metal oxide directly. Oxide ions react with water, instead, to generate the hydroxide ion. When an insoluble metal *oxide* instead of an insoluble metal *hydroxide* does precipitate from a solution, it forms because the specific metal ion is able to react with OH^-, extract O^{2-}, and leave H^+ (or H_2O) in the solution. The silver ion, for example, precipitates as brown silver oxide, Ag_2O, when OH^- is added to aqueous silver salts (Figure 18.3):

$$2Ag^+(aq) + 2OH^-(aq) \longrightarrow Ag_2O(s) + H_2O$$

The reverse of this reaction, written as an equilibrium, corresponds to the solubility equilibrium for Ag_2O:

$$Ag_2O(s) + H_2O \rightleftharpoons 2Ag^+(aq) + 2OH^-(aq)$$

Figure 18.3 | **Silver oxide.** A brown, mud-like precipitate of silver oxide forms as a sodium hydroxide solution is added to a solution of silver nitrate. *(Michael Watson)*

Solubility Equilibria for Metal Sulfides and Oxides

When we shift from oxygen to sulfur in Group 6A and consider metal sulfides, we find many similarities to oxides. One is that the sulfide ion, S^{2-}, like the oxide ion, O^{2-}, is such a strong Brønsted–Lowry base that it does not exist in any ordinary aqueous solution.

The sulfide ion has not been detected in an aqueous solution, even in the presence of 8 *M* NaOH, where one might think that the reaction

$$OH^- + HS^- \longrightarrow H_2O + S^{2-}$$

could generate some detectable S^{2-}. An 8 *M* NaOH solution is at a concentration well outside the bounds of the "ordinary." Thus, Na_2S, like Na_2O, dissolves in water *by reacting with it,* not by releasing an otherwise unchanged divalent anion, S^{2-}:

$$Na_2S(s) + H_2O \longrightarrow 2Na^+(aq) + HS^-(aq) + OH^-(aq)$$

As with Na_2O, water reacts with the sulfide ion as the crystals break apart and the ions enter the solution:

$$S^{2-}(s) + H_2O \longrightarrow HS^-(aq) + OH^-(aq)$$

■ In the laboratory, the qualitative analysis of metal ions uses the precipitation of metal sulfides to separate some metal ions from others.

The sulfides of most metals have quite low solubilities in water. Simply bubbling hydrogen sulfide gas into an aqueous solution of any one of a number of metal ions—Cu^{2+}, Pb^{2+}, and Ni^{2+}, for example—causes their sulfides to precipitate. Many of these have distinctive colors (Figure 18.4) that can be used to help identify which metal ion is in solution.

To write the solubility equilibrium for an insoluble metal sulfide, we have to take into account the reaction of the sulfide ion with water. For example, for CuS the equilibrium is best written as

$$CuS(s) + H_2O \rightleftharpoons Cu^{2+}(aq) + HS^-(aq) + OH^-(aq) \tag{18.2}$$

This equation yields the ion product $[Cu^{2+}][HS^-][OH^-]$, and the solubility product constant for CuS is expressed by the equation,

$$K_{sp} = [Cu^{2+}][HS^-][OH^-]$$

Values of K_{sp} of this form for a number of metal sulfides are listed in the last column in Table 18.2. Notice particularly how much the K_{sp} values vary—from 2×10^{-53} to 3×10^{-11}, a spread of a factor of 10^{42}.

Acid-Insoluble Sulfides

Many metal sulfides are able to react with acid and thereby dissolve. An example is zinc sulfide:

$$ZnS(s) + 2H^+(aq) \longrightarrow Zn^{2+}(aq) + H_2S$$

However, some metal sulfides, referred to as the *acid-insoluble sulfides,* have K_{sp} values so low that they do not dissolve in acid. The cations in this group can be precipitated from the other cations simply by bubbling hydrogen sulfide into a sufficiently acidic solution that contains several metal ions.

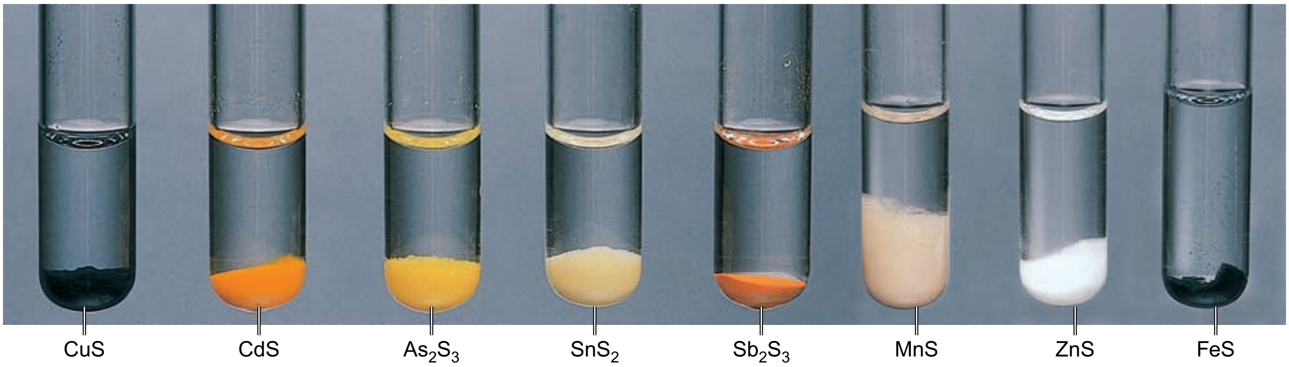

Figure 18.4 | **The colors of some metal sulfides.** *(OPC, Inc.)*

Table 18.2 **Metal Ions Separable by Selective Precipitation of Sulfides**[a]

Metal Ion	Sulfide	K_{spa}	K_{sp}
Acid-Insoluble Sulfides			
Hg^{2+}	HgS (black form)	2×10^{-32}	2×10^{-53}
Ag^{+}	Ag_2S	6×10^{-30}	6×10^{-51}
Cu^{2+}	CuS	6×10^{-16}	6×10^{-37}
Cd^{2+}	CdS	8×10^{-7}	8×10^{-28}
Pb^{2+}	PbS	3×10^{-7}	3×10^{-28}
Sn^{2+}	SnS	1×10^{-5}	1×10^{-26}
Base-Insoluble Sulfides (Acid-Soluble Sulfides)			
Zn^{2+}	α–ZnS	2×10^{-4}	2×10^{-25}
	β–ZnS	3×10^{-2}	3×10^{-23}
Co^{2+}	CoS	5×10^{-1}	5×10^{-22}
Ni^{2+}	NiS	4×10^{1}	4×10^{-20}
Fe^{2+}	FeS	6×10^{2}	6×10^{-19}
Mn^{2+}	MnS (pink form)	3×10^{10}	3×10^{-11}
	MnS (green form)	3×10^{7}	3×10^{-14}

[a] Data are for 25 °C. See R. J. Meyers, *J. Chem. Ed.*, vol. 63, 1986, p. 687.

When the solution is acidic, we have to treat the solubility equilibria differently. In acid, HS^- and OH^- would be neutralized, leaving their conjugate acids, H_2S and H_2O. Under these conditions, the equation for the solubility equilibrium becomes

$$\mathrm{CuS}(s) + 2\mathrm{H}^+(aq) \rightleftharpoons \mathrm{Cu}^{2+}(aq) + \mathrm{H_2S}(aq)$$

This changes the mass action expression for the solubility product equilibrium, which we will now call the **acid solubility product, K_{spa}**. The *a* in the subscript indicates that the medium is acidic.

$$K_{spa} = \frac{[\mathrm{Cu}^{2+}][\mathrm{H_2S}]}{[\mathrm{H}^+]^2}$$

TOOLS

Acid solubility product constant, K_{spa}

Table 18.2 also lists K_{spa} values for the metal sulfides. Notice that all K_{spa} values are about 10^{21} larger than the K_{sp} values. Metal sulfides are clearly vastly more soluble in dilute acid than in water. Yet several—the acid-insoluble sulfides—are so insoluble that even the most soluble of them, SnS, barely dissolves, even in moderately concentrated acid. So, there are two families of sulfides, the *acid-insoluble sulfides* and the acid-soluble ones, otherwise known as the *base-insoluble sulfides*. As we discuss in Section 18.3, the differing solubilities of their sulfides in acid provide a means of separating the two classes of metal ions from each other.

18.3 | Selective Precipitation

Selective precipitation means causing one metal ion to precipitate while holding another in solution. Often this is possible because of large differences in the solubilities of salts that we would generally consider to be insoluble. For example, the K_{sp} values for AgCl and $PbCl_2$ are 1.8×10^{-10} and 1.7×10^{-5}, respectively, which gives them molar solubilities in water of 1.3×10^{-5} *M* for AgCl and 1.6×10^{-2} *M* for $PbCl_2$. In terms of molar solubilities, lead(II) chloride is approximately 1200 times more soluble in water than AgCl. If we had a solution containing both 0.10 *M* Pb^{2+} and 0.10 *M* Ag^+ and began adding Cl^-, AgCl would precipitate first (Figure 18.5). In fact, we can calculate that before any $PbCl_2$

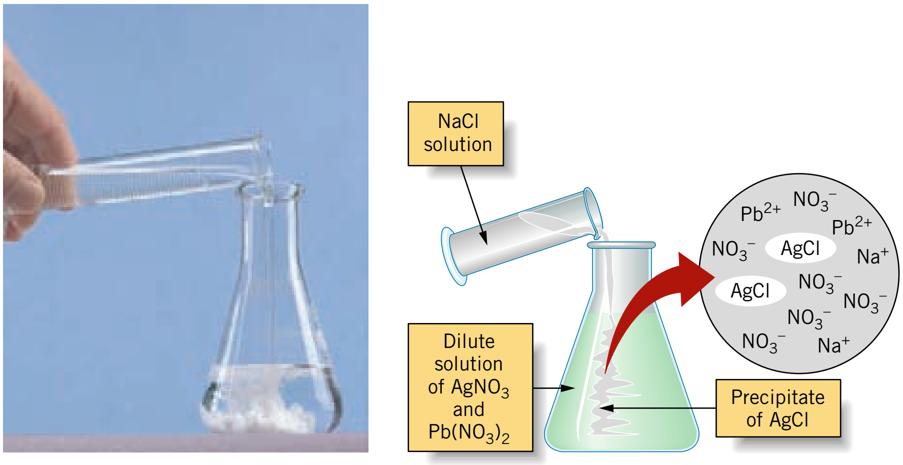

Figure 18.5 | **Selective precipitation.** When dilute sodium chloride is added to a solution containing both Ag^+ ions and Pb^{2+} ions (both dissolved as their nitrate salts), the less soluble AgCl precipitates before the more soluble $PbCl_2$. Precipitation of the AgCl is nearly complete before any $PbCl_2$ begins to form. *(Andy Washnik)*

starts to precipitate, the concentration of Ag^+ will have been reduced to 1.6×10^{-8} *M*. Thus, nearly all of the silver is removed from the solution without precipitating any of the lead, and the ions are effectively separated. All we need to do is find a way of adjusting the concentration of the Cl^- to achieve the separation.

Example 18.8
Selective Precipitation of Silver Halides

If a solution contains 0.10 *M* Cl^- and 0.10 *M* I^-, then what concentration of $AgNO_3$ will allow the separation of these halides by selective precipitation?

Analysis: We are being asked to find the concentration of Ag^+ ions that will remove one of the ions from the solution while leaving the other behind. We will have to decide which solid will precipitate first, and then determine the concentration of the silver ions that will precipitate the first solid and leave the second solid dissolved in the solution.

Assembling the Tools: From Table 18.1, we can find the ion product constants

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \qquad K_{sp} = 1.8 \times 10^{-10}$$
$$AgI(s) \rightleftharpoons Ag^+(aq) + I^-(aq) \qquad K_{sp} = 8.5 \times 10^{-17}$$

Silver iodide is much less soluble than silver chloride, so silver iodide will precipitate first, and the silver iodide solid can be filtered off to leave the chloride ions in solution.

Next, we have to determine the concentration of the silver ions that will precipitate the iodide. To do this, we can imagine that we start with no silver in solution, and that we slowly add the silver ions. As we increase the concentration of the silver, the iodide precipitates; this is the lowest concentration of silver that needs to be added. Then, we add more silver, and more iodide precipitates, until at a certain concentration, the solution becomes saturated in AgCl. This is the maximum concentration of Ag^+ that we can have without causing AgCl to precipitate. This is what we need to calculate.

Solution: We can start by determining what concentration of Ag^+ will precipitate AgCl. We know that the concentration of Cl^- is 0.10 *M*, so we can use the solubility product expression to solve for the concentration of Ag^+ required to produce saturation:

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq)$$
$$K_{sp} = [Ag^+][Cl^-]$$
$$1.8 \times 10^{-10} = [Ag^+](0.10\ M)$$
$$1.8 \times 10^{-9}\ M = [Ag^+]$$

As long as the concentration of the silver ion is kept at or below $1.8 \times 10^{-9}\ M$, then the chloride ion will *not* precipitate. Now the question is, will the I^- concentration be reduced enough to consider the ions to be effectively separated?

Let's use the concentration of silver ions to calculate how much iodide will be in solution:

$$\begin{aligned} AgI(s) &\rightleftharpoons Ag^+(aq) + I^-(aq) \\ K_{sp} &= [Ag^+][I^-] \\ 8.5 \times 10^{-17} &= (1.8 \times 10^{-9}\ M)[I^-] \\ 4.7 \times 10^{-8}\ M &= [I^-] \end{aligned}$$

The iodide was $0.10\ M$ before the addition of the silver ions, and now it is $4.7 \times 10^{-8}\ M$. We can consider the iodide completely precipitated. So the maximum concentration of silver ion needed to achieve effective separation is $1.8 \times 10^{-9}\ M$.

Is the Answer Reasonable? From our work we showed that the silver iodide precipitated well before the silver chloride. Considering the differences in the K_{sp} values, this is to be expected. We can go back and check the math, and make sure that our reasoning was correct.

Practice Exercises

18.14 | If a solution contains calcium ions ($0.25\ M$) and barium ions ($0.05\ M$), what concentration of SO_4^{2-} would be required to selectively precipitate the barium ions from solution? (*Hint*: First find the concentration of sulfate ions that will cause the calcium ions to precipitate.)

18.15 | A solution contains $0.20\ M$ $CaCl_2$ and $0.10\ M$ $MgCl_2$. What concentration of hydroxide ions would be required to separate the magnesium as $Mg(OH)_2$ without precipitating the calcium as $Ca(OH)_2$?

Metal Sulfides

The large differences in K_{spa} values between the acid-insoluble and the base-insoluble metal sulfides make it possible to separate the corresponding cations from each other by adjusting the pH of the solution. The sulfides of the acid-insoluble cations are selectively precipitated by hydrogen sulfide from a solution by adjusting the pH so that the other cations remain in solution. A solution saturated in H_2S is used, for which the molarity of H_2S is $0.1\ M$.

Example 18.9 shows how we can calculate the pH needed to selectively precipitate two metal cations as their sulfides. We will use Cu^{2+} and Ni^{2+} ions to represent a cation from each class.

Example 18.9

Selective Precipitation of the Sulfides of Acid-Insoluble Cations from Base-Insoluble Cations

Over what range of hydrogen ion concentrations (and pH) is it possible to separate Cu^{2+} from Ni^{2+} when both metal ions are present in a solution at a concentration of $0.010\ M$ and the solution is made saturated in H_2S (where $[H_2S] = 0.1\ M$)?

Analysis: Both the concentration of the H_2S and the Cu^{2+} and Ni^{2+} ions are known, so we are only changing the concentration of the hydrogen ion, and we are being asked for a range of hydrogen ion concentrations. The low end of the hydrogen ion concentration will be the more basic solution, and the high end will be the more acidic solution. Sulfides become more soluble as the hydrogen ion concentration increases.

The problem reduces to two questions. The first question is: What is the most basic solution that will keep the more soluble sulfide in solution? The answer to this will be the *lower limit* on $[H^+]$. At any lower H^+ concentration, this compound will precipitate, so we want an H^+ concentration equal to or greater than this value. The second question is: What hydrogen ion concentration would be needed to keep the less soluble sulfide *in solution*? (The answer to this question will give us the *upper limit* on $[H^+]$; we would really want a lower H^+ concentration, so the less soluble sulfide *will* precipitate.) Once we know these limits, we know that any hydrogen ion concentration in between them will permit the less soluble sulfide to precipitate but retain the more soluble sulfide in solution.

■ **Assembling the Tools:** We need the appropriate equilibrium expressions and the K_{spa} values from Table 18.2, from which we can write the equilibrium laws needed to work the problem:

$$CuS(s) + 2H^+(aq) \rightleftharpoons Cu^{2+}(aq) + H_2S(aq) \qquad K_{spa} = \frac{[Cu^{2+}][H_2S]}{[H^+]^2} = 6 \times 10^{-16}$$

$$NiS(s) + 2H^+(aq) \rightleftharpoons Ni^{2+}(aq) + H_2S(aq) \qquad K_{spa} = \frac{[Ni^{2+}][H_2S]}{[H^+]^2} = 4 \times 10^{1}$$

NiS is much more soluble in an acidic solution than CuS. As the concentration of H^+ increases, the more soluble the NiS will be. (Actually, both will become more soluble, but NiS is much more soluble than CuS.) Therefore, we need an H^+ concentration that will be large enough to prevent NiS from precipitating, but small enough so that CuS does precipitate. We will use the equilibrium constant expressions to calculate the H^+ concentrations for the limits of the solubility of CuS and NiS.

■ **Solution:** We will obtain the lower limit first, by calculating the $[H^+]$ required based on a concentration of Ni^{2+} equal to 0.010 M and an H_2S concentration of 0.1 M. If we keep the value of $[H^+]$ *equal to or larger* than this value, then NiS will be prevented from precipitating. First, we substitute values into the K_{spa} expression:

$$K_{spa} = \frac{[Ni^{2+}][H_2S]}{[H^+]^2} = \frac{(0.010)(0.1)}{[H^+]^2} = 4 \times 10^{1}$$

Now we solve for $[H^+]$:

$$[H^+]^2 = \frac{(0.010)(0.1)}{4 \times 10^{1}}$$

$$[H^+] = 5 \times 10^{-3}\ M$$

At any $[H^+]$ lower than this, the $[H^+]$ will not be great enough to keep the NiS in solution. This is a pH of 2.3.

Next, we will find the upper limit. If CuS *does not precipitate*, the Cu^{2+} concentration will be the given value, 0.010 M, so we substitute this along with the H_2S concentration (0.1 M) into the expression for K_{spa} of Cu^{2+}:

$$K_{spa} = \frac{[Cu^{2+}][H_2S]}{[H^+]^2} = \frac{(0.010)(0.1)}{[H^+]^2} = 6 \times 10^{-16}$$

Now we solve for $[H^+]$:

$$[H^+]^2 = \frac{(0.010)(0.1)}{6 \times 10^{-16}} = 2 \times 10^{12}$$

$$[H^+] = 1 \times 10^{6}\ M$$

If we could make $[H^+] = 1 \times 10^6\ M$, we could prevent CuS from forming. However, it isn't possible to have 10^6 or a *million* moles of H^+ per liter! What the calculated $[H^+]$ tells us, therefore, is that *no matter how acidic the solution is, we cannot prevent* CuS *from precipitating when we saturate the solution with* H_2S. (You can now see why CuS is classed as an "acid-insoluble sulfide.")

Now, we have our limits: the lower limit for the concentration of H^+ is $5 \times 10^{-3}\ M$ and there is no actual higher limit, since the theoretical higher limit is beyond any possible physical means.

If we maintain the pH of the solution of 0.010 M Cu^{2+} and 0.010 M Ni^{2+} at 2.3 or lower (more acidic), as we make the solution saturated in H_2S, then virtually all of the Cu^{2+} will precipitate as CuS, but all of the Ni^{2+} will remain in solution.

■ **Is the Answer Reasonable?** The K_{spa} values certainly tell us that CuS is quite insoluble in acid and that NiS is a lot more soluble, so from that standpoint the results seem reasonable. There's not much more we can do to check the answer, other than to review the entire set of calculations.

Practice Exercises

18.16 | Suppose a solution contains 0.0050 M Co^{2+} and is saturated with H_2S (with $[H_2S] = 0.1\ M$). Would CoS precipitate if the solution has a pH of 3.5? (*Hint*: What relationship do we use to determine whether a precipitate is going to form in a solution?)

18.17 | Consider a solution containing Hg^{2+} and Fe^{2+}, both at molarities of 0.010 M. It is to be saturated with H_2S. Calculate the highest pH that this solution could have that would keep Fe^{2+} in solution while causing Hg^{2+} to precipitate as HgS.

In actual lab work, separation of the acid-insoluble sulfides from the base-insoluble ones is performed with $[H^+] \approx 0.3\ M$, which corresponds to a pH of about 0.5. This ensures that the base-insoluble sulfides will not precipitate. The calculation in Example 18.9 also demonstrated why NiS can be classified as a "base-insoluble sulfide." If the solution is *basic* when it is made saturated in H_2S, the pH will surely be larger than 2.3 and NiS will precipitate.

Metal Carbonates

The principles of selective precipitation by the control of pH apply to any system where the anion is that of a weak acid. The metal carbonates can also be selectively precipitated, with many being quite insoluble in water (see Table 18.1). The dissociation of magnesium carbonate in water, for example, involves the following equilibrium and K_{sp} equations:

$$MgCO_3(s) \rightleftharpoons Mg^{2+}(aq) + CO_3^{\ 2-}(aq) \qquad K_{sp} = 6.8 \times 10^{-8}$$

For strontium carbonate, the equations are

$$SrCO_3(s) \rightleftharpoons Sr^{2+}(aq) + CO_3^{\ 2-}(aq) \qquad K_{sp} = 5.6 \times 10^{-10}$$

Would it be possible to separate the magnesium ion from the strontium ion by taking advantage of the difference in K_{sp} of their carbonates?

We can do so if we can control the carbonate ion concentration. Because the carbonate ion is a relatively strong Brønsted–Lowry base, its control is available, indirectly, by adjusting the pH of the solution. This is because the hydrogen ion is one of the species in each of the following equilibria.[3]

$$H_2CO_3(aq) \rightleftharpoons H^+(aq) + HCO_3^{\ -}(aq) \qquad K_{a_1} = 4.3 \times 10^{-7}$$
$$HCO_3^{\ -}(aq) \rightleftharpoons H^+(aq) + CO_3^{\ 2-}(aq) \qquad K_{a_2} = 5.6 \times 10^{-11}$$

---

[3] The situation involving aqueous carbonic acid is complicated by the presence of dissolved CO_2, which we could represent in an equation as $CO_2(aq)$. In fact, this is how most of the dissolved CO_2 exists—namely, as $CO_2(aq)$, not as $H_2CO_3(aq)$. However, we may use $H_2CO_3(aq)$ as a surrogate or stand-in for $CO_2(aq)$, because the latter changes smoothly to the former on demand. The following two successive equilibria involving carbonic acid exist in a solution of aqueous CO_2:

$$CO_2(aq) + H_2O \rightleftharpoons H_2CO_3(aq) \rightleftharpoons H^+(aq) + HCO_3^{\ -}(aq)$$

The value of K_{a_1} cited here for $H_2CO_3(aq)$ is really the product of the equilibrium constants of these two equilibria.

You can see that if we increase the hydrogen ion concentration, both equilibria will shift to the left, in accordance with Le Châtelier's principle, and this will reduce the concentration of the carbonate ion. The value of $[CO_3^{2-}]$ thus decreases with decreasing pH. On the other hand, if we decrease the hydrogen ion concentration, making the solution more basic, we will cause the two equilibria to shift to the right. The concentration of the carbonate ion thus increases with increasing pH.

For the calculations ahead, it will be useful to combine the two hydrogen carbonate equilibria into one overall equation that relates the molar concentrations of carbonic acid, carbonate ion, and hydrogen ion. So, we first add the two:

$$\begin{array}{rcl} H_2CO_3(aq) & \rightleftharpoons & H^+(aq) + HCO_3^-(aq) \\ HCO_3^-(aq) & \rightleftharpoons & H^+(aq) + CO_3^{2-}(aq) \\ \hline H_2CO_3(aq) & \rightleftharpoons & 2H^+(aq) + CO_3^{2-}(aq) \end{array} \tag{18.3}$$

Recall from Chapter 15 that when we add two equilibria to get a third, the equilibrium constant of the latter is the product of those of the two equilibria that are combined. Thus, for Equation 18.3, the equilibrium constant, which we'll symbolize as K_a, is obtained as follows:

Combined K_a expression for a diprotic acid

$$K_a = K_{a_1} \times K_{a_2} = \frac{[H^+]^2[CO_3^{2-}]}{[H_2CO_3]} \tag{18.4}$$

$$= (4.3 \times 10^{-7}) \times (5.6 \times 10^{-11})$$

$$= 2.4 \times 10^{-17}$$

■ We can safely use Equation 18.4 *only* when two of the three concentrations are known.

With this K_a value we may now study how to find the pH range within which Mg^{2+} and Sr^{2+} can be separated by taking advantage of their difference in K_{sp} values. To perform such a separation we would saturate a solution with CO_2, which provides H_2CO_3 through the rapidly established equilibrium,

$$CO_2(aq) + H_2O \rightleftharpoons H_2CO_3(aq)$$

Thus, a solution that contains 0.030 M CO_2 has an effective H_2CO_3 concentration of 0.030 M.

Example 18.10

Separation of Metal Ions by the Selective Precipitation of Their Carbonates

A solution contains magnesium nitrate and strontium nitrate, each at a concentration of 0.10 M. Carbon dioxide is to be bubbled in to make the solution saturated in $CO_2(aq)$—approximately 0.030 M. What pH range would make it possible for the carbonate of one cation to precipitate but not that of the other?

■ **Analysis:** There are really two parts to this. First, what is the range in values of $[CO_3^{2-}]$ that allow one carbonate to precipitate but not the other? Second, given this range, what are the values of the solution's pH that produce this range in $[CO_3^{2-}]$ values?

To answer the first question, we will use the K_{sp} values of the two carbonate salts and their molar concentrations to find the CO_3^{2-} concentrations in their saturated solutions. To keep the more soluble carbonate from precipitating, the CO_3^{2-} concentration must be at or below that required for saturation. For the less soluble of the two, we must have a CO_3^{2-} concentration larger than in a saturated solution so that it will precipitate.

To answer the second question, we will use the combined K_a expression for H_2CO_3 to find the $[H^+]$ that gives the necessary CO_3^{2-} concentrations obtained in answering the first question. Having these $[H^+]$, it is then a simple matter to convert them to pH values.

■ **Assembling the Tools:** The tools we need to solve the problem are the K_{sp} values and equilibria for $MgCO_3$ and $SrCO_3$:

$$K_{sp} = [Mg^{2+}][CO_3^{2-}] = 6.8 \times 10^{-8}$$
$$K_{sp} = [Sr^{2+}][CO_3^{2-}] = 5.6 \times 10^{-10}$$

We also need the combined K_a expression for carbonic acid:

$$K_a = \frac{[H^+]^2[CO_3^{2-}]}{[H_2CO_3]} = 2.4 \times 10^{-17}$$

■ **Solution:** Let's find the $[CO_3^{2-}]$ values required to give saturated solutions of these two salts.

For magnesium carbonate:

$$[CO_3^{2-}] = \frac{K_{sp}}{[Mg^{2+}]} = \frac{6.8 \times 10^{-8}}{0.10} = 6.8 \times 10^{-7}\ M$$

For strontium carbonate:

$$[CO_3^{2-}] = \frac{K_{sp}}{[Sr^{2+}]} = \frac{5.6 \times 10^{-10}}{0.10} = 5.6 \times 10^{-9}\ M$$

On the basis of the K_{sp} values, we see that $MgCO_3$ is the more soluble of the two. For separation, we have to keep the $[CO_3^{2-}]$ larger than 5.6×10^{-9} *M* and less than or equal to 6.8×10^{-7} *M* to keep the $MgCO_3$ in solution and to precipitate the $SrCO_3$.

$[CO_3^{2-}] > 5.6 \times 10^{-9}\ M$ (to precipitate $SrCO_3$)
$[CO_3^{2-}] \leq 6.8 \times 10^{-7}\ M$ (to prevent $MgCO_3$ from precipitating)

The second phase of our calculation now asks what values of $[H^+]$ correspond to the calculated limits on $[CO_3^{2-}]$. For this we will use the K_a expression given by Equation 18.3. First, we solve for the square of $[H^+]$, using the molarity of the dissolved CO_2, 0.030 *M*, as the value of $[H_2CO_3]$. This gives us

$$[H^+]^2 = K_a \times \frac{[H_2CO_3]}{[CO_3^{2-}]}$$
$$[H^+]^2 = 2.4 \times 10^{-17} \times \frac{0.030}{[CO_3^{2-}]}$$

We will use this equation for each of the two boundary values of $[CO_3^{2-}]$ to calculate the corresponding two values of $[H^+]^2$. Once we have them, we can readily determine $[H^+]$ and pH.

For magnesium carbonate: To *prevent* the precipitation of $MgCO_3$, $[CO_3^{2-}]$ must be no higher than 3.5×10^{-7} *M*, so $[H^+]^2$ must not be less than

$$[H^+]^2 = 2.4 \times 10^{-17} \times \frac{0.030}{6.8 \times 10^{-17}} = 1.1 \times 10^{-12}$$
$$[H^+] = 1.0 \times 10^{-6}\ M$$

This corresponds to a pH of 6.00. At a higher (more basic) pH, magnesium carbonate precipitates. Thus, pH $\leq$ 6.00 prevents the precipitation of $MgCO_3$.

For strontium carbonate: To have a saturated solution of $SrCO_3$ with $[Sr^{2+}] = 0.10\ M$, the value of $[CO_3^{2-}]$ would be $5.6 \times 10^{-9}\ M$, as we calculated previously. This corresponds to a value of $[H^+]^2$ found as follows:

$$[H^+]^2 = 2.4 \times 10^{-17} \times \frac{0.030}{5.6 \times 10^{-9}} = 1.3 \times 10^{-10}$$

$$[H^+] = 1.1 \times 10^{-5}\ M$$

$$pH = 4.95$$

To cause $SrCO_3$ to precipitate, the $[CO_3^{2-}]$ would have to be higher than $5.6 \times 10^{-9}\ M$, and that would require that $[H^+]$ be *less than* $1.1 \times 10^{-5}\ M$. If $[H^+]$ were less than $1.1 \times 10^{-5}\ M$, the pH would have to be higher than 4.95. Thus, to cause $SrCO_3$ to precipitate from the given solution, pH $>$ 4.95.

In summary, when the pH of the given solution is kept above 4.95 and less than or equal to 6.00, Sr^{2+} will precipitate as $SrCO_3$, but Mg^{2+} will remain dissolved.

■ **Is the Answer Reasonable?** The only way to be sure of the answer is to go back over the reasoning and the calculations. However, there is a sign that the answer is probably correct. Notice that the two K_{sp} values are not vastly different—they differ by just a factor of about 40. Therefore, it's not surprising that to achieve separation we would have to keep the pH within a rather narrow range (from 4.95 to 6.00).

Practice Exercises

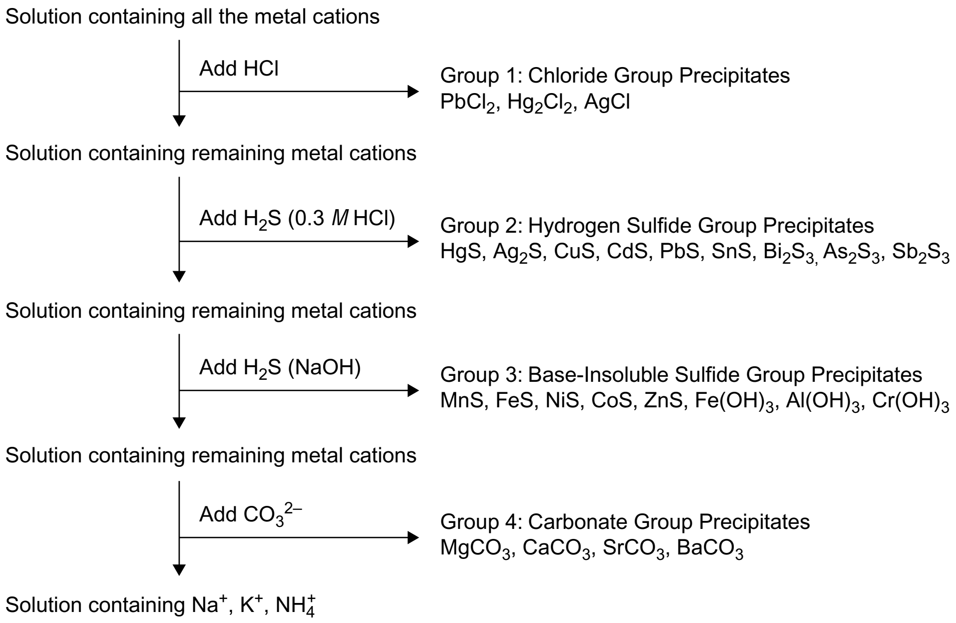
18.18 | The K_{sp} for barium oxalate, BaC_2O_4, is 1.2×10^{-7} and for oxalic acid, $H_2C_2O_4$, $K_{a_1} = 6.0 \times 10^{-2}$ and $K_{a_2} = 6.1 \times 10^{-5}$. If a solution containing 0.10 M $H_2C_2O_4$ and 0.050 M $BaCl_2$ is prepared, what must the minimum H^+ concentration be in the solution to prevent the formation of a BaC_2O_4 precipitate? (*Hint*: Work with a combined K_a expression for $H_2C_2O_4$.)

18.19 | A solution contains calcium nitrate and nickel nitrate, each at a concentration of 0.10 M. Carbon dioxide is to be bubbled in to make its concentration equal 0.030 M. What pH range would make it possible for the carbonate of one cation to precipitate but not that of the other?

Separating Metal Ions: Qualitative Analysis

The method for determining what elements are present in a sample is called *qualitative analysis*. Metal ions can be separated and isolated by selective precipitation with different anions at different pH values. The metal cations have been divided into five groups, depending on the solubilities of their compounds.

The first group is the chloride group, which will precipitate Pb^{2+}, Hg_2^{2+}, and Ag^+. This precipitation reaction is carried out by adding HCl to the solution. To precipitate the next group, the concentration of HCl is brought to 0.3 M and H_2S is added. All of the acid-insoluble sulfides will precipitate (Hg^{2+}, Ag^+, Cu^{2+}, Cd^{2+}, Pb^{2+}, and Sn^{2+} from Table 18.2, as well as Bi^{3+}, As^{3+}, and Sb^{3+}). The third group is precipitated by the addition of NaOH, which will make the solution basic. The compounds MnS, FeS, NiS, CoS, and ZnS will precipitate as base-insoluble sulfides along with the hydroxides $Fe(OH)_3$, $Al(OH)_3$, and $Cr(OH)_3$. For the fourth group, CO_3^{2-} is added to the solution and the following carbonates are precipitated: $MgCO_3$, $CaCO_3$, $SrCO_3$, and $BaCO_3$. The final group is the metal cations that are completely soluble—namely, Na^+, K^+, and NH_4^+. This scheme is summarized in Figure 18.6.



Solution containing all the metal cations
Add HCl
Group 1: Chloride Group Precipitates
$PbCl_2$, Hg_2Cl_2, AgCl
Solution containing remaining metal cations
Add H_2S (0.3 *M* HCl)
Group 2: Hydrogen Sulfide Group Precipitates
HgS, Ag_2S, CuS, CdS, PbS, SnS, Bi_2S_3, As_2S_3, Sb_2S_3
Solution containing remaining metal cations
Add H_2S (NaOH)
Group 3: Base-Insoluble Sulfide Group Precipitates
MnS, FeS, NiS, CoS, ZnS, $Fe(OH)_3$, $Al(OH)_3$, $Cr(OH)_3$
Solution containing remaining metal cations
Add CO_3^{2-}
Group 4: Carbonate Group Precipitates
$MgCO_3$, $CaCO_3$, $SrCO_3$, $BaCO_3$
Solution containing Na^+, K^+, NH_4^+

Figure 18.6 | **Outline of the qualitative analysis scheme.**

18.4 | Equilibria Involving Complex Ions

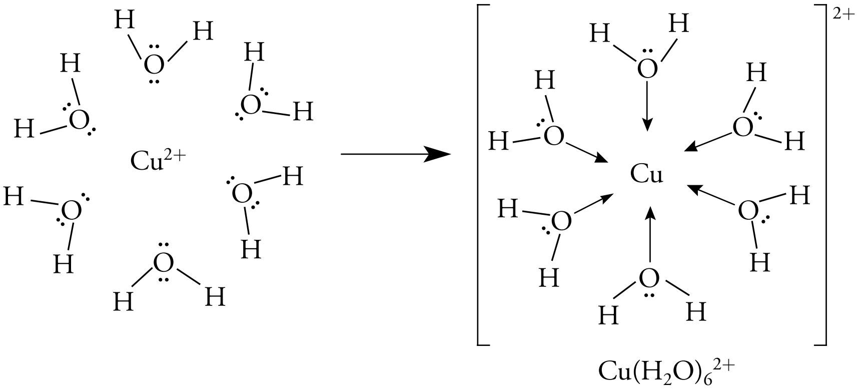
Formation of Complex Ions

In our previous discussions of metal-containing compounds, we left you with the impression that the only kinds of bonds in which metals are ever involved are ionic bonds. For some metals, like the alkali metals of Group 1A, this is close enough to the truth to warrant no modifications. However, for many other metal ions, especially those of the transition metals and the post-transition metals, it is not. This is because the ions of many of these metals are able to behave as Lewis acids (i.e., as electron pair acceptors in the formation of coordinate covalent bonds). Thus, by participating in Lewis acid–base reactions they become *covalently* bonded to other atoms. Copper(II) ion is a typical example.

In aqueous solutions of copper(II) salts, such as $CuSO_4$ or $Cu(NO_3)_2$, the copper is not present as simple Cu^{2+} ions. Instead, each Cu^{2+} ion becomes bonded to six water molecules to give a pale blue ion with the formula $Cu(H_2O)_6^{2+}$ (see Figure 18.7). We call this species a **complex ion** because it is composed of a number of simpler species (i.e., it is *complex*, not simple). The chemical equation for the formation of the $Cu(H_2O)_6^{2+}$ ion is

$$Cu^{2+} + 6H_2O \longrightarrow Cu(H_2O)_6^{2+}$$

which can be diagrammed using Lewis structures as follows:



Cu^{2+}
Cu
2+
$Cu(H_2O)_6^{2+}$

Figure 18.7 | **The complex ion of Cu^{2+} and water.** A solution containing copper sulfate has a blue color because it contains the complex ion $Cu(H_2O)_6^{2+}$. *(Andy Washnik)*

■ Recall that a *Lewis base* is an electron pair donor in the formation of a coordinate covalent bond.

As you can see in this analysis, the Cu^{2+} ion accepts pairs of electrons from the water molecules, so Cu^{2+} is a Lewis acid and the water molecules are each Lewis bases.

The number of complex ions formed by metals, especially the transition metals, is enormous, and the study of the properties, reactions, structures, and bonding in complex ions like $Cu(H_2O)_6{}^{2+}$ has become an important specialty within chemistry. We will provide a more complete discussion of them in Chapter 22. For now, we will introduce you to some of the terminology that we use in describing these substances.

A Lewis base that attaches itself to a metal ion is called a **ligand** (from the Latin *ligare*, meaning "to bind"). Ligands can be neutral molecules with unshared pairs of electrons (e.g., H_2O), or they can be anions (e.g., Cl^- or OH^-). The atom in the ligand that actually provides the electron pair is called the **donor atom**, and the metal ion is the **acceptor**. The result of combining a metal ion with one or more ligands is a *complex ion*, or simply just a **complex**. The word "complex" avoids problems when the particle formed is electrically neutral, as sometimes happens. Compounds that contain complex ions are generally referred to as **coordination compounds** because the bonds in a complex ion can be viewed as coordinate-covalent bonds. Sometimes the complex itself is called a **coordination complex.**

■ According to Le Châtelier's principle, when the concentration of ammonia is high, the position of equilibrium in this reaction is shifted far to the right, so effectively all complex ions with water molecules are changed to those with ammonia molecules.

In an aqueous solution, the formation of a complex ion is really a reaction in which water molecules are replaced by other ligands. Thus, when NH_3 is added to a solution of copper ion, the water molecules in the $Cu(H_2O)_6{}^{2+}$ ion are replaced stepwise by molecules of NH_3 until the deeply blue complex $Cu(NH_3)_4{}^{2+}$ is formed (Figure 18.8). Each successive reaction is an equilibrium, so the entire chemical system involves many species and is quite complicated. Fortunately, when the ligand concentration is *large* relative to that of the metal ion, the concentrations of the intermediate complexes are very small and we can work only with the *overall* reaction for the formation of the final complex. Our study of complex ion equilibria will be limited to these situations. The equilibrium equation for the formation of $Cu(NH_3)_4{}^{2+}$, therefore, can be written as though the complex forms in one step.

$$Cu(H_2O)_6{}^{2+}(aq) + 4NH_3(aq) \rightleftharpoons Cu(NH_3)_4{}^{2+}(aq) + 6H_2O$$

We will simplify this equation for the purposes of dealing quantitatively with the equilibria by omitting the water molecules. (As in Chapter 15, it is appropriate to do this because the concentration of H_2O in aqueous solutions is taken to be effectively a constant and need not be included in mass action expressions.) In simplified form, we write the preceding equilibrium as follows:

$$Cu^{2+}(aq) + 4NH_3(aq) \rightleftharpoons Cu(NH_3)_4{}^{2+}(aq)$$

We have two goals here—namely, to study such equilibria themselves and to learn how they can be used to influence the solubilities of metal ion salts.

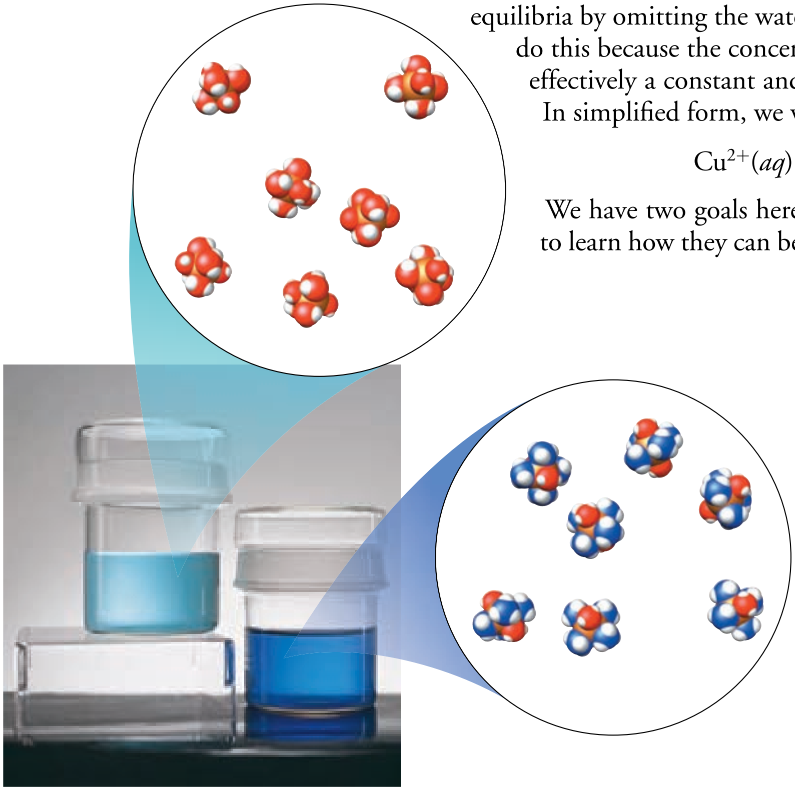


Figure 18.8 | **The complex ion of Cu^{2+} and ammonia.** Ammonia molecules displace water molecules from $Cu(H_2O)_6{}^{2+}$ (left) to give the deep blue $Cu(NH_3)_4{}^{2+}$ ion (right). In the molecular view we show two water molecules that are also weakly attached to the copper ion in the $Cu(NH_3)_4{}^{2+}$ cation. *(Andy Washnik)*

Formation Constants

When the chemical equation for the equilibrium is written so that the complex ion is the product, the equilibrium constant for the reaction is called the **formation constant, K_{form}**. The equilibrium law for the formation of $Cu(NH_3)_4^{2+}$ in the presence of excess NH_3, for example, is

$$\frac{[Cu(NH_3)_4^{2+}]}{[Cu^{2+}][NH_3]^4} = K_{form}$$

TOOLS

Formation constants of complex ions

Sometimes this equilibrium constant is called the **stability constant**. The larger its value, the greater is the concentration of the complex at equilibrium, and so the more stable is the complex.

Table 18.3 provides several more examples of complex ion equilibria and their associated equilibrium constants. (Additional examples are in Appendix C.) The most stable complex in the table, $Co(NH_3)_6^{3+}$, has the largest value of K_{form}.

Instability Constants

Some chemists prefer to describe the relative stabilities of complex ions differently. Their approach focuses attention on the *breakdown* of the complex, not its formation. Therefore, the associated equilibrium equation is written as the reverse of the formation of the complex. The equilibrium for the copper–ammonia complex would be written as follows, for example:

$$Cu(NH_3)_4^{2+}(aq) \rightleftharpoons Cu^{2+}(aq) + 4NH_3(aq)$$

The equilibrium constant for this equilibrium is called the **instability constant, K_{inst}:**

$$K_{inst} = \frac{[Cu^{2+}][NH_3]^4}{[Cu(NH_3)_4^{2+}]} = \frac{1}{K_{form}}$$

Notice that K_{inst} is the reciprocal of K_{form}. The K_{inst} is called an *instability* constant because the larger its value is, the more *unstable* the complex is. The data in the last column of Table 18.3 show this. The least stable complex in the table, $Co(NH_3)_6^{2+}$, has the largest value of K_{inst}.

Table 18.3 Formation Constants and Instability Constants for Some Complex Ions

Ligand	Equilibrium	K_{form}	K_{inst}
NH_3	$Ag^+ + 2NH_3 \rightleftharpoons Ag(NH_3)_2^+$	1.6×10^7	6.3×10^{-8}
	$Co^{2+} + 6NH_3 \rightleftharpoons Co(NH_3)_6^{2+}$	5.0×10^4	2.0×10^{-5}
	$Co^{3+} + 6NH_3 \rightleftharpoons Co(NH_3)_6^{3+}$	4.6×10^{33}	2.2×10^{-34}
	$Cu^{2+} + 4NH_3 \rightleftharpoons Cu(NH_3)_4^{2+}$	1.1×10^{13}	9.1×10^{-14}
	$Hg^{2+} + 4NH_3 \rightleftharpoons Hg(NH_3)_4^{2+}$	1.8×10^{19}	5.6×10^{-20}
F^-	$Al^{3+} + 6F^- \rightleftharpoons AlF_6^{3-}$	1×10^{20}	1×10^{-20}
	$Sn^{4+} + 6F^- \rightleftharpoons SnF_6^{2-}$	1×10^{25}	1×10^{-25}
Cl^-	$Hg^{2+} + 4Cl^- \rightleftharpoons HgCl_4^{2-}$	5.0×10^{15}	2.0×10^{-16}
Br^-	$Hg^{2+} + 4Br^- \rightleftharpoons HgBr_4^{2-}$	1.0×10^{21}	1.0×10^{-21}
I^-	$Hg^{2+} + 4I^- \rightleftharpoons HgI_4^{2-}$	1.9×10^{30}	5.3×10^{-31}
CN^-	$Fe^{2+} + 6CN^- \rightleftharpoons Fe(CN)_6^{4-}$	1.0×10^{24}	1.0×10^{-24}
	$Fe^{3+} + 6CN^- \rightleftharpoons Fe(CN)_6^{3-}$	1.0×10^{31}	1.0×10^{-31}

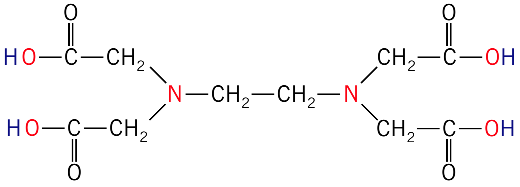
CHEMISTRY OUTSIDE THE CLASSROOM 18.1

No More Soap Scum—Complex Ions and Solubility

A problem that has plagued homeowners with hard water—water that contains low concentrations of divalent cations, especially Ca^{2+}—is the formation of insoluble deposits of "soap scum" as well as "hard water spots" on surfaces such as shower tiles, shower curtains, and bathtubs. These deposits form when calcium ions interact with large anions in soap to form precipitates and also when hard water that contains bicarbonate ion evaporates, causing the precipitation of calcium carbonate, $CaCO_3$.

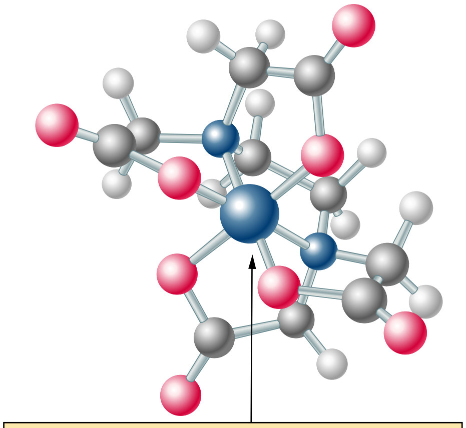
$$Ca^{2+}(aq) + 2HCO_3^-(aq) \longrightarrow CaCO_3(s) + CO_2(g) + H_2O$$

A variety of consumer products are sold that contain ingredients intended to prevent these precipitates from forming, and they accomplish this by forming complex ions with calcium ions, which has the effect of increasing the solubilities of the soap scum and calcium carbonate deposits. A principal ingredient in these products is an organic compound called *ethylenediaminetetraacetic* acid (mercifully abbreviated *EDTA*). The structure of the compound, which is also abbreviated as H_4EDTA to emphasize that it contains four acidic hydrogens that are part of carboxyl groups, is



H_4EDTA
Acidic hydrogens are shown in blue,
donor atoms are shown in red.

This molecule is an excellent complex-forming ligand; it contains a total of *six* donor atoms (in red) that can bind to a metal ion, enabling the ligand to wrap itself around the metal ion as illustrated above, right. (The usual colors are used to identify the various elements in the ligand.)



A metal ion surrounded octahedrally by all six donor atoms if H_4EDTA loses all of the acidic hydrogens.

One consumer product, called Clean Shower (Figure 1), contains H_4EDTA along with substances called surfactants. When the EDTA binds with calcium ions, it releases just two H^+ ions,

$$H_4EDTA(aq) + Ca^{2+}(aq) \longrightarrow CaH_2EDTA(aq) + 2H^+(aq)$$

The H^+ combine with anions of the soap to form neutral organic compounds called fatty acids that are usually not water soluble. The surfactants in the product, however, enable the fatty acids to dissolve, preventing the formation of precipitates. The Clean Shower product is sprayed on the wet walls after taking a shower, forming the products just described. The next time you take a shower, the water washes away the soluble products, keeping soap scum from building up and keeping the shower walls clean.

CLEAN SHOWER

Figure 1 The product Clean Shower contains EDTA, which prevents the formation of soap scum and hard water spots in showers and on bathtubs. *(Andy Washnik)*

18.5 | Complexation and Solubility

The silver halides are extremely insoluble salts. The K_{sp} of AgBr at 25 °C, for example, is only 5.4×10^{-13}. In a saturated aqueous solution, the concentration of each ion of AgBr is only 7.3×10^{-7} mol L^{-1}. Suppose that we start with a saturated solution in which undissolved AgBr is present and equilibrium exists. Now, suppose that we begin to add aqueous ammonia to the system. Because NH_3 molecules bind strongly to silver ions, they begin to form $Ag(NH_3)_2^+$ with the trace amount of Ag^+ ions initially in solution. The reaction is

Complex ion equilibrium:

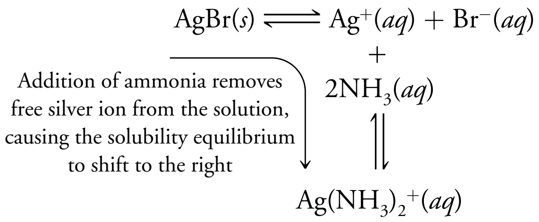
$$Ag^+(aq) + 2NH_3(aq) \rightleftharpoons Ag(NH_3)_2^+(aq) \qquad K_{form} = 1.6 \times 10^7$$

Because the forward reaction removes *uncomplexed* Ag^+ ions from solution, it upsets the solubility equilibrium:

Solubility equilibrium:

$$AgBr(s) \rightleftharpoons Ag^+(aq) + Br^-(aq) \qquad K_{sp} = 5.4 \times 10^{-13}$$

By withdrawing uncomplexed Ag^+ ions, the ammonia causes the solubility equilibrium to shift to the right to generate more Ag^+ ions from $AgBr(s)$. The way the two equilibria are related can be viewed as follows:



AgBr(s) ⇌ Ag+(aq) + Br−(aq)
+
2NH3(aq)
Addition of ammonia removes free silver ion from the solution, causing the solubility equilibrium to shift to the right
Ag(NH3)2+(aq)

Thus, adding ammonia causes more $AgBr(s)$ to dissolve—an example of Le Châtelier's principle at work. Our example illustrates the following general phenomenon:

> The solubility of a slightly soluble salt increases when one of its ions can be changed to a soluble complex ion.

To analyze what happens, lets put the two equilibria together:

Complex ion equilibrium:	$Ag^+(aq) + 2NH_3(aq) \rightleftharpoons Ag(NH_3)_2^+(aq)$
Solubility equilibrium:	$AgBr(s) \rightleftharpoons Ag^+(aq) + Br^-(aq)$
Sum of equilibria:	$AgBr(s) + 2NH_3(aq) \rightleftharpoons Ag(NH_3)_2^+(aq) + Br^-(aq)$

The equilibrium constant for the net overall reaction is written in the usual way. Again, the term for $[AgBr(s)]$ is omitted because it refers to a solid and so has a constant value:

$$K_c = \frac{[Ag(NH_3)_2^+][Br^-]}{[NH_3]^2}$$

Because we have added two equations to obtain a third equation, K_c for this expression is the product of K_{form} and K_{sp}. The values for K_{form} for $Ag(NH_3)_2^+$ and K_{sp} for AgBr are known, so by multiplying the two, we find the overall value of K_c for the silver bromide–ammonia system.

■ Recall that when equilibrium equations are added, their equilibrium constants are multiplied.

$$K_c = K_{form} \times K_{sp}$$
$$K_c = (1.6 \times 10^7)(5.4 \times 10^{-13})$$
$$= 8.0 \times 10^{-6}$$

This approach thus gives us a way to calculate the solubility of a sparingly soluble salt when a substance able to form a complex with the metal ion is put into its solution. Example 18.11 shows how this works.

Example 18.11

Calculating the Solubility of a Slightly Soluble Salt in the Presence of a Ligand

How many moles of AgBr can dissolve in 1.0 L of 1.0 M NH_3?

Analysis: Silver bromide is insoluble in water, but with the addition of NH_3, more AgBr can be dissolved. This question is asking us to use the K_{form} and the K_{sp} together to determine the amount of AgBr dissolved in water.

Assembling the Tools: A few preliminaries have to be done before we can take advantage of a concentration table. We need the overall balanced chemical equation and its associated equation for the equilibrium constant, which serve as our tools for dealing with these kinds of problems. The overall equilibrium is

$$AgBr(s) + 2NH_3(aq) \rightleftharpoons Ag(NH_3)_2^+(aq) + Br^-(aq)$$

The equation for K_c is

$$K_c = \frac{[Ag(NH_3)_2^+][Br^-]}{[NH_3]^2} = 8.0 \times 10^{-6} \qquad \text{(as calculated earlier)}$$

Next, we will need to use the concentration table. To do this, we imagine we are adding solid AgBr to the ammonia solution.

Before any reaction takes place, the concentration of NH_3 is 1.0 M and the concentration of $Ag(NH_3)_2^+$ is zero. The concentration of Br^- is also zero, because there is none of it in the ammonia solution.

If we define x as the molar solubility of the AgBr in the solution, then the concentrations of $Ag(NH_3)_2^+$ and Br^- both increase by x and the concentration of ammonia decreases by $2x$ (because of the coefficient of NH_3 in the balanced chemical equation).

The equilibrium values are obtained as usual by adding the initial and change rows. However, we need to note that letting the concentration of Br^- equal that of $Ag(NH_3)_2^+$ is valid because *and only because* K_{form} is such a large number. Essentially *all* Ag^+ ions that do dissolve from the insoluble AgBr are changed into the complex ion. There are relatively few uncomplexed Ag^+ ions in the solution, so the number of $Ag(NH_3)_2^+$ and Br^- ions in the solution are very nearly the same.

Solution: The concentration table is as follows.

	$AgBr(s)$	$+$	$2NH_3(aq)$	$\rightleftharpoons$	$Ag(NH_3)_2^+(aq)$	$+$	$Br^-(aq)$
Initial concentrations (M)			1.0		0		0
Change in concentrations caused by NH_3 (M)			$-2x$		$+x$		$+x$
Equilibrium concentrations (M)			$(1.0 - 2x)$		x		x

We've done all the hard work. Now all we need to do is substitute the values in the last row of the concentration table into the equation for K_c,

$$K_c = \frac{(x)(x)}{(1.0 - 2x)^2} = 8.0 \times 10^{-6}$$

This can be solved analytically by taking the square root of both sides, which gives

$$\frac{(x)}{(1.0 - 2x)} = \sqrt{8.0 \times 10^{-6}} = 2.8 \times 10^{-3}$$

Solving for x and rounding to the correct number of significant figures gives

$$x = 2.8 \times 10^{-3}$$

Because we've defined x as the molar solubility of AgBr in the ammonia solution, we can say that 2.8×10^{-3} mol of AgBr dissolves in 1.0 L of 1.0 M NH_3. (This is not very much, but in contrast, only 7.1×10^{-7} mol of AgBr dissolves in 1.0 L of pure water. Thus, AgBr is nearly 4000 times more soluble in the 1.0 M NH_3 than in pure water.)

■ **Is the Answer Reasonable?** Everything depends on the reasoning used in preparing the concentration table, particularly letting $-2x$ represent the change in the concentration of NH_3 as a result of the presence of AgBr and the formation of the complex. If you are comfortable with this, then the calculation should be straightforward.

Practice Exercises

18.20 | Calculate the solubility of silver chloride in 0.10 M NH_3 and compare it with its solubility in pure water. Refer to Table 18.1 for the K_{sp} for AgCl. (*Hint*: Assume that all of the Ag^+ from the AgCl becomes incorporated into $Ag(NH_3)_2{}^+$.)

18.21 | How many moles of NH_3 have to be added to 1.0 L of water to dissolve 0.20 mol of AgCl? The complex ion $Ag(NH_3)_2{}^+$ forms.

Summary

Solubility Equilibria for Salts. The mass action expression for a solubility equilibrium of a salt is called the **ion product**. It equals the product of the molar concentrations of its ions, each raised to a power equal to the subscript of the ion in the salt's formula. At a given temperature, the value of the ion product, Q, in a *saturated* solution of the salt equals a constant called the **solubility product constant** or $\boldsymbol{K_{sp}}$.

For solubility equilibria, the *common ion effect* is the ability of an ion of a soluble salt to suppress the solubility of a sparingly soluble compound that has the same (the "common") ion.

If soluble salts are mixed together in the same solution, a cation of one and an anion of another will precipitate if the ion product, Q, exceeds the solubility product constant of the salt formed from them.

Selective Precipitation. Metal sulfides are vastly more soluble in an acidic solution than in water. To express their solubility equilibria in acid, the **acid solubility constant** or $\boldsymbol{K_{spa}}$ is used. Several metal sulfides have such low values of K_{spa} that they are insoluble even at low pH. These **acid-insoluble sulfides** can thus be selectively separated from the **base-insoluble sulfides** by making the solution both quite acidic as well as saturated in H_2S. By adjusting the pH, salts of other weak acids, like the carbonate salts, can also be selectively precipitated.

Complex Ions of Metals. **Coordination compounds** contain **complex ions** (also called **complexes** or **coordination complexes**) formed from a metal ion and a number of ligands. **Ligands** are Lewis bases (electron pair donors) and may be electrically neutral or negatively charged. Water and ammonia are common neutral ligands. Metal ions often act as electron pair acceptors (i.e., as Lewis acids). The equilibrium constant for the formation of a metal–ligand complex in the presence of an excess of ligand is called the **formation constant,** $\boldsymbol{K_{form}}$, of the complex. The larger the value of K_{form}, the more stable is the complex. Salts whose cations form stable complexes, like Ag^+ salts whose cation forms a stable complex with ammonia, $Ag(NH_3)_2{}^+$, are made more soluble when the ligand is present.

TOOLS

Tools for Problem Solving The following tools were introduced in this chapter. Study them carefully so you can select the appropriate tool when needed.

Solubility product constant, $\boldsymbol{K_{sp}}$ (page 831)
We use K_{sp} to calculate the molar solubility of a salt either in pure water or in a solution that contains a common ion. Comparing K_{sp} with the ion product of a potential precipitating salt permits us to decide whether a precipitate will form.

Molar solubility (page 833)
This is used for calculating the value of K_{sp} for a salt. When calculating the solubility of a salt from K_{sp}, we let x represent the molar solubility in the concentration table.

Concentration table (page 833)

The concentration tables are the same as the concentration table tool in Chapter 15, only we are using them for insoluble salts in this chapter.

Predicting precipitation (page 841)

Compare Q with K_{sp} to determine whether a precipitate will form:

$$Q > K_{sp}, \text{ a precipitate forms}$$
$$Q \leq K_{sp}, \text{ a precipitate does } \textit{not} \text{ form}$$

Acid solubility product constant, K_{spa} (page 847)

Use K_{spa} data to calculate the solubility of a metal sulfide at a given pH. We can use K_{spa} data for two or more metal sulfides to calculate the pH at which one will selectively precipitate from a solution saturated in H_2S.

Combined K_a expression for a diprotic acid (page 852)

Combining expressions for K_{a_1} and K_{a_2} for a diprotic acid, H_2A, yields the equation

$$\frac{[H^+]^2[A^{2-}]}{[H_2A]} = K_a = K_{a_1} \times K_{a_2}$$

This equation can be used if (and only if) we know two of the three quantities in the combined mass action expression. This is a useful tool when working problems involving the selective precipitation of salts of diprotic acids where the concentration of the anion A^{2-} is controlled by adjusting the pH of the solution.

Formation constants of complex ions (page 857)

We can use them to make judgments concerning the relative stabilities of complexes. Along with K_{sp} values, we can use formation constants of complexes to determine the solubility of a sparingly soluble salt in a solution containing a ligand that's able to form a complex with the cation of the salt.

Review Questions

Solubility Products

18.1 What is the difference between an *ion product* and an *ion product constant*?

18.2 Use the following equilibrium to demonstrate why the K_{sp} expression does not include the concentration of $Ba_3(PO_4)_2$ in the denominator:

$$Ba_3(PO_4)_2(s) \rightleftharpoons 3Ba^{2+}(aq) + 2PO_4^{3-}(aq)$$

18.3 What is the common ion effect? How does Le Châtelier's principle explain it? Use the solubility equilibrium for AgCl and the addition of NaCl to the solution to illustrate the common ion effect.

18.4 With respect to K_{sp}, what conditions must be met if a precipitate is going to form in a solution?

18.5 What limits the accuracy and reliability of solubility calculations based on K_{sp} values?

18.6 Why do we *not* use K_{sp} values for soluble salts such as NaCl?

Selective Precipitation

18.7 Potassium oxide is readily soluble in water, but the resulting solution contains essentially no oxide ion. Explain, using an equation, what happens to the oxide ion.

18.8 What chemical reaction takes place when solid sodium sulfide is dissolved in water? Write the chemical equation.

18.9 Consider cobalt(II) sulfide.

(a) Write its solubility equilibrium and K_{sp} equation for a saturated solution in water. (Remember: There is no free sulfide ion in the solution.)

(b) Write its solubility equilibrium and K_{spa} equation for a saturated solution in aqueous acid.

18.10 Use Le Châtelier's principle to explain how adjusting the pH makes it possible to control the concentration of $C_2O_4^{2-}$ in a solution of oxalic acid, $H_2C_2O_4$.

18.11 Suppose you wanted to control the PO_4^{3-} concentration in a solution of phosphoric acid by controlling the pH of the solution. If you assume you know the H_3PO_4 concentration, what combined equation would be useful for this purpose?

18.12 If you had a solution with Ag^+, Co^{2+}, and Cu^{2+}, how could you separate the metal ions by selective precipitation?

Simultaneous and Complex Ion Equilibria

18.13 A solution of $MgBr_2$ can be changed to a solution of $MgCl_2$ by adding AgCl(*s*) and stirring the mixture well. In terms of the equilibria involved, explain how this happens.

18.14 On the basis of Le Châtelier's principle, explain how the addition of solid NH_4Cl to a beaker containing solid $Mg(OH)_2$ in contact with water is able to cause the $Mg(OH)_2$ to dissolve. Write equations for *all* of the chemical equilibria that exist in the solution after the addition of the NH_4Cl.

18.15 Using Le Châtelier's principle, explain how the addition of aqueous ammonia dissolves silver chloride. If HNO_3 is added after the AgCl has dissolved in the NH_3 solution, it causes AgCl to re-precipitate. Explain why.

18.16 For $PbCl_3^-$, $K_{form} = 2.5 \times 10^1$. If a solution containing this complex ion is diluted with water, $PbCl_2$ precipitates. Write the equations for the equilibria involved and use them together with Le Châtelier's principle to explain how this happens.

18.17 Which of the following will be more soluble if acid is added to the mixture? Will adding base increase the solubility of any of these? Are any of their solubilities independent of the pH of the solution? **(a)** ZnS, **(b)** $Ca(OH)_2$, **(c)** $MgCO_3$, **(d)** AgCl, **(e)** PbF_2

Review Problems

Solubility Products

18.18 Write the K_{sp} expressions for each of the following compounds:

(a) CaF_2 **(c)** $PbSO_4$ **(e)** PbI_2

(b) Ag_2CO_3 **(d)** $Fe(OH)_3$ **(f)** $Cu(OH)_2$

18.19 Write the K_{sp} expressions for each of the following compounds:

(a) AgI **(c)** $PbCrO_4$ **(e)** $ZnCO_3$

(b) Ag_3PO_4 **(d)** $Al(OH)_3$ **(f)** $Zn(OH)_2$

Determining K_{sp}

18.20 In water, the solubility of lead(II) chloride is 0.016 *M*. Use this information to calculate the value of K_{sp} for $PbCl_2$.

18.21 The solubility of zinc oxalate is 7.9×10^{-3} *M*. Calculate the K_{sp} for ZnC_2O_4.

18.22 Barium sulfate is so insoluble that it can be swallowed without significant danger, even though Ba^{2+} is toxic. At 25 °C, 1.00 L of water dissolves only 0.00245 g of $BaSO_4$. Calculate the molar solubility and K_{sp} for $BaSO_4$.

18.23 A student found that a maximum of 0.800 g silver acetate is able to dissolve in 100.0 mL of water. What is the molar solubility and the K_{sp} for this salt?

OH **18.24** A student evaporated 100.0 mL of a saturated BaF_2 solution and found the solid BaF_2 she recovered weighed 0.132 g. From these data, calculate K_{sp} for BaF_2.

18.25 A student prepared a saturated solution of $CaCrO_4$ and found that when 156 mL of the solution was evaporated, 0.649 g of $CaCrO_4$ was left behind. What is the value of K_{sp} for this salt?

18.26 At 25 °C, the molar solubility of silver phosphate is 1.8×10^{-5} mol L^{-1}. Calculate K_{sp} for this salt.

18.27 The molar solubility of barium phosphate in water at 25 °C is 1.4×10^{-8} mol L^{-1}. What is the value of K_{sp} for this salt?

Using K_{sp} to Calculate Solubilities

18.28 Which compound is more soluble in water, $ZnCO_3$ or $MgCO_3$?

18.29 Which compound is more soluble in water, $BaSO_4$ or $SrCO_3$?

18.30 What is the molar solubility of $PbBr_2$ in water?

18.31 What is the molar solubility of Ag_2CrO_4 in water?

18.32 Calculate the molar solubility of $Zn(CN)_2$ in water. (Ignore the reaction of the CN^- ion with water.)

18.33 Calculate the molar solubility of PbF_2 in water. (Ignore the reaction of the F^- ion with water.)

18.34 At 25 °C, the value of K_{sp} for LiF is 1.8×10^{-3}, and that for BaF_2 is 1.7×10^{-6}. Which salt, LiF or BaF_2, has the larger molar solubility in water? Calculate the solubility of each in units of mol L^{-1}.

18.35 At 25 °C, the value of K_{sp} for AgCN is 6.0×10^{-17} and that for $Zn(CN)_2$ is 3×10^{-16}. In terms of grams per 100 mL of solution, which salt is more soluble in water?

18.36 A salt whose formula is MX has a K_{sp} equal to 3.2×10^{-10}. Another sparingly soluble salt, MX_3, must have what value of K_{sp} if the molar solubilities of the two salts are to be identical?

18.37 A salt having a formula of the type M_2X_3 has $K_{sp} = 2.2 \times 10^{-20}$. Another salt, M_2X, has to have what K_{sp} value if M_2X has twice the molar solubility of M_2X_3?

18.38 Calcium sulfate is found in plaster. At 25 °C the value of K_{sp} for $CaSO_4$ is 4.9×10^{-5}. What is the calculated molar solubility of $CaSO_4$ in water?

18.39 Chalk is $CaCO_3$, and at 25 °C its $K_{sp} = 3.4 \times 10^{-9}$. What is the molar solubility of $CaCO_3$? How many grams of $CaCO_3$ dissolve in 0.100 L of aqueous solution? (Ignore the reaction of CO_3^{2-} with water.)

Common Ion Effect

18.40 It was found that the molar solubility of $BaSO_3$ in 0.10 *M* $BaCl_2$ is 8.0×10^{-6} *M*. What is the value of K_{sp} for $BaSO_3$?

18.41 The molar solubility of Ag_2CrO_4 in 0.10 *M* Na_2CrO_4 is 1.7×10^{-6} *M*. What is the value of K_{sp} for Ag_2CrO_4?

ILW **18.42** Copper(I) chloride has $K_{sp} = 1.7 \times 10^{-7}$. Calculate the molar solubility of copper(I) chloride in **(a)** pure water, **(b)** 0.0200 *M* HCl solution, **(c)** 0.200 *M* HCl solution, and **(d)** 0.150 *M* $CaCl_2$ solution.

18.43 Gold(III) chloride has $K_{sp} = 3.2 \times 10^{-25}$. Calculate the molar solubility of gold(III) chloride in **(a)** pure water, **(b)** 0.010 *M* HCl solution, **(c)** 0.010 *M* $MgCl_2$ solution, and **(d)** 0.010 *M* $Au(NO_3)_3$ solution.

18.44 Calculate the molar solubility of $Mg(OH)_2$ in a solution that is basic with a pH of 12.50.

18.45 Calculate the molar solubility of $Al(OH)_3$ in a solution that is slightly basic with a pH of 9.50.

18.46 What is the highest concentration of Pb^{2+} that can exist in a solution of 0.10 *M* HCl?

18.47 Will lead(II) bromide be less soluble in 0.10 *M* $Pb(C_2H_3O_2)_2$ or in 0.10 *M* NaBr?

18.48 Calculate the molar solubility of Ag_2CrO_4 at 25 °C in **(a)** 0.200 *M* $AgNO_3$ and **(b)** 0.200 *M* Na_2CrO_4. For Ag_2CrO_4 at 25 °C, $K_{sp} = 1.1 \times 10^{-12}$.

18.49 What is the molar solubility of $Mg(OH)_2$ in **(a)** 0.20 *M* NaOH and **(b)** 0.20 *M* $MgSO_4$? For $Mg(OH)_2$, $K_{sp} = 5.6 \times 10^{-12}$.

***18.50** In an experiment, 2.20 g of NaOH(*s*) is added to 250 mL of 0.10 *M* $FeCl_2$ solution. What mass of $Fe(OH)_2$ will be formed? What will the molar concentration of Fe^{2+} be in the final solution?

***18.51** Suppose that 1.75 g of NaOH(*s*) is added to 250 mL of 0.10 *M* $NiCl_2$ solution. What mass, in grams, of $Ni(OH)_2$ will be formed? What will be the pH of the final solution? For $Ni(OH)_2$, $K_{sp} = 5.5 \times 10^{-16}$.

18.52 What is the molar solubility of $Fe(OH)_2$ in a buffer that has a pH of 9.50?

18.53 What is the molar solubility of $Ca(OH)_2$ in **(a)** 0.10 *M* $CaCl_2$ and **(b)** 0.10 *M* NaOH?

Precipitation

18.54 Does a precipitate of $PbCl_2$ form when 0.0150 mol of $Pb(NO_3)_2$ and 0.0120 mol of NaCl are dissolved in 1.00 L of solution?

18.55 Silver acetate, $AgC_2H_3O_2$, has $K_{sp} = 2.3 \times 10^{-3}$. Does a precipitate form when 0.015 mol of $AgNO_3$ and 0.25 mol of $Ca(C_2H_3O_2)_2$ are dissolved in a total volume of 1.00 L of solution?

ILW **18.56** Does a precipitate of $PbBr_2$ form if 50.0 mL of 0.0100 *M* $Pb(NO_3)_2$ is mixed with **(a)** 50.0 mL of 0.0100 *M* KBr and **(b)** 50.0 mL of 0.100 *M* NaBr?

18.57 Would a precipitate of silver acetate form if 22.0 mL of 0.100 *M* $AgNO_3$ were added to 45.0 mL of 0.0260 *M* $NaC_2H_3O_2$? For $AgC_2H_3O_2$, $K_{sp} = 2.3 \times 10^{-3}$.

18.58 Suppose 50.0 mL each of 0.0100 *M* solutions of NaBr and $Pb(NO_3)_2$ are poured together. Does a precipitate form? If so, calculate the molar concentrations of the ions at equilibrium.

18.59 If a solution of 0.10 *M* Mn^{2+} and 0.10 *M* Cd^{2+} is gradually made basic, what will the concentration of Cd^{2+} be when $Mn(OH)_2$ just begins to precipitate? Assume no change in the volume of the solution.

Selective Precipitation

18.60 Both AgCl and AgI are very sparingly soluble salts, but the solubility of AgI is much less than that of AgCl, as can be seen by their K_{sp} values. Suppose that a solution contains both Cl^- and I^- with $[Cl^-] = 0.050$ *M* and $[I^-] = 0.050$ *M*. If solid $AgNO_3$ is added to 1.00 L of this mixture (so that no appreciable change in volume occurs), what is the value of $[I^-]$ when AgCl first begins to precipitate?

18.61 Suppose that Na_2SO_4 is added gradually to 100.0 mL of a solution that contains both Ca^{2+} ion (0.15 *M*) and Sr^{2+} ion (0.15 *M*). **(a)** What will the Sr^{2+} concentration be (in mol L^{-1}) when $CaSO_4$ just begins to precipitate? **(b)** What percentage of the strontium ion has precipitated when $CaSO_4$ just begins to precipitate?

ILW OH **18.62** What value of $[H^+]$ and what pH permits the selective precipitation of the sulfide of just one of the two metal ions in a solution that has a concentration of 0.010 *M* Pb^{2+} and 0.010 *M* Co^{2+}?

18.63 What pH would yield the maximum separation of Mn^{2+} from Sn^{2+} in a solution that is 0.010 *M* in Mn^{2+}, 0.010 *M* in Sn^{2+}, and saturated in H_2S? (Assume the green form of MnS in Table 18.2.)

18.64 What range of pH would permit the selective precipitation of Cu^{2+} as $Cu(OH)_2$ from a solution that contains 0.10 *M* Cu^{2+} and 0.10 *M* Mn^{2+}? For $Mn(OH)_2$, $K_{sp} = 1.6 \times 10^{-13}$, and for $Cu(OH)_2$, $K_{sp} = 4.8 \times 10^{-20}$.

18.65 Kidney stones often contain insoluble calcium oxalate, CaC_2O_4, which has a $K_{sp} = 2.3 \times 10^{-9}$. Calcium oxalate is considerably less soluble than magnesium oxalate, MgC_2O_4, which has a $K_{sp} = 4.8 \times 10^{-6}$. Suppose a solution contained both Ca^{2+} and Mg^{2+} at a concentration of 0.10 *M*. What pH would be required to achieve maximum separation of these ions by precipitation of CaC_2O_4 if the solution also contains oxalic acid, $H_2C_2O_4$ at a concentration of 0.10 *M*? For $H_2C_2O_4$, $K_{a_1} = 6.5 \times 10^{-2}$ and $K_{a_2} = 6.1 \times 10^{-5}$.

***18.66** A chemist has a solution containing Ag^+ and Ni^{2+} and would like to separate them by precipitating one of the metals by forming the carbonate of that metal. If carbon dioxide is bubbled into the solution to make a saturated $CO_2(aq)$ solution, approximately 0.030 *M*, in what pH range would it be possible to precipitate the silver ion as silver(I) carbonate and leave the nickel(II) ions in solution?

***18.67** In the metal plating industry, the waste is often contaminated with Zn^{2+} and Ni^{2+}. In order to save the metals, they are recovered by precipitating them as the carbonate salts. In what pH range would it be possible to separate and collect the zinc(II) ions and then the nickel(II) ions? The concentration of CO_2 is 0.030 *M*.

Complex Ion Equilibria

18.68 Write the chemical equilibria and equilibrium laws that correspond to K_{form} for the following complexes:

(a) $CuCl_4^{2-}$ **(b)** AgI_2^- **(c)** $Cr(NH_3)_6^{3+}$

18.69 Write the chemical equilibria and equilibrium laws that correspond to K_{form} for the following complexes:

(a) $Ag(S_2O_3)_2^{3-}$ **(b)** $Zn(NH_3)_4^{2+}$ **(c)** SnS_3^{2-}

OH 18.70 Write equilibria that correspond to K_{form} for each of the following complex ions and write the equations for K_{form}:

(a) $Co(NH_3)_6^{3+}$ **(b)** HgI_4^{2-} **(c)** $Fe(CN)_6^{4-}$

18.71 Write the equilibria that are associated with the equations for K_{form} for each of the following complex ions. Write also the equations for the K_{form} of each.

(a) $Hg(NH_3)_4^{2+}$ **(b)** SnF_6^{2-} **(c)** $Fe(CN)_6^{3-}$

18.72 Write equilibria that correspond to K_{inst} for each of the following complex ions and write the equations for K_{inst}:

(a) $Co(NH_3)_6^{3+}$ **(b)** HgI_4^{2-} **(c)** $Fe(CN)_6^{4-}$

18.73 Write the equilibria that are associated with the equations for K_{inst} for each of the following complex ions. Write also the equations for the K_{inst} of each.

(a) $Hg(NH_3)_4^{2+}$ **(b)** SnF_6^{2-} **(c)** $Fe(CN)_6^{3-}$

18.74 For $PbCl_3^-$, $K_{form} = 2.5 \times 10^1$. Use this information plus the K_{sp} for $PbCl_2$ to calculate K_c for the follwing reaction:

$$PbCl_2(s) + Cl^-(aq) \rightleftharpoons PbCl_3^-(aq)$$

18.75 The overall formation constant for $Ag(CN)_2^-$ equals 5.5×10^{18}, and the K_{sp} for AgCN equals 6.0×10^{-17}. Calculate K_c for the following reaction:

$$AgCN(s) + CN^-(aq) \rightleftharpoons Ag(CN)_2^-(aq)$$

18.76 How many grams of solid NaCN have to be added to 1.2 L of water to dissolve 0.11 mol of $Fe(OH)_3$ in the form of $Fe(CN)_6^{3-}$? Use data as needed from Tables 18.1 and 18.3. (For simplicity, ignore the reaction of CN^- ion with water.)

18.77 In photography, unexposed silver bromide is removed from film by soaking the film in a solution of sodium thiosulfate, $Na_2S_2O_3$. Silver ion forms a soluble complex with thiosulfate ion, $S_2O_3^{2-}$, which has the formula $Ag(S_2O_3)_2^{3-}$, and formation of the complex causes the AgBr in the film to dissolve. The $Ag(S_2O_3)_2^{3-}$complex has $K_{form} = 2.0 \times 10^{13}$. How many grams of AgBr ($K_{sp} = 5.4 \times 10^{-13}$) will dissolve in 125 mL of 1.20 *M* $Na_2S_2O_3$ solution?

18.78 Silver iodide is very insoluble and can be difficult to remove from glass apparatus, but it forms a relatively stable complex ion, AgI_2^- ($K_{form} = 1 \times 10^{11}$), that makes AgI fairly soluble in a solution containing I^-. When a solution containing the AgI_2^- ion is diluted with water, AgI precipitates. Explain why this happens in terms of the equilibria that are involved. How many grams of AgI will dissolve in 0.100 L of 1.0 *M* KI solution?

18.79 Silver forms a sparingly soluble iodide salt, AgI, and it also forms a soluble iodide complex, AgI_2^- ($K_{form} = 1 \times 10^{11}$). How many grams of potassium iodide must be added to 0.100 L of water to dissolve 0.020 mol of AgI? (*Hint*: Be sure to include *all* of the iodide that's added to the solution.)

18.80 The formation constant for $Ag(CN)_2^-$ equals 5.3×10^{18}. Use the data in Table 18.1 to determine the molar solubility of AgI in 0.010 *M* KCN solution.

18.81 Suppose that some dipositive cation, M^{2+}, is able to form a complex ion with a ligand, *L*, by the following balanced equation:

$$M^{2+} + 2L \rightleftharpoons M(L)_2^{2+}$$

The cation also forms a sparingly soluble salt, MCl_2. In which of the following circumstances would a given quantity of ligand be more able to bring larger quantities of the salt into solution? Explain and justify the calculation involved.

(a) $K_{form} = 1 \times 10^2$ and $K_{sp} = 1 \times 10^{-15}$

(b) $K_{form} = 1 \times 10^{10}$ and $K_{sp} = 1 \times 10^{-20}$

18.82 The molar solubility of $Zn(OH)_2$ in 1.0 *M* NH_3 is 5.7×10^{-3} mol L^{-1}. Determine the value of the instability constant of the complex ion, $Zn(NH_3)_4^{2+}$. Ignore the reaction, $NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$.

OH 18.83 Calculate the molar solubility of $Cu(OH)_2$ in 2.0 *M* NH_3. (For simplicity, ignore the reaction of NH_3 as a base.)

Additional Exercises

***18.84** What ratio of K_{sp} values will allow for the use of selective precipitation to separate two ionic compounds in which the less soluble one has less than 0.01% remaining when the more soluble one begins to precipitate? To make the calculation easier, assume that both compounds have one-to-one ratios of cation to anion.

***18.85** A student had a solution that contained Pb^{2+}, Ni^{2+}, and Cd^{2+} and wanted to separate the ions. The student added H_2S and acidified the solution to pH 0.5. The precipitate was collected and then the student raised the pH to 8.0 and another solid precipitated. Finally, the student added HCl, expecting to collect lead(II) chloride. Was the student able to collect the $PbCl_2$? What was in the first and second precipitates?

18.86 Magnesium hydroxide, $Mg(OH)_2$, found in milk of magnesia, has a solubility of 7.05×10^{-3} g L^{-1} at 25 °C. Calculate K_{sp} for $Mg(OH)_2$.

18.87 Does iron(II) sulfide dissolve in 8 *M* HCl? Perform the calculations that prove your answer.

18.88 In an aqueous suspension of $Ca(OH)_2$, the only other component is water. Use K_{sp} to estimate the pH of the suspension.

***18.89** Suppose that 25.0 mL of 0.10 *M* HCl is added to 1.000 L of saturated $Mg(OH)_2$ in contact with more than enough $Mg(OH)_2(s)$ to react with all of the HCl. After reaction has ceased, what will the molar concentration of Mg^{2+} be? What will the pH of the solution be?

OH ***18.90** Solid $Mn(OH)_2$ is added to a solution of 0.100 *M* $FeCl_2$. After reaction, what will be the molar concentrations of Mn^{2+} and Fe^{2+} in the solution? What will be the pH of the solution? For $Mn(OH)_2$, $K_{sp} = 1.6 \times 10^{-13}$.

***18.91** Suppose that 50.0 mL of 0.12 *M* $AgNO_3$ is added to 50.0 mL of 0.048 *M* NaCl solution. **(a)** What mass of AgCl will form? **(b)** Calculate the final concentrations of all of the ions in the solution that is in contact with the precipitate. **(c)** What percentage of the Ag^+ ions have precipitated?

***18.92** A sample of hard water was found to have 278 ppm Ca^{2+} ion. Into 1.00 L of this water, 1.00 g of Na_2CO_3 was dissolved. What is the new concentration of Ca^{2+} in parts per million? (Assume that the addition of Na_2CO_3 does not change the volume, and assume that the density of the aqueous solutions involved are all 1.00 g mL^{-1}.)

***18.93** What value of $[H^+]$ and what pH would allow the selective separation of the carbonate of just one of the two metal ions in a solution that has a concentration of 0.010 *M* La^{3+} and 0.010 *M* Pb^{2+}? For $La_2(CO_3)_3$, $K_{sp} = 4.0 \times 10^{-34}$; for $PbCO_3$, $K_{sp} = 7.4 \times 10^{-14}$. A saturated solution of CO_2 in water has a concentration of H_2CO_3 equal to 3.3×10^{-2} *M*.

***18.94** When solid NH_4Cl is added to a suspension of $Mg(OH)_2(s)$, some of the $Mg(OH)_2$ dissolves.

(a) Write equations for *all* of the chemical equilibria that exist in the solution after the addition of the NH_4Cl.

(b) How many moles of NH_4Cl must be added to 1.0 L of a suspension of $Mg(OH)_2$ to dissolve 0.10 mol of $Mg(OH)_2$?

(c) What is the pH of the solution after the 0.10 mol of $Mg(OH)_2$ has dissolved in the solution containing the NH_4Cl?

***18.95** After solid $CaCO_3$ was added to a slightly basic solution, the pH was measured to be 8.50. What was the molar solubility of $CaCO_3$ in this solution?

18.96 What is the molar solubility of $Fe(OH)_3$ in water? (*Hint*: You have to take into account the self-ionization of water.)

***18.97** In Example 18.11 (page 860) we say, "there are relatively few uncomplexed Ag^+ ions in the solution." Calculate the molar concentration of Ag^+ ion actually left after the complex forms as described in Example 18.11.

***18.98** What are the concentrations of Pb^{2+}, Br^-, and I^- in an aqueous solution that's in contact with both PbI_2 and $PbBr_2$?

***18.99** Will a precipitate form in a solution made by dissolving 1.0 mol of $AgNO_3$ and 1.0 mol $HC_2H_3O_2$ in 1.0 L of solution? For $AgC_2H_3O_2$, $K_{sp} = 2.3 \times 10^{-3}$, and for $HC_2H_3O_2$, $K_a = 1.8 \times 10^{-5}$.

***18.100** How many grams of solid sodium acetate must be added to 0.200 L of a solution containing 0.200 *M* $AgNO_3$ and 0.10 *M* nitric acid to cause silver acetate to begin to precipitate? For $HC_2H_3O_2$, $K_a = 1.8 \times 10^{-5}$, and for $AgC_2H_3O_2$, $K_{sp} = 2.3 \times 10^{-3}$.

***18.101** How many grams of solid potassium fluoride must be added to 200 mL of a solution that contains 0.20 *M* $AgNO_3$ and 0.10 *M* acetic acid to cause silver acetate to begin to precipitate? For HF, $K_a = 6.5 \times 10^{-4}$; for $HC_2H_3O_2$, $K_a = 1.8 \times 10^{-5}$; and for $AgC_2H_3O_2$, $K_{sp} = 2.3 \times 10^{-3}$.

***18.102** What is the molar solubility of $Mg(OH)_2$ in 0.10 *M* NH_3 solution? Remember that NH_3 is a weak base.

***18.103** If 100 mL of 2.0 *M* NH_3 is added to 0.400 L of a solution containing 0.10 *M* Mn^{2+} and 0.10 *M* Sn^{2+}, what minimum number of grams of HCl would have to be added to the mixture to prevent $Mn(OH)_2$ from precipitating? For $Mn(OH)_2$, $K_{sp} = 1.6 \times 10^{-13}$. Assume that virtually all of the tin is precipitated as $Sn(OH)_2$ by the following reaction:

$$Sn^{2+}(aq) + 2NH_3(aq) + 2H_2O \longrightarrow Sn(OH)_2(s) + 2NH_4{}^+(aq)$$

*__18.104__ What is the molar concentration of Cu^{2+} ion in a solution prepared by mixing 0.50 mol of NH_3 and 0.050 mol of $CuSO_4$ in 1.00 L of solution? For NH_3, $K_b = 1.8 \times 10^{-5}$; for $Cu(OH)_2$, $K_{sp} = 4.8 \times 10^{-20}$; and for $Cu(NH_3)_4{}^{2+}$, $K_{form} = 4.8 \times 10^{12}$.

*__18.105__ On the basis of the K_{sp} of $Al(OH)_3$, what would be the pH of a mixture consisting of solid $Al(OH)_3$ mixed with pure water? (Assume 100% dissociation of the aluminum hydroxide.)

*__18.106__ The compound EDTA is used to remove soap scum, as it was described in the *Chemistry Outside the Classroom 18.1.* It has also been used to treat heavy metal poisoning, especially lead and mercury poisoning. The reaction of lead with EDTA is

$$Pb^{2+}(aq) + EDTA^{4-}(aq) \rightleftharpoons PbEDTA^{2-}(aq) \qquad K = 1.1 \times 10^{18}$$

If a 1.0 L solution of 0.15 M $Pb(NO_3)_2$ containing 0.10 M $EDTA^{-4}$ is at a pH of 12.50, will $Pb(OH)_2$ precipitate?

*__18.107__ A chemist has a solution that contains a mixture of the following metal ions: Cu^{2+}, Co^{2+}, Ba^{2+}, Pb^{2+}, Ag^{+}, Mn^{2+}, Ca^{2+}, and Bi^{3+}. How can these ions be separated? Can all of them be separated? Which ones cannot be separated from each other?

18.108 You are given a sample containing NaCl(aq) and NaBr(aq), both with concentrations of 0.020 M. Some of the figures at the right represent a series of snapshots of what molecular-level views of the sample would show as a 0.200 M $Pb(NO_3)_2(aq)$ solution is slowly added. In these figures, Br^- is red-brown, and Cl^- is green. Also, spectator ions are not shown, nor are ions whose concentrations are much less than the other ions. The K_{sp} constants for $PbCl_2$ and $PbBr_2$ are 1.7×10^{-5} and 6.6×10^{-6}, respectively.

(1) Arrange the figures in a time sequence to show what happens as the lead(II) nitrate solution is added, excluding any that do not "make sense."

(2) Explain why you excluded any figures that did not belong in the observed time sequence.

Multi-Concept Problems

*__18.109__ What is the age of a stalagmite, if it has accumulated from a saturated $CaCO_3$ solution dropping at a rate of 1 drop per second? The stalagmite is a cone 10 ft in diameter and 16 ft high. The density of $CaCO_3$ is 2.71 g cm^{-3}. Assume that there are 10 drops of water in one milliliter of water and that the water evaporates when it hits the stalagmite.

*__18.110__ In modern construction, walls and ceilings are constructed of "drywall," which consists of plaster sandwiched between sheets of heavy paper. Plaster is composed of calcium sulfate, $CaSO_4 \cdot 2H_2O$. Suppose you had a leak in a water pipe that was dripping water on a drywall ceiling 1/2 in. thick at a rate of 2.00 L per day. Use the K_{sp} of calcium sulfate to estimate how many days it would take to dissolve a hole 1.0 cm in diameter. Assume the density of the plaster is 0.97 g cm^{-3}.

*__18.111__ How many milliliters of 0.10 M HCl would have to be added to 100 mL of a saturated solution of $PbCl_2$ in contact with 50.0 g of solid $PbCl_2$ to reduce the Pb^{2+} concentration to 0.0050 M?

*__18.112__ Marble is composed primarily of $CaCO_3$, a slightly soluble salt. Unfortunately, it is attacked by the acid in acid rain. What is the solubility of $CaCO_3$ in rain water (pH = 5.6) and acid rain (pH = 4.20)?

*__18.113__ The pH of a saturated solution of $Mg(OH)_2$ is 9.8. Determine the K_{sp} for $Mg(OH)_2$.

*__18.114__ The osmotic pressure of a saturated solution of $NiCO_3$ is 13 torr at 25 °C. From this information, calculate the K_{sp} for $NiCO_3$. Ignore the reaction of the carbonate ion with water.

Exercises in Critical Thinking

18.115 Consider mercury(II) sulfide, HgS, which has a solubility product of 2×10^{-53}. Suppose some solid HgS was added to 1.0 L of water. How many ions of Hg^{2+} and S^{2-} are present in the water when equilibrium is reached? If your answer is accurate, is there a true equilibrium between HgS(*s*) and the ions in the solution? Explain your answer.

18.116 If aqueous ammonia is added gradually to a solution of copper sulfate, a pale blue precipitate forms that then dissolves to give a deep blue solution. Describe the chemical reactions that take place during these changes.

18.117 From a practical standpoint, can you effectively separate Pb^{2+} and Sr^{2+} ions by selective precipitation of their sulfates? Support your conclusions using calculations.

18.118 A salt with the formula of MX_2, and a molar mass of approximately 200, is slightly soluble in water. Estimate the minimum reliable mass you can determine on your laboratory balance. Use that estimate to determine the smallest value of the solubility product of MX_2 that could be determined by evaporating a liter of a solution that is saturated in MX_2.

18.119 In older textbooks, the solubility equilibrium for lead(II) sulfide was written as $PbS(s) \rightleftharpoons Pb^{2+}(aq) + S^{2-}(aq)$, with $K_{sp} = 3 \times 10^{-28}$. Calculate the solubility of lead(II) sulfide using K_{sp} (assuming no reaction of S^{2-} with water) and with K_{spa}. Is there a difference between the two answers? Discuss the results of your calculations.

18.120 Suppose two silver wires, one coated with silver chloride and the other coated with silver bromide, are placed in a beaker containing pure water. Over time, what if anything will happen to the compositions of the coatings on the two wires? Justify your answer.

19.1 | First Law of Thermodynamics

19.2 | Spontaneous Change

19.3 | Entropy

19.4 | Second Law of Thermodynamics

19.5 | Third Law of Thermodynamics

19.6 | Standard Free Energy Change, $\Delta G°$

19.7 | Maximum Work and ΔG

19.8 | Free Energy and Equilibrium

19.9 | Equilibrium Constants and $\Delta G°$

19.10 | Bond Energies

Invented at Bell Laboratories in 1945, the drinking toy bird in this photo will suddenly tilt itself forward until its beak dips into a glass of water. When it apparently satisfies its thirst, it tilts back to an erect position. Soon it gets "thirsty" again and repeats the process, seemingly endlessly. In the cycle, the drinking bird absorbs water into the felt material on its head. The water, which is relatively warm, causes the dichloromethane, CH_2Cl_2, liquid inside the bird to evaporate slightly, pushing liquid toward the tail. When enough dichloromethane reaches the tail, the bird "stands up." When the bird is in the erect position the water evaporates from the felt head, causing some of the dichloromethane to condense. This creates a slight vacuum that draws liquid toward the head, and the bird dips down for another drink. Our bird is an example of a thermodynamic cycle (actually a heat engine) and the motions that can be generated by the flow of heat. Chapter 7 taught us about heat energy, and Chapters 11 and 12 taught the properties of gases and phase changes. This chapter brings many of these ideas together and extends them to consider criteria for spontaneous reactions, chemical equilibrium, and work that can be extracted from chemical reactions. (Corbis/SuperStock)

This Chapter in Context

The chemistry we observe in our world is controlled both by what *can* happen and what *cannot*. For example, hydrocarbon fuels such as octane (C_8H_{18}) *can* burn, forming CO_2 and H_2O and releasing heat. When combustion reactions are started, they proceed *spontaneously* (i.e., on their own, without further assistance), and we use them to provide energy to move vehicles, generate electricity, and heat homes and offices. On the other hand, if we mix CO_2 and H_2O, there is nothing we can do to entice them to react spontaneously to form hydrocarbons. These reactions *cannot* take place on their own. If they could, our problems with fossil fuel supplies and greenhouse gas production could easily be solved.

Observations like those described above raise the fundamental question, What determines whether or not a chemical reaction is possible when substances are combined? The answer to this question is found in the study of thermodynamics, which expands on topics introduced in Chapter 7—energy and chemical change. As you will see, not only will we be able to use thermodynamics to determine the possibility of reaction, but also we will find another explanation of chemical equilibrium and another way of determining numerical values for equilibrium constants.

19.1 | First Law of Thermodynamics

■ *Thermo* implies heat, *dynamics* implies movement.

Chemical thermodynamics is the study of the role of energy in chemical changes and in determining the behavior of materials. It is based on a few laws that summarize centuries of experimental observation. Each law is a statement about relationships between energy, heat, work, and temperature. Because the laws manifest themselves in so many different ways and underlie so many different phenomena, there are many alternative but equivalent ways to state them. For ease of reference, the laws are identified by number and are called the first law, the second law, and the third law of thermodynamics.

The **first law of thermodynamics**, which was discussed in Chapter 7, states that internal energy may be transferred as heat or work but it cannot be created or destroyed. This law, you recall, serves as the foundation for Hess's law, which we used in our computations involving enthalpy changes in Chapter 7. Let's review the first law in more detail.

Recall that the **internal energy** of a system, which is given the symbol E, is the system's total energy—the sum of all the kinetic and potential energies of its particles. For a chemical reaction, a change in the internal energy, ΔE, is defined as

$$\Delta E = E_{\text{products}} - E_{\text{reactants}}$$

Thus, ΔE is positive if energy flows into a system and negative if energy flows out.

The first law of thermodynamics considers two ways by which energy can be exchanged between a system and its surroundings. One is by the absorption or release of heat, which is given the symbol q. The other involves work, w. If *work is done on a system*, as in the compression of a gas, the system gains and stores energy. Conversely, if *the system does work on the surroundings*, as when a gas expands and pushes a piston, the system loses some energy by changing part of its potential energy to kinetic energy, which is transferred to the surroundings. The **first law of thermodynamics** expresses the net change in energy mathematically by the equation

■ ΔE = (heat input) + (work input)

$$\Delta E = q + w$$

In Chapter 7 you learned that a positive sign on an energy change indicates energy gained by the system, whereas a negative sign indicates energy lost by the system. Thus, when . . .

q is $(+)$	Heat is absorbed by the system.
q is $(-)$	Heat is released by the system.
w is $(+)$	Work is done on the system.
w is $(-)$	Work is done by the system.

In the lab you may observe the reaction beaker becoming cool if q has a positive sign and you may feel it warm when heat is released. Similarly, you might observe the system expanding, especially when a gas is evolved, when work has a negative sign.

In Chapter 7 you also learned that ΔE is the difference between two state functions, $E_{\text{final}} - E_{\text{initial}}$, which means that its value does not depend on how a change from one state to another is carried out. The values of q and w strongly depend on how the system changes, as we illustrated in Figure 7.8 on page 270, and are not state functions. Engineers often try to maximize the work obtained for a given change while minimizing the loss of energy in the form of heat. The ratio of $w/\Delta E$ is called the thermodynamic efficiency of a given process.

Figure 19.1 | **Expanding gases can do work.** In a steam engine, such as the one powering this locomotive, heat is absorbed by water to turn it into high temperature, high pressure steam (q is positive). The steam then expands, pushing pistons and causing the locomotive to move. In the expansion, the steam does work and w is negative. *(Richard A. CookeIII/Stone/Getty Images)*

Pressure–Volume Work

There are two kinds of work that chemical systems can do (or have done on them) that are of concern to us. One is electrical work, which is examined in Chapter 20 and will be discussed there. The other is work associated with the expansion or contraction of a system under the influence of an external pressure. An example is the work you perform on a gas when you compress it to fill a tire (Figure 19.2). Such "pressure–volume" or P–V work was discussed in Chapter 7, where it was shown that this kind of work is given by the equation

$$w = -P\,\Delta V$$

where P is the *external pressure* on the system.

If P–V work, similar to the work that powers the diesel engine in Figure 19.3, is the only kind of work involved in a chemical change, the equation for ΔE takes the form

$$\Delta E = q + (-P\,\Delta V) = q - P\,\Delta V$$

In Chapter 7, we also showed that when a reaction takes place in a container whose volume cannot change, the entire energy change must appear as heat. Therefore, ΔE is called the heat at constant volume (q_v)

$$\Delta E = q_v$$

Figure 19.2 | **Work being done on a gas.** When a gas is *compressed* by an external pressure, w is positive because work is done on the gas. Because V decreases when the gas is compressed, the negative sign assures that w will be positive for the compression of a gas. *(Lawrence Manning/Corbis Images)*

Figure 19.3 | **Diesel engines are highly efficient.** In the cylinders of a diesel engine, air becomes very hot when compressed to a small volume because the work energy of compression is converted into heat energy. The temperature is so high that the fuel ignites when injected into the cylinder. The small explosion that occurs pushes the pistons to power large trucks and heavy equipment such as this diesel locomotive. *(John Griffin/The Image Works)*

Practice Exercises

19.1 | Molecules of an ideal gas have no intermolecular attractions and, therefore, undergo no change in potential energy on expansion of the gas. If the expansion is also at a constant temperature, there is no change in the kinetic energy, so the **isothermal** (constant temperature) expansion of an ideal gas has $\Delta E = 0$. Suppose such a gas expands at constant temperature from a volume of 1.0 L to 12.0 L against a constant opposing pressure of 14.0 atm. In units of *L atm*, what are q and w for this change? (*Hints*: Is the system doing work, or is work done on the system? What must be the sum of q and w in this case?)

19.2 | If a gas is compressed under **adiabatic** conditions (allowing no transfer of heat to or from the surroundings) by application of an external pressure, the temperature of the gas increases. Why?

Enthalpy

Rarely do we carry out reactions in containers of fixed volume. Usually, reactions take place in containers open to the atmosphere where they are exposed to a constant pressure. To study heats of reactions under constant pressure conditions, the term enthalpy is used. Recall that the **enthalpy, *H*,** is defined by the equation

$$H = E + PV$$

In Section 7.5 we showed that at constant pressure, the **enthalpy change, Δ*H*,** is equal to q_p

$$\Delta H = q_p$$

where q_p is the **heat at constant pressure**.

The Difference between ΔE and ΔH

In Chapter 7 we noted that ΔE and ΔH are not equal. They differ by the pressure–volume work, $-P\,\Delta V$.

$$\Delta E - \Delta H = -P\,\Delta V$$

■ The ΔV values for reactions involving only solids and liquids are very tiny, so ΔE and ΔH for these reactions are nearly the same size.

The only time ΔE and ΔH differ by a significant amount is when gases are formed or consumed in a reaction, and even then they do not differ by much. To calculate ΔE from ΔH (or ΔH from ΔE), we must have a way of calculating the pressure–volume work.

If we assume the gases in the reaction behave as ideal gases, then we can use the ideal gas law, rearranged to solve for V:

$$V = \frac{nRT}{P}$$

A volume change can therefore be expressed as

$$\Delta V = \Delta\left(\frac{nRT}{P}\right)$$

If pressure and temperature are held constant, only n can vary. We show this as Δn and write

$$\Delta V = \Delta n\left(\frac{RT}{P}\right)$$

Thus, when the reaction occurs at constant pressure, the volume change is caused by a change in the number of moles of *gas*. Of course, in chemical reactions not all reactants and products need to be gases, so to be sure we compute Δn correctly, let's express the change in the number of moles of gas as Δn_{gas}. It's defined as

$$\Delta n_{\text{gas}} = (n_{\text{gas}})_{\text{products}} - (n_{\text{gas}})_{\text{reactants}}$$

The $P\Delta V$ product is therefore,

$$P\Delta V = P \cdot \Delta n_{\text{gas}}\left(\frac{RT}{P}\right) = \Delta n_{\text{gas}} RT$$

Substituting into the equation for ΔH gives

$$\Delta H = \Delta E + \Delta n_{\text{gas}} RT \qquad (19.1)$$

TOOLS

Converting between ΔE and ΔH

The following example illustrates how small the difference is between ΔE and ΔH.

Example 19.1
Conversion between ΔE and ΔH

The decomposition of calcium carbonate in limestone is used industrially to make lime, CaO, for manufacturing cement.

$$CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$$

The reaction is endothermic and has $\Delta H° = +571$ kJ. What is the value of $\Delta E°$ for this reaction, and what is the difference between $\Delta H°$ and $\Delta E°$?

Analysis: In the preceding section we were reminded that the difference between the internal energy and the enthalpy is $-P\Delta V$. When temperature and pressure are held constant, $-P\Delta V$ is equal to $-\Delta n_{\text{gas}} RT$. Finally, the system is at standard state, as indicated by the superscript °, so the temperature is 25 °C; the number of moles can be obtained from the coefficients in the balanced chemical equation.

Assembling the Tools: We need to use the balanced chemical equation given in the problem statement and Equation 19.1.

$$\Delta H = \Delta E + \Delta n_{\text{gas}} RT$$

We add the superscript ° to ΔH and ΔE, and that defines a temperature of 25 °C (standard temperature for measuring heats of reaction). It is also important to remember that in calculating Δn_{gas}, we count just the moles of gas. Also, because we wish to calculate the term nRT in units of kilojoules, we will use $R = 8.314$ J mol^{-1} K^{-1}, being sure to convert J to kJ at the appropriate time.

Solution: Solving for ΔE and applying the superscript ° gives

$$\Delta E° = \Delta H° - \Delta n_{\text{gas}} RT$$

To calculate Δn_{gas} our chemical equation shows that there is one mole of gas among the products and no moles of gas among the reactants, so

$$\Delta n_{\text{gas}} = 1 \text{ mol} - 0 \text{ mol} = 1 \text{ mol}$$

The temperature is 298 K, and $R = 8.314$ J mol^{-1} K^{-1}. Substituting,

$$\begin{aligned}\Delta E° &= +571 \text{ kJ} - (1 \text{ mol})(8.314 \text{ J mol}^{-1} \text{ K}^{-1})(298 \text{ K})\\ &= +571 \text{ kJ} - 2480 \text{ J}\end{aligned}$$

We cannot add units of kJ to units of J, so we convert 2480 J to 2.48 kJ

$$\begin{aligned}\Delta E° &= +571 \text{ kJ} - 2.48 \text{ kJ}\\ &= +569 \text{ kJ}\end{aligned}$$

The difference between $\Delta H°$ and $\Delta E°$ is $\Delta n_{\text{gas}} RT$, or 2.48 kJ.

Is the Answer Reasonable? The equation we used predicts that $\Delta E°$ should be smaller than $\Delta H°$ if there is an increase in the moles of gas. Our result agrees with that assessment. We found the difference to be relatively small, which also agrees with the text above. Finally, the energy needed to decompose $CaCO_3$ at constant volume ($\Delta E°$) should be less than the energy needed at constant pressure ($\Delta H°$), because the enthalpy includes additional energy to do the work of pushing back the atmosphere as the system expands.

Practice Exercises

19.3 | Calculate the difference, in kilojoules, between ΔE and ΔH for the following exothermic reaction at 45 °C. Which is more exothermic, ΔE or ΔH? (*Hint*: Note the temperature.)

$$2N_2O(g) + 3O_2(g) \longrightarrow 4NO_2(g)$$

19.4 | The reaction

$$CaO(s) + 2HCl(g) \longrightarrow CaCl_2(s) + H_2O(g)$$

has $\Delta H° = -217.1$ kJ. Calculate $\Delta E°$ for this reaction. What is the percentage difference between $\Delta E°$ and $\Delta H°$? (Use one significant figure for your percentage.)

When we examine the result of Example 19.1 we find that the difference between $\Delta E°$ and $\Delta H°$ is very small. In this case it works out to be approximately 0.5%.

19.2 | Spontaneous Change

Now that we've reviewed the way thermodynamics treats energy changes, we turn our attention to one of our main goals in studying this subject—finding relationships among the factors that determine whether or not a change in a system will occur spontaneously. By **spontaneous change** we mean one that occurs by itself, without continuous outside assistance. Examples are water flowing over a waterfall, the burning of natural gas on a stove, and the melting of ice cubes in a cold drink on a warm day. These are events that proceed on their own.

Some spontaneous changes occur very rapidly. An example is the detonation of a stick of dynamite, or the exposure of photographic film. Other spontaneous events, such as the rusting of iron or the erosion of stone, occur slowly, and many years may pass before a change is noticed. Still others occur at such an extremely slow rate under ordinary conditions that they appear not to be spontaneous at all. Gasoline–oxygen mixtures appear perfectly stable indefinitely at room temperature because under these conditions they react very slowly. However, if exposed to a spark, their rate of reaction increases tremendously and they react explosively.

Each day we also witness events that are obviously *not* spontaneous. We may pass by a pile of bricks in the morning and later in the day find that they have become a brick wall. We know from experience that the wall didn't get there by itself. A pile of bricks becoming a brick wall is *not* spontaneous; it requires the intervention of a bricklayer. Similarly, the decomposition of water into hydrogen and oxygen is not spontaneous. We see water all the time and we know that it's stable. Nevertheless, we can cause water to decompose by passing an electric current through it in a process called *electrolysis* (Figure 19.4).

$$2H_2O(l) \xrightarrow{\text{electrolysis}} 2H_2(g) + O_2(g)$$

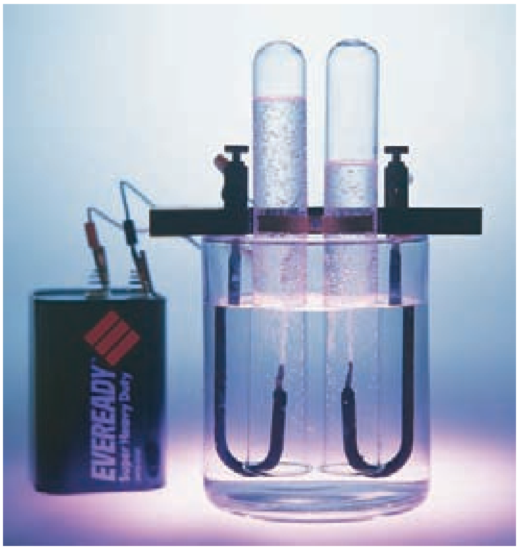

Figure 19.4 | **The electrolysis of water produces H_2 and O_2 gases.** It is a nonspontaneous change that only continues as long as electricity is supplied. *(Charles D. Winters/Photo Researchers)*

This decomposition will continue, however, only as long as the electric current is maintained. As soon as the supply of electricity is cut off, the decomposition ceases. This example demonstrates the difference between spontaneous and nonspontaneous changes. Once a spontaneous event begins, it has a tendency to continue until it is finished. A nonspontaneous event, on the other hand, can continue only as long as it receives some sort of outside assistance.

Nonspontaneous changes have another common characteristic. They are able to occur only when accompanied by some spontaneous change. For example, a bricklayer consumes food, and a series of spontaneous biochemical reactions then occur that supply the necessary muscle power to build the brick wall. Similarly, the nonspontaneous electrolysis of water requires some sort of spontaneous mechanical or chemical change to generate the needed electricity. In short, *all nonspontaneous events occur at the expense of spontaneous ones.* Everything that happens can be traced, either directly or indirectly, to spontaneous changes.

■ The driving of nonspontaneous reactions to completion by linking them to spontaneous ones is an important principle in biochemistry.

The reaction of gasoline vapor with oxygen, mentioned previously, illustrates an important observation about spontaneous changes. Even though the reaction between these substances has a strong tendency to occur, and is therefore spontaneous, the *rate of the reaction* at room temperature is so slow that the mixture appears to be stable. In other words, the reaction *appears* to be nonspontaneous because its rate is so slow. There are many reactions in nature that are spontaneous but occur at such a slow rate that they aren't observed. Biochemical reactions often fall into this category. Without the presence of a catalyst, an enzyme for instance, these reactions are so slow that effectively they do not occur. Living systems control their chemical reactions by selectively making enzymes available when spontaneous reactions or their products are needed.

Direction of Spontaneous Change

What determines the direction of spontaneous change? Let's begin by examining some everyday events such as those depicted in Figure 19.5. When iron rusts, heat is released, so the reaction lowers the internal energy of the system. Similarly, the chemical substances in the gasoline–oxygen mixture lose chemical energy by evolving heat as the gasoline burns to produce CO_2 and H_2O.

Since many spontaneous reactions are obviously exothermic, we might be tempted to conclude (as some nineteenth century chemists did) that spontaneous events occur because heat energy flows out of a system. This energy-lowering was labeled a "driving force" behind spontaneous change. In addition to the loss of heat energy in chemical reactions a change in potential energy can occur. For instance, when we drop a book, it spontaneously falls to the floor because that lowers its potential energy. Since a change that lowers the potential energy of a system is also exothermic, the old concept of spontaneity could be stated as: *Exothermic changes have a tendency to proceed spontaneously.*

■ Most, but not all, chemical reactions that are exothermic occur spontaneously.

Yet if this is so, how do we explain the third photograph in Figure 19.5? The melting of ice at room temperature is clearly a spontaneous process. But ice absorbs heat energy from the surroundings as it melts. This absorbed heat gives the water from the melted ice

Figure 19.5 | **Three common spontaneous events.** Iron rusts, fuel burns, and an ice cube melts at room temperature. *(left) George B. Diebold/Corbis Images; (center) Lowell J. Georgia/Photo Researchers; (right) Daniel Smith/Corbis)*

cube a higher internal energy than the original ice had. This is an example of a spontaneous but endothermic process. There are many other examples of spontaneous endothermic processes: the evaporation of acetone in nail polish remover, the expansion of carbon dioxide gas into a vacuum, the reaction of acetic acid with sodium carbonate, and the operation of a chemical "cold pack."

In Chapter 13 we discussed the solution process, and we said that one of the principal driving forces in the formation of a solution is the fact that the mixed state is much more probable than the unmixed state. It turns out that arguments like this can be used to explain the direction of any spontaneous process.

19.3 | Entropy

In Chapter 7 you learned that when a hot object is placed in contact with a colder one, heat will flow spontaneously from the hot object to the colder one. But why? The law of conservation of energy doesn't help, since energy is conserved no matter in which direction the heat flows.

To analyze what happens in the spontaneous flow of heat, let's imagine a situation in which we have two objects in contact with one another, one with a high temperature and the other with a low temperature. Because of the relationship between average kinetic energy and temperature, we expect the high-temperature object to have many rapidly moving molecules, whereas the low-temperature object will have more slow-speed molecules. Where the objects touch, many of the molecular collisions will involve fast-moving "hot" molecules and slow-moving "cold" ones. In such a collision, it is very unlikely that the fast molecule will gain kinetic energy at the expense of the slow one. Instead, the fast molecule will lose kinetic energy and slow down, while the slow molecule will gain kinetic energy and speed up. Over time, the result of many such collisions is that the hot object cools and the cool object warms. While this happens, the combined kinetic energy of the two objects becomes distributed over all the molecules in the system.

■ Imagine a game of billiards where a moving ball, the cue ball, hits a stationary ball. In the collision, we observe that the cue ball loses some, but not all, of its speed and the other ball is now in motion. The result is the transfer of energy from the "hot" cue ball to the "cold" stationary ball.

What we learn here is that heat flows because of the probable outcome of intermolecular collisions. Viewed on a larger scale, the uniform distribution of kinetic energy between the objects, caused by the flow of heat, is much more probable than a situation in which no heat flow occurs, which illustrates the role of probability in determining the direction of a spontaneous change. *Spontaneous processes tend to proceed from states of low probability to states of higher probability.* The higher probability states are those that allow more options for distributing energy among the molecules, so we can also say that *spontaneous processes tend to disperse energy.*

Distributing Energy in a System

■ The greater the statistical probability of a particular state, the greater is the entropy.

Because statistical probability is so important in determining the outcome of chemical and physical events, thermodynamics defines a state function, called **entropy** (symbol S), that is related to the possible number of equivalent ways that energy can be distributed in a system. The greater the number of ways to distribute energy, the larger is its statistical probability, and therefore the larger the value of the entropy (Figure 19.6). Figure 19.7 represents another way to visualize the spreading of energy, this time in the form of monetary units, into equivalent states.

Because entropy is a state function, a change in entropy, ΔS, is independent of the path taken between initial and final states. Therefore, we can write

$$\Delta S = S_{\text{final}} - S_{\text{initial}}$$

For a chemical reaction this becomes

$$\Delta S = S_{\text{products}} - S_{\text{reactants}}$$

Energy
High entropy (more ways to distribute energy)
Yellow dots represent energies of molecules of *B*.
(*b*)

Figure 19.6 | **A positive value for ΔS means an increase in the number of ways energy can be distributed among a system's molecules.** Consider the reaction $A \longrightarrow B$, where *A* can take on energies that are multiples of 10 energy units, and *B* can take on energies that are multiples of five units. Suppose that the total energy of the reacting mixture is 20 units. (*a*) There are two ways to distribute 20 units of energy among three molecules of *A*. (*b*) There are four ways to distribute 20 units of energy among three molecules of *B*. The entropy of *B* is higher than the entropy of *A* because there are more ways to distribute the same amount of energy in *B* than in *A*.

As you can see, when S_{final} is larger than S_{initial} (or when S_{products} is larger than $S_{\text{reactants}}$), the value of ΔS is positive. A positive value for ΔS means an increase in the number of energy-equivalent ways the system can be arranged, and we have seen that this kind of change tends to be spontaneous. This leads to a general statement about entropy:

> Any event that is accompanied by an increase in the entropy of the system will have a *tendency* to occur spontaneously.

Factors that Affect ΔS

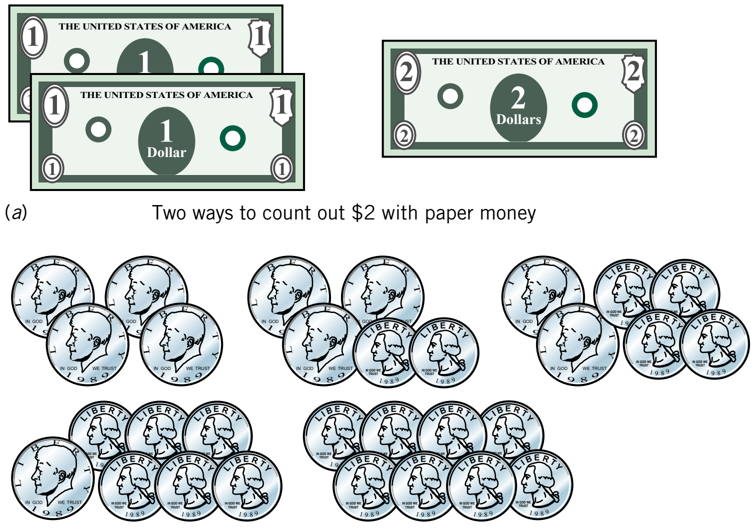
It is often possible to predict whether ΔS is positive or negative for a particular change. This is because several factors influence the magnitude of the entropy in predictable ways.

Volume

For gases, the entropy increases with increasing volume, as illustrated in Figure 19.8. At the left we see a gas confined to one side of a container, separated from a vacuum by a removable partition. Let's suppose the partition could be pulled away in an instant, as shown in Figure 19.8*b*. Now we find a situation in which all the molecules of the gas are at one end of a larger container. There are many more possible ways that the total kinetic energy can be distributed among the molecules in the larger volume. That makes the configuration in Figure 19.8*b* extremely unlikely. The gas expands spontaneously to achieve a more probable (higher entropy) particle distribution.

TOOLS

Factors affecting entropy: volume changes



(*a*) Two ways to count out \$2 with paper money

(*b*) Five ways to count out \$2 with 50¢ and 25¢ coins

Figure 19.7 | **Entropy.** If energy were money, entropy would describe the number of different ways of counting it out. For example, (*a*) there are only two ways of counting out \$2 using American paper money, but (*b*) there are five ways of counting out \$2 using 50 cent and 25 cent coins. One could consider a system using coins as having more entropy than a system using just paper money.

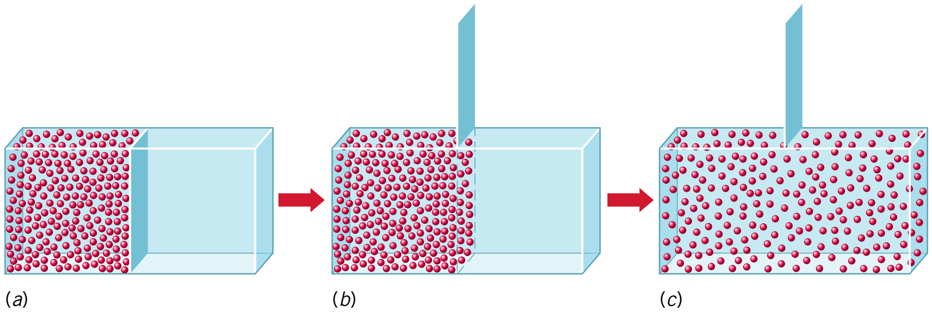


Figure 19.8 | **The expansion of a gas into a vacuum.** (*a*) A gas in a container separated from a vacuum by a partition. (*b*) The gas at the moment the partition is removed. (*c*) The gas expands to achieve a more probable (higher entropy) particle distribution.

Factors affecting entropy: temperature changes

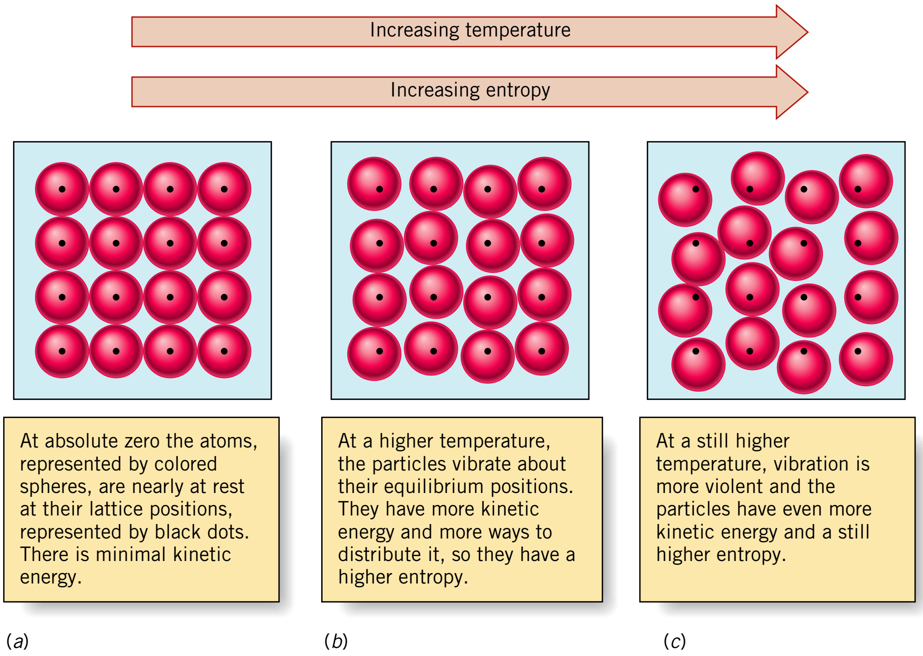
Temperature

The entropy is also affected by the temperature; the higher the temperature the larger is the entropy. For example, when a substance is a solid at absolute zero, its particles are essentially motionless. There is relatively little kinetic energy, and so there are few ways to distribute kinetic energy among the particles, so the entropy of the solid is relatively low (Figure 19.9*a*). If some heat is added to the solid, the kinetic energy of the particles increases along with the temperature. This causes the particles to move and vibrate within the crystal, so at a particular moment (pictured in Figure 19.9*b*) the particles are not found exactly at their lattice sites. There is more kinetic energy than at the lower temperature, and there are more ways to distribute it among the molecules, so the entropy is larger. If the temperature is raised further, the particles are given even more kinetic energy with an even larger number of possible ways to distribute it, causing the solid to have a still higher entropy (Figure 19.9*c*).

Factors affecting entropy: physical state

Physical State

One of the major factors that affects the entropy of a system is its physical state, which is demonstrated in Figure 19.10. Suppose that the diagrams represent ice, water, and water vapor all at the same temperature. There is greater freedom of molecular movement in water than in ice at the same temperature, and so there are more ways to distribute kinetic energy among the molecules of liquid water than there are in ice. The water molecules in the vapor are free to move through the entire container. They are able to distribute their kinetic energies in a very large number of ways. In general, therefore, there are many more



At absolute zero the atoms, represented by colored spheres, are nearly at rest at their lattice positions, represented by black dots. There is minimal kinetic energy.

At a higher temperature, the particles vibrate about their equilibrium positions. They have more kinetic energy and more ways to distribute it, so they have a higher entropy.

At a still higher temperature, vibration is more violent and the particles have even more kinetic energy and a still higher entropy.

Figure 19.9 | **Variation of entropy with temperature.** (*a*) At absolute zero the atoms, represented by colored circles, rest at their equilibrium lattice positions, represented by black dots. Entropy is relatively low. (*b*) At a higher temperature, the particles vibrate about their equilibrium positions and there are more different ways to distribute kinetic energy among the molecules. Entropy is higher than in (*a*). (*c*) At a still higher temperature, vibration is more violent and at any instant the particles are found in even more arrangements. Entropy is higher than in (*b*).

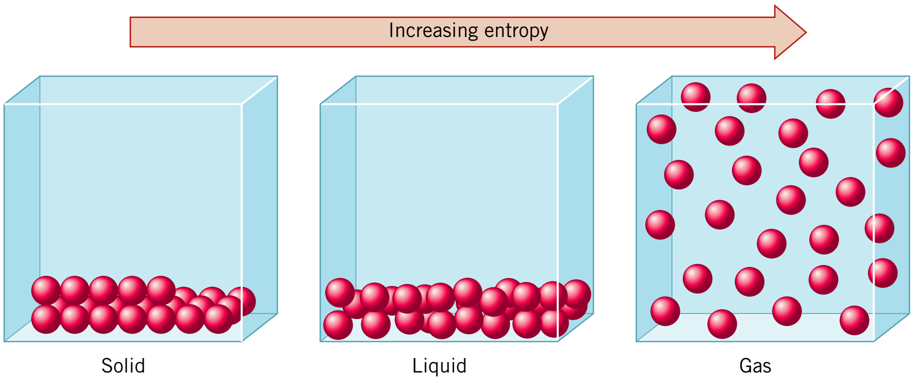


Figure 19.10 | **Comparison of the entropies of the solid, liquid, and gaseous states of a substance.** The crystalline solid has a very low entropy. The liquid has a higher entropy because its molecules can move more freely and there are more ways to distribute kinetic energy among them. All the particles are still found at one end of the container. The gas has the highest entropy because the particles are randomly distributed throughout the entire container, so there are many, many ways to distribute kinetic energy among the molecules.

possible ways to distribute kinetic energy among gas molecules than there are in liquids and solids. In fact, a gas has such a large entropy compared with a liquid or solid that changes which produce gases from liquids or solids are almost always accompanied by increases in entropy.

Number of Particles

Entropy, S, is an extensive property of a system just as H, the enthalpy, is an extensive property that depends on the amount of substance in the system. If we add more molecules to a system, there will be more ways to distribute the total energy of the system, and therefore the entropy is larger.

TOOLS

Factors affecting entropy: number of particles

Predicting the Sign of ΔS for a Chemical Reaction

When a chemical reaction produces or consumes gases, the sign of its entropy change is usually easy to predict. This is because the entropy of a gas is so much larger than that of either a liquid or solid. For example, the thermal decomposition of sodium bicarbonate produces two gases, CO_2 and H_2O.

$$2NaHCO_3(s) \xrightarrow{\text{heat}} Na_2CO_3(s) + CO_2(g) + H_2O(g)$$

Because the amount of gaseous products is larger than the amount of gaseous reactants, we can predict that the entropy change for the reaction is positive. On the other hand, the reaction

$$CaO(s) + SO_2(g) \longrightarrow CaSO_3(s)$$

(which can be used to remove sulfur dioxide from a gas mixture) has a negative entropy change because the number of gas molecules decreases as the reaction progresses.

For chemical reactions, another major factor that affects the sign of ΔS is a change in the total number of molecules as the reaction proceeds. When more molecules are produced during a reaction, more ways of distributing the energy among the molecules are possible. *When all other things are equal, reactions that increase the number of particles in the system tend to have a positive entropy change*, as shown in Figure 19.11.

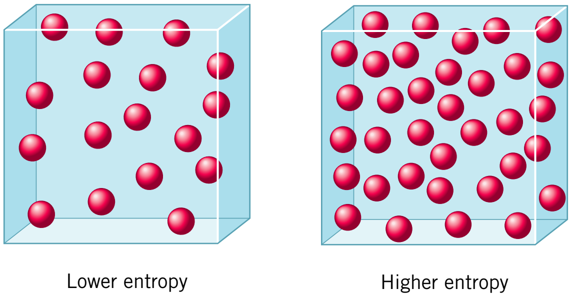

Figure 19.11 | **Entropy is affected by number of particles.** Adding additional particles to a system increases the number of ways that energy can be distributed in the system, so with all other things being equal, a reaction that produces more particles will have a positive value of ΔS.

Example 19.2
Predicting the Sign of ΔS

Predict the algebraic sign of ΔS for the reactions:

(a) $2NO_2(g) \longrightarrow N_2O_4(g)$

(b) $C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(g)$

■ **Analysis:** We will need to consider all of the factors that have an effect on the entropy change of the particular systems given to us. We note that all substances are in the gas phase, and no temperature change is specified. Therefore, phase change and temperature changes do not need to be considered.

■ **Assembling the Tools:** The tools we need are the factors that affect the entropy of a system when there are (1) changes in the number of gas molecules and (2) changes in the number of particles on going from reactants to products.

■ **Solution:** In reaction (a) we are forming fewer, more complex molecules (N_2O_4) from simpler ones (NO_2). Since we are forming fewer molecules, there are fewer ways to distribute energy among them, which means that the entropy must be decreasing. Therefore, ΔS must be negative. We reach the same conclusion by noting that one mole of gaseous product is formed from two moles of the gaseous reactant. When there is a decrease in the number of moles of gas, the reaction tends to have a negative ΔS.

For reaction (b), we can count the number of molecules on both sides. On the left of the equation we have six molecules; on the right there are seven. There are more ways to distribute kinetic energy among seven molecules than among six, so for reaction (b), we expect ΔS to be positive. We reach the same conclusion by counting the number of moles of gas on both sides of the equation. On the left there are 6 moles of gas; on the right there are 7 moles of gas. Because the number of moles of gas is increasing, we expect ΔS to be positive.

■ **Is the Answer Reasonable?** The only check we can perform here is to carefully review our reasoning. It appears sound, so the answers appear to be correct.

Practice Exercises

19.5 | Would you expect the ΔS to be positive or negative for the following:

$$Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$$

(*Hint*: How is the freedom of movement of the ions affected?)

19.6 | Predict the sign of the entropy change for (a) the condensation of steam to liquid water and (b) the sublimation of solid iodine.

19.7 | Predict the sign of ΔS for the following reactions:

(a) $2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$

(b) $CO(g) + 2H_2(g) \longrightarrow CH_3OH(g)$

19.8 | What is the expected sign of ΔS for the following reactions? Justify your answers.

(a) $2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$

(b) $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$

(c) $Ca(OH)_2(s) \xrightarrow{H_2O} Ca^{2+}(aq) + 2OH^-(aq)$

19.4 | Second Law of Thermodynamics

You have learned that enthalpy and entropy are two factors that affect the spontaneity of a physical or chemical event. Sometimes they work together to favor a change, as in the combustion of gasoline where heat is given off (an exothermic change) and large volumes of gases are formed (an entropy increase).

In many situations, the enthalpy and entropy changes oppose each other, as in the melting of ice. Melting absorbs heat and is endothermic, which tends to make the process nonspontaneous. However, the greater freedom of motion of the molecules that accompanies melting has the opposite effect and tends to make the change spontaneous.

When the enthalpy and entropy changes conflict, temperature becomes a critical factor that can influence the direction in which the change is spontaneous. For example, consider a mixture of solid ice and liquid water. If we attempt to raise the temperature of the mixture to 25 °C, all the solid will melt. At 25 °C the change *solid* ⟶ *liquid* is spontaneous. On the other hand, if we attempt to cool the mixture to −25 °C, freezing occurs, so at −25 °C the opposite change, *liquid* ⟶ *solid*, is spontaneous. *Thus, there are actually three factors that can influence spontaneity: the enthalpy change, the entropy change, and the temperature.* The balance between these factors comes into focus through the second law of thermodynamics.

■ Knowledge of ΔS, ΔH, and T will allow us to determine if a system will undergo a spontaneous change.

Second Law of Thermodynamics

One of the most far-reaching observations in science is incorporated into the **second law of thermodynamics**, which states, in effect, that *whenever a spontaneous event takes place in our universe, the total entropy of the universe increases* ($\Delta S_{\text{total}} > 0$). Notice that the increase in entropy that's referred to here is for the *total* entropy of the *universe* (system *plus* surroundings), not just the system alone. This means that a system's entropy can decrease, just as long as there is a larger increase in the entropy of the surroundings so that the *overall* entropy change is positive. Because everything that happens relies on spontaneous changes of some sort, the entropy of the universe is constantly rising.

Now let's examine more closely the entropy change for the universe. As we've suggested, this quantity equals the sum of the entropy change for the system plus the entropy change for the surroundings.

$$\Delta S_{\text{total}} = \Delta S_{\text{system}} + \Delta S_{\text{surroundings}}$$

It can be shown that the entropy change for the surroundings is equal to the heat transferred *to* the surroundings *from* the system, $q_{\text{surroundings}}$, divided by the Kelvin temperature, T, at which it is transferred.

$$\Delta S_{\text{surroundings}} = \frac{q_{\text{surroundings}}}{T}$$

The law of conservation of energy requires that the heat transferred to the surroundings equals the negative of the heat added to the system, so we can write

$$q_{\text{surroundings}} = -\, q_{\text{system}}$$

In our study of the first law of thermodynamics we saw that for changes at constant temperature and pressure, $q_{\text{system}} = \Delta H$ for the system. By substitutions, therefore, we arrive at the relationship

$$\Delta S_{\text{surroundings}} = \frac{-\Delta H_{\text{system}}}{T}$$

and the entropy change for the entire universe becomes

$$\Delta S_{\text{total}} = \Delta S_{\text{system}} - \frac{\Delta H_{\text{system}}}{T}$$

By rearranging the right side of this equation, we obtain

$$\Delta S_{\text{total}} = \frac{T\,\Delta S_{\text{system}} - \Delta H_{\text{system}}}{T}$$

Now let's multiply both sides of the equation by T to give

$$T\,\Delta S_{\text{total}} = T\,\Delta S_{\text{system}} - \Delta H_{\text{system}}$$

or

$$T\,\Delta S_{\text{total}} = -(\Delta H_{\text{system}} - T\,\Delta S_{\text{system}})$$

Because ΔS_{total} must be positive for a spontaneous change, the quantity in parentheses, $(\Delta H_{\text{system}} - T\,\Delta S_{\text{system}})$, must be negative. Therefore, we can state that for a change to be spontaneous,

$$\Delta H_{\text{system}} - T\,\Delta S_{\text{system}} < 0 \qquad \textbf{(19.2)}$$

The Gibbs Free Energy

Equation 19.2 gives us a way of examining the balance between ΔH, ΔS, and temperature in determining the spontaneity of an event, and it becomes convenient at this point to introduce another thermodynamic state function. It is called the **Gibbs free energy, *G*,** named to honor one of America's greatest scientists, Josiah Willard Gibbs (1839–1903). (It's called *free energy* because it is related, as we will see later, to the maximum energy in a change that is "free" or "available" to do useful work.) The Gibbs free energy is defined as

■ The origin of *free* in *free energy* is discussed in Section 19.7.

$$G = H - TS \qquad \textbf{(19.3)}$$

so for changes at constant T and P, this equation becomes

TOOLS

Gibbs free energy

$$\boxed{\Delta G = \Delta H - T\,\Delta S} \qquad \textbf{(19.4)}$$

Because G is defined entirely in terms of state functions, it is also a state function. This means that

$$\Delta G = G_{\text{final}} - G_{\text{initial}} \qquad \textbf{(19.5)}$$

By comparing Equations 19.2 and 19.4, we arrive at the special importance of the free energy change:

TOOLS

ΔG as a predictor of spontaneity

> At constant temperature and pressure, a change can only be spontaneous if it is accompanied by a decrease in the free energy of the system.

In other words, for a change to be spontaneous, G_{final} must be less than G_{initial} and ΔG must be negative. With this in mind, we can now examine how ΔH, ΔS, and T are related in determining spontaneity.

■ Reactions that occur with a free energy decrease are sometimes said to be **exergonic**. Those that occur with a free energy increase are sometimes said to be **endergonic**.

When ΔH Is Negative and ΔS Is Positive

The combustion of octane (a component of gasoline),

$$2C_8H_{18}(l) + 25O_2(g) \longrightarrow 16CO_2(g) + 18H_2O(g)$$

is a very exothermic reaction. There is also a large increase in entropy because the number of particles in the system increases and large volumes of gases are formed. For this change, ΔH is negative and ΔS is positive, both of which favor spontaneity. Let's analyze how this affects the sign of ΔG.

$$\begin{aligned}&\Delta H \text{ is negative } (-)\\ &\Delta S \text{ is positive } (+)\\ &\Delta G = \Delta H - T\,\Delta S\\ &\quad\;\; = (-) - [T(+)]\end{aligned}$$

Notice that regardless of the absolute temperature, which must be a positive number, ΔG will be negative. This means that regardless of the temperature, such a change must be spontaneous. In fact, once started, fires will continue to consume all available fuel or oxygen at nearly any temperature because combustion reactions are always spontaneous (see Figure 19.12*a*).

(*a*) (*b*) (*c*)

Figure 19.12 | **Process spontaneity can be predicted if ΔH, ΔS, and T are known.** (*a*) When ΔH is negative and ΔS is positive, as in any combustion reaction, the reaction is spontaneous at any temperature. (*b*) When ΔH is positive and ΔS is negative, the process is not spontaneous. Left to themselves, ash, carbon dioxide, and water will not spontaneously combine to form wood. (*c*) When ΔH and ΔS have the same sign, temperature determines whether the process is spontaneous or not. Water spontaneously becomes ice below 0 °C, and ice spontaneously melts into liquid water above 0 °C. *(a: Corbis Images; b: iStockphoto; c: John Berry/The Image Works)*

When ΔH Is Positive and ΔS Is Negative

When a change is endothermic and is accompanied by a lowering of the entropy, both factors work against spontaneity.

$$\begin{aligned}&\Delta H \text{ is positive } (+)\\&\Delta S \text{ is negative } (-)\\&\Delta G = \Delta H - T\Delta S\\&\quad\;\, = (+) - [T(-)]\end{aligned}$$

Now, no matter what the temperature is, ΔG will be positive and the change must be nonspontaneous. An example would be carbon dioxide and water coming back together to form wood and oxygen again in a fire (Figure 19.12*b*).[1] If you saw such a thing happen in a video, such as on YouTube, experience would tell you that the video was being played backwards.

When ΔH and ΔS Have the Same Sign

When ΔH and ΔS have the same algebraic sign, the temperature becomes the determining factor in controlling spontaneity. If ΔH and ΔS are both positive, then

$$\Delta G = (+) - [T(+)]$$

Thus, ΔG is the difference between two positive quantities, ΔH and $T\Delta S$. This difference will only be negative if the term $T\Delta S$ is larger in magnitude than ΔH, and this will only be true when the temperature is high. In other words, *when ΔH and ΔS are both positive, the change will be spontaneous at high temperature but not at low temperature.* A change noted above is the melting of ice.

$$H_2O(s) \longrightarrow H_2O(l)$$

---

[1] Plants can manufacture wood from carbon dioxide and water that they take in, but the reaction by itself is *not* spontaneous. Plant cells manufacture wood by coupling this nonspontaneous reaction to a complex series of reactions with negative values of ΔG, so that the entire chain of reactions *taken together* is spontaneous overall. This same trick is used to drive nonspontaneous processes forward in human cells. The high negative free energy change from the breakdown of sugar and other nutrients is coupled with the nonspontaneous synthesis of complex proteins from simple starting materials, driving cell growth and making life possible.

This is a change that is endothermic and also accompanied by an increase in entropy. We know that at high temperature (above 0 °C) melting is spontaneous, but at low temperature (below 0 °C) it is not.

For similar reasons, when ΔH and ΔS are both negative, ΔG will be negative (and the change spontaneous) only when the temperature is low.

$$\Delta G = (-) - [T(-)]$$

Only when the negative value of ΔH is larger in magnitude than the negative value of $T\,\Delta S$ will ΔG be negative. Such a change is only spontaneous at low temperature. An example is the freezing of water (see Figure 19.12*c*).

$$H_2O(l) \longrightarrow H_2O(s)$$

This is an exothermic change that is accompanied by an decrease in entropy; it is only spontaneous at low temperatures (i.e., below 0 °C).

Figure 19.13 summarizes the effects of the signs of ΔH and ΔS on ΔG, and hence on the spontaneity of physical and chemical events.

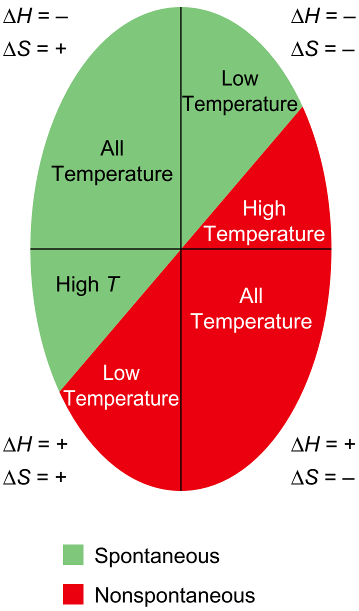

Figure 19.13 | **Summary of the effects of the signs of ΔH and ΔS on spontaneity as a function of temperature.** When ΔH and ΔS have the same sign, spontaneity is determined by the temperature.

19.5 | Third Law of Thermodynamics

Earlier we described how the entropy of a substance depends on temperature, and we noted that at absolute zero the order within a crystal is a maximum and the entropy is a minimum. The **third law of thermodynamics** goes one step farther by stating: *At absolute zero the entropy of a perfectly ordered pure crystalline substance is zero.*

$$S = 0 \quad \text{at} \quad T = 0\text{ K}$$

Because we know the point at which entropy has a value of zero, it is possible by *experimental measurement* and calculation to determine the total amount of entropy that a substance has at temperatures above 0 K.

If the entropy of one mole of a substance is determined at a temperature of 298 K (25 °C) and a pressure of 1 atm, we call it the **standard entropy, $S°$**. Table 19.1 lists the standard entropies for a number of substances.[2] Notice that entropy has the dimensions of energy/temperature (i.e., joules per kelvin); this is explained in *Chemistry Outside the Classroom 19.1.*

■ 25 °C and 1 atm are the same standard conditions we used in our discussion of $\Delta H°$ in Chapter 7.

Calculating $\Delta S°$ for a Reaction

Once we have the standard entropies of a variety of substances, we can calculate the **standard entropy change, $\Delta S°$**, for chemical reactions in much the same way as we calculated $\Delta H°$ in Chapter 7.

TOOLS

Standard entropy changes

$$\Delta S° = (\text{sum of } S° \text{ of the products}) - (\text{sum of } S° \text{ of the reactants}) \tag{19.6}$$

If the reaction we are working with happens to correspond to the formation of 1 mol of a compound from its elements, then the $\Delta S°$ that we calculate can be referred to as the **standard entropy of formation, $\Delta S_f°$**. Values of $\Delta S_f°$ are not tabulated, however; if we need them for some purpose, we must calculate them from tabulated values of $S°$.

■ This is simply a Hess's law type of calculation. Note, however, that elements have nonzero $S°$ values, which must be included in the bookkeeping.

---

[2] In our earlier discussions of standard states (Chapter 7) we defined the *standard pressure* as 1 atm. This was the original pressure unit used by thermodynamicists. However, in the SI, the recognized unit of pressure is the pascal (Pa), not the atmosphere. After considerable discussion, the SI adopted the **bar** as the standard pressure for thermodynamic quantities: 1 bar = 10^5 Pa. One bar differs from one atmosphere by only 1.3%, and for thermodynamic quantities that we deal with in this text, their values at 1 atm and at 1 bar differ by an insignificant amount. Since most available thermodynamic data is still specified at 1 atm rather than 1 bar, we shall continue to use 1 atm for the standard pressure.

Table 19.1 Standard Entropies of Some Typical Substances at 298.15 K

Substance	$S°$ (J mol^{-1} K^{-1})	Substance	$S°$ (J mol^{-1} K^{-1})	Substance	$S°$ (J mol^{-1} K^{-1})
$Ag(s)$	42.55	$CaO(s)$	40	$N_2(g)$	191.5
$AgCl(s)$	96.2	$Ca(OH)_2(s)$	76.1	$NH_3(g)$	192.5
$Al(s)$	28.3	$CaSO_4(s)$	107	$NH_4Cl(s)$	94.6
$Al_2O_3(s)$	51.0	$CaSO_4 \cdot \frac{1}{2}H_2O(s)$	131	$NO(g)$	210.6
$C(s)$ (graphite)	5.69	$CaSO_4 \cdot 2H_2O(s)$	194.0	$NO_2(g)$	240.5
$CO(g)$	197.9	$Cl_2(g)$	223.0	$N_2O(g)$	220.0
$CO_2(g)$	213.6	$Fe(s)$	27	$N_2O_4(g)$	304
$CH_4(g)$	186.2	$Fe_2O_3(s)$	90.0	$Na(s)$	51.0
$CH_3Cl(g)$	234.2	$H_2(g)$	130.6	$Na_2CO_3(s)$	136
$CH_3OH(l)$	126.8	$H_2O(g)$	188.7	$NaHCO_3(s)$	102
$CO(NH_2)_2(s)$	104.6	$H_2O(l)$	69.96	$NaCl(s)$	72.38
$CO(NH_2)_2(aq)$	173.8	$HCl(g)$	186.7	$NaOH(s)$	64.18
$C_2H_2(g)$	200.8	$HNO_3(l)$	155.6	$Na_2SO_4(s)$	149.4
$C_2H_4(g)$	219.8	$H_2SO_4(l)$	157	$O_2(g)$	205.0
$C_2H_6(g)$	229.5	$HC_2H_3O_2(l)$	160	$PbO(s)$	67.8
$C_8H_{18}(l)$	466.9	$Hg(l)$	76.1	$S(s)$	31.9
$C_2H_5OH(l)$	161	$Hg(g)$	175	$SO_2(g)$	248.5
$Ca(s)$	41.4	$K(s)$	64.18	$SO_3(g)$	256.2
$CaCO_3(s)$	92.9	$KCl(s)$	82.59		
$CaCl_2(s)$	114	$K_2SO_4(s)$	176		

Example 19.3
Calculating $\Delta S°$ from Standard Entropies

Urea (a compound found in urine) is manufactured commercially from CO_2 and NH_3. One of its uses is as a fertilizer, where it reacts slowly with water in the soil to produce ammonia and carbon dioxide. The ammonia provides a source of nitrogen for growing plants.

$$\underset{\text{urea}}{CO(NH_2)_2(aq)} + H_2O(l) \longrightarrow CO_2(g) + 2NH_3(g)$$

What is the standard entropy change when one mole of urea reacts with water?

■ **Analysis:** We need to combine standard entropies in the correct way to represent what occurs in the chemical reaction. We will use the principles just presented in this section. We can notice the similarity to the methods we learned for the determination of standard heats of reaction in Chapter 7.

■ **Assembling the Tools:** We need to use Equation 19.6 to compute the standard entropy change for the reaction. To do this we need the balanced chemical equation, above, and the data found in Table 19.1 that is listed in the table below.

Substance	$S°$ (J mol^{-1} K^{-1})
$CO(NH_2)_2(aq)$	173.8
$H_2O(l)$	69.96
$CO_2(g)$	213.6
$NH_3(g)$	192.5

CHEMISTRY OUTSIDE THE CLASSROOM 19.1

Carved in Stone

In 1870 Ludwig von Boltzmann (Figure 1) started developing the ideas and concepts that led to the modern field of science called statistical mechanics. Statistical mechanics describes the properties of large groups of particles based on the laws of probability and how the particles interact.

Figure 1 Ludwig von Boltzmann (February 20, 1844 to September 5, 1906) *(Hulton Archive /Getty Images, Inc.)*

In developing this field, Boltzmann developed his famous equation for entropy,

$$S = k \ln W$$

which is indeed carved in stone at his gravesite in Vienna, Austria (Figure 2). The equation states that the entropy of a particle is equal to the Boltzmann constant, $k = 1.38 \times 10^{-23}$ J mol^{-1} K^{-1}, times the natural logarithm of W, the number of different microstates that the particle can visit. The combination of the properties of all the microstates defines the macrostate, or state, of the system, which we observe on the basis of pressure, volume, temperature, and number of particles. Describing and counting microstates is beyond the scope of our discussion. However, two interesting results of Boltzmann's equation can be described easily.

First, let's consider a simple system, a perfect crystal of one of the elements. In such a crystal, there is only one arrangement of the atoms, often face-centered or body-centered cubic as shown in Chapter 12. Now let's lower the temperature to absolute zero. Since the temperature is directly proportional to the kinetic energy, this suggests that the kinetic energy, or movement, of the atoms is zero. (Quantum mechanics tells us this is not quite true.) However, the result is that a perfect crystal at 0 K has only one possible microstate, a totally ordered arrangement of all the atoms. Solving the Boltzmann equation when $W = 1$ tells us the entropy must be zero for a perfect crystal at absolute zero. This is the third law of thermodynamics.

S = k log W
LUDWIG
BOLTZMANN

Figure 2 A photo of the gravesite of Boltzmann with his equation engraved above his bust. *(Frantisek Zboray)*

A second case of interest involves entropy change. If we consider an ideal gas in a container, it will have some number of microstates, W_{initial}, that define its pressure, volume, temperature, and number of gas molecules. After the change we will have a new number of microstates, W_{final}. We can now write an equation for entropy change as

$$\begin{aligned}\Delta S &= k \ln W_{\text{final}} - k \ln W_{\text{initial}} \\ &= k \ln (W_{\text{final}} / W_{\text{initial}})\end{aligned}$$

For an ideal gas, the microstates are defined on the basis of the position and momentum of the particles. If we expand the gas isothermally, the temperature, and therefore momentum, mv, of the particles does not change. However, the number of positions that a particle can visit will change in direct proportion to the volume change. For example, if we take one mole of an ideal gas and triple its volume the entropy change will be

$$\begin{aligned}\Delta S &= (1.38 \times 10^{-23} \text{ J molecule}^{-1} \text{ K}^{-1}) \times \ln (3) \\ &= 1.52 \times 10^{-23} \text{ J molecule}^{-1} \text{ K}^{-1}\end{aligned}$$

For a mole of substance we multiply by Avogadro's number

$$\Delta S = \left(\frac{1.52 \times 10^{-23} \text{ J}}{\text{molecule K}}\right)\left(\frac{6.02 \times 10^{-23} \text{ molecules}}{\text{mole}}\right)$$

$$\Delta S = 9.13 \text{ J mol}^{-1} \text{ K}^{-1}$$

Since we expanded one mole of gas, the entropy change is 9.13 J K^{-1}.

Solution: Applying Equation 19.6, we have

$$\begin{aligned}
\Delta S^\circ &= \left[S^\circ_{CO_2(g)} + 2S^\circ_{NH_3(g)}\right] - \left[S^\circ_{CO(NH_2)_2(aq)} + S^\circ_{H_2O(l)}\right] \\
&= \left[1\ \cancel{\text{mol}} \times \left(\frac{213.6\ \text{J}}{\cancel{\text{mol}}\ \text{K}}\right) + 2\ \cancel{\text{mol}} \times \left(\frac{192.5\ \text{J}}{\cancel{\text{mol}}\ \text{K}}\right)\right] \\
&\quad - \left[1\ \cancel{\text{mol}} \times \left(\frac{173.8\ \text{J}}{\cancel{\text{mol}}\ \text{K}}\right) + 1\ \cancel{\text{mol}} \times \left(\frac{69.96\ \text{J}}{\cancel{\text{mol}}\ \text{K}}\right)\right] \\
&= (598.6\ \text{J/K}) - (243.8\ \text{J/K}) \\
&= 354.8\ \text{J/K}
\end{aligned}$$

Notice that the unit *mol* cancels in each term, so the units of ΔS° are joules per kelvin.

Thus, the standard entropy change for this reaction is $+354.8$ J/K (which we can also write as $+354.8\ \text{J K}^{-1}$).

Is the Answer Reasonable? In the reaction, gases are formed from liquid reactants. Since gases have much larger entropies than liquids, we expect ΔS° to be positive, which agrees with our answer.

Practice Exercises

19.9 | Calculate ΔS°_f for $NH_3(g)$. (*Hint*: Write the equation for the reaction; see Section 7.8.)

19.10 | Calculate the standard entropy change, ΔS°, in J K^{-1} for the following reactions:

(a) $CaO(s) + 2HCl(g) \longrightarrow CaCl_2(s) + H_2O(l)$

(b) $C_2H_4(g) + H_2(g) \longrightarrow C_2H_6(g)$

19.6 | Standard Free Energy Change, ΔG°

When ΔG is determined at 25 °C (298 K) and 1 atm, we call it the **standard free energy change,**[3] **ΔG°.** There are several ways of obtaining ΔG° for a reaction. One of them is to compute ΔG° from ΔH° and ΔS° using an expression analogous to Equation 19.4.

$$\Delta G^\circ = \Delta H^\circ - (298.15\ \text{K})\,\Delta S^\circ$$

TOOLS

Calculating ΔG° from ΔH° and ΔS°

Experimental measurement of ΔG° is also possible, but we will discuss how this is done later.

Example 19.4
Calculating ΔG° from ΔH° and ΔS°

Calculate ΔG° for the reaction of urea with water from values of ΔH° and ΔS°.

$$CO(NH_2)_2(aq) + H_2O(l) \longrightarrow CO_2(g) + 2NH_3(g)$$

Analysis: This problem has two parts. From Chapter 7 we found out how to calculate the standard heat of reaction, ΔH°, and in this chapter we found out how to determine ΔS°. Once we have ΔH° and ΔS°, we need to combine them in the correct way to obtain ΔG°.

---

[3] Sometimes, the temperature is specified as a subscript in writing the symbol for the standard free energy change. For example, ΔG° can also be written ΔG°_{298}. As you will see later, there are times when it is desirable to indicate the temperature explicitly.

Assembling the Tools: We can calculate $\Delta G°$ with the equation

$$\Delta G° = \Delta H° - 298.15\text{ K}\,\Delta S°$$

Before calculating any values we need the balanced chemical equation, which is given in the statement of the problem. To calculate $\Delta H°$, we can use Hess's law as a tool with the data in Table 7.2. To obtain $\Delta S°$, we normally would need to do a similar calculation using Equation 19.6 as a tool with data from Table 19.1. However, we already performed this calculation in Example 19.3.

Solution: First we calculate $\Delta H°$ from data in Table 7.2.

$$\begin{aligned}\Delta H° &= \left[\Delta H°_{\text{f CO}_2(g)} + 2\Delta H°_{\text{f NH}_3(g)}\right] - \left[\Delta H°_{\text{f CO(NH}_2)_2(aq)} + \Delta H°_{\text{f H}_2\text{O}(l)}\right]\\ &= \left[1\ \cancel{\text{mol}} \times \left(\frac{-393.5\text{ kJ}}{\cancel{\text{mol}}}\right) + 2\ \cancel{\text{mol}} \times \left(\frac{-46.19\text{ kJ}}{\cancel{\text{mol}}}\right)\right]\\ &\quad - \left[1\ \cancel{\text{mol}} \times \left(\frac{-319.2\text{ kJ}}{\cancel{\text{mol}}}\right) + 1\ \cancel{\text{mol}} \times \left(\frac{-285.9\text{ kJ}}{\cancel{\text{mol}}}\right)\right]\\ &= (-485.9\text{ kJ}) - (-605.1\text{ kJ})\\ &= +119.2\text{ kJ}\end{aligned}$$

In Example 19.3 we found $\Delta S°$ to be $+354.8\text{ J K}^{-1}$. To calculate $\Delta G°$ we also need the Kelvin temperature, which we must express to at least four significant figures to match the number of significant figures in $\Delta S°$. Since standard temperature is *exactly* 25 °C, $T_K = (25.00 + 273.15)\text{ K} = 298.15\text{ K}$. Also, we must be careful to express the energy units of $\Delta H°$ and $T\Delta S°$ with the same SI prefix so they combine correctly. We'll change $\Delta S°$ from $+354.8\text{ J K}^{-1}$ to $+0.3548\text{ kJ K}^{-1}$. Substituting into the equation for $\Delta G°$,

$354.8\text{ J K}^{-1} = 0.3548\text{ kJ K}^{-1}$

$$\begin{aligned}\Delta G° &= +119.2\text{ kJ} - (298.15\,\cancel{\text{K}})(0.3548\text{ kJ}\,\cancel{\text{K}^{-1}})\\ &= +119.2\text{ kJ} - 105.8\text{ kJ}\\ &= +13.4\text{ kJ}\end{aligned}$$

Therefore, for this reaction, $\Delta G° = +13.4$ kJ.

Is the Answer Reasonable? There's not much we can do to check the reasonableness of the answer. We just need to check to be sure we've done the calculations correctly.

Practice Exercises

19.11 | Calculate $\Delta G°$ for the formation of one mole of N_2O_4 from its elements using $\Delta H°_f$ and $\Delta S°_f$ for N_2O_4. (*Hint*: Write the chemical equation.)

19.12 | Use the data in Table 7.2 and Table 19.1 to calculate $\Delta G°$ for the formation of iron(III) oxide (the iron oxide in rust). The equation for the reaction is

$$4\text{Fe}(s) + 3\text{O}_2(g) \longrightarrow 2\text{Fe}_2\text{O}_3(s)$$

In Section 7.8 you learned that it is useful to have tabulated standard heats of formation, $\Delta H°_f$, because they can be used with Hess's law to calculate $\Delta H°$ for many different reactions. **Standard free energies of formation, $\Delta G°_f$,** can be used in similar calculations to obtain $\Delta G°$ for a reaction or physical change.

Calculating $\Delta G°$ using $\Delta G°_f$ values

$$\Delta G° = (\text{sum of }\Delta G°_f\text{ of products}) - (\text{sum of }\Delta G°_f\text{ of reactants}) \tag{19.7}$$

The $\Delta G°_f$ values for some typical substances are listed in Table 19.2. Example 19.5 shows how we can use them to calculate $\Delta G°$ for a reaction.

Table 19.2 Standard Free Energies of Formation of Typical Substances at 298.15 K

Example 19.5
Calculating $\Delta G°$ from ΔG_f°

Ethanol, $\mathrm{C_2H_5OH}$, is made from grain by fermentation and is used as an additive to gasoline to produce a fuel mix called E85 (85% ethanol, 15% gasoline). What is $\Delta G°$ for the combustion of liquid ethanol to give $\mathrm{CO_2}(g)$ and $\mathrm{H_2O}(g)$?

E85
85% Ethanol
(© AP/Wide World Photos)

Analysis: The process for determining $\Delta G°$ is the same as we used for determining $\Delta H°$ and $\Delta S°$. Before we do anything, the balanced chemical equation will be needed.

Assembling the Tools: Our tool is Equation 19.7.

$$\Delta G° = (\text{sum of } \Delta G_f^\circ \text{ of products}) - (\text{sum of } \Delta G_f^\circ \text{ of reactants})$$

To use it we will need the balanced chemical equation for the reaction and ΔG_f° for each reactant and product. The free energy data are available in Table 19.2.

Solution: First, we write the balanced equation for the reaction.

$$\mathrm{C_2H_5OH}(l) + 3\mathrm{O_2}(g) \longrightarrow 2\mathrm{CO_2}(g) + 3\mathrm{H_2O}(g)$$

Applying Equation 19.7, we have

$$\Delta G^\circ = [2\Delta G^\circ_{\mathrm{f}\ \mathrm{CO_2}(g)} + 3\Delta G^\circ_{\mathrm{f}\ \mathrm{H_2O}(g)}] - [\Delta G^\circ_{\mathrm{f}\ \mathrm{C_2H_5OH}(l)} + 3\Delta G^\circ_{\mathrm{f}\ \mathrm{O_2}(g)}]$$

As with $\Delta H^\circ_\mathrm{f}$, the $\Delta G^\circ_\mathrm{f}$ for any element in its standard state is zero. Therefore, using the data from Table 19.2,

$$\begin{aligned}\Delta G^\circ &= \left[2\ \cancel{\text{mol}} \times \left(\frac{-394.4\ \text{kJ}}{\cancel{\text{mol}}}\right) + 3\ \cancel{\text{mol}} \times \left(\frac{-228.6\ \text{kJ}}{\cancel{\text{mol}}}\right)\right] - \left[1\ \cancel{\text{mol}} \times \left(\frac{-174.8\ \text{kJ}}{\cancel{\text{mol}}}\right) + 3\ \cancel{\text{mol}} \times \left(\frac{0\ \text{kJ}}{\cancel{\text{mol}}}\right)\right] \\ &= (-1474.6\ \text{kJ}) - (-174.8\ \text{kJ}) \\ &= -1299.8\ \text{kJ}\end{aligned}$$

The standard free energy change for the reaction equals −1299.8 kJ.

■ **Is the Answer Reasonable?** This is a combustion reaction for a compound containing only C, H and O. Very often, such combustion reactions are spontaneous with negative values for ΔG°. Our answer is obviously in the right ballpark.

Practice Exercises

19.13 | Calculate ΔG° for the reaction of iron(III) oxide with carbon monoxide to give elemental iron and carbon dioxide. (*Hint*: Be careful writing the balanced chemical equation.)

19.14 | Calculate $\Delta G^\circ_{\text{reaction}}$ in kilojoules for the following reactions using the data in Table 19.2.

(a) $2\mathrm{NO}(g) + \mathrm{O_2}(g) \longrightarrow 2\mathrm{NO_2}(g)$

(b) $\mathrm{Ca(OH)_2}(s) + 2\mathrm{HCl}(g) \longrightarrow \mathrm{CaCl_2}(s) + 2\mathrm{H_2O}(g)$

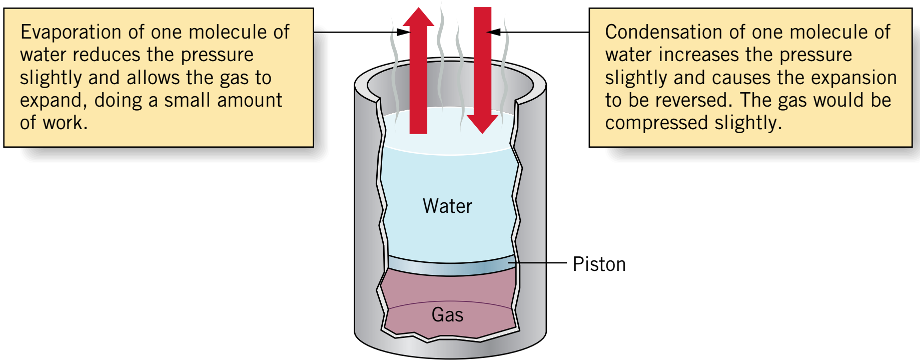
19.7 | Maximum Work and ΔG

One of the chief uses of spontaneous chemical reactions is the production of useful work. For example, fuels are burned in gasoline or diesel engines to power automobiles and heavy machinery, and chemical reactions in batteries start our autos and run all sorts of modern electronic gadgets, including cell phones, iPods, and laptop computers.

■ Gas and diesel engines are not very efficient, so most of the energy produced in the combustion of fuel appears as heat, not work. That's why these engines require cooling systems.

When chemical reactions occur, however, their energy is not always harnessed to do work. For instance, if gasoline is burned in an open dish, the energy evolved is lost entirely as heat and no useful work is accomplished. Engineers, therefore, seek ways to capture as much energy as possible in the form of work. One of their primary goals is to maximize the efficiency with which chemical energy is converted to work and to minimize the amount of energy transferred unproductively to the environment as heat.

Scientists have discovered that the maximum conversion of chemical energy to work occurs if a reaction is carried out under conditions that are said to be thermodynamically reversible. A process is defined as **thermodynamically reversible** if its driving force is opposed by another force that is just the slightest bit weaker, so that the slightest increase in the opposing force will cause the direction of the change to be reversed. An example of a nearly reversible process is illustrated in Figure 19.14, where we have a compressed gas in a cylinder pushing against a piston that's held in place by liquid water above it. If a water molecule evaporates, the external pressure drops slightly and the gas can expand just a bit, performing a small amount of work. Gradually, as one water molecule after another evaporates, the gas inside the cylinder slowly expands and performs work on the



Evaporation of one molecule of water reduces the pressure slightly and allows the gas to expand, doing a small amount of work.

Condensation of one molecule of water increases the pressure slightly and causes the expansion to be reversed. The gas would be compressed slightly.

Figure 19.14 | **A reversible expansion of a gas.** As water molecules evaporate one at a time, the external pressure gradually decreases and the gas slowly expands, performing a small amount of work in each step. The process would be reversed if a molecule of water were to condense into the liquid. The ability of the expansion to be reversed by the slightest increase in the opposing pressure is what makes this a reversible process.

surroundings. At any time, however, the process can be reversed by the condensation of a water molecule.[4]

Although we could obtain the maximum work by carrying out a change reversibly, a thermodynamically reversible process requires so many steps that it proceeds at an extremely slow speed. If the work cannot be done at a reasonable rate, it is of little value to us. Our goal, then, is to approach thermodynamic reversibility for maximum efficiency, but to carry out the change at a pace that will deliver work at acceptable rates.

The relationship of useful work to thermodynamic reversibility was illustrated earlier (Section 7.5) in our discussion of the discharge of an automobile battery. Recall that when the battery is shorted with a heavy wrench, no work is done and all the energy appears as heat. In this case there is nothing opposing the discharge, and it occurs in the most thermodynamically irreversible manner possible. However, when the current is passed through a small electric motor, the motor itself offers resistance to the passage of the electricity and the discharge takes place slowly. In this instance, the discharge occurs in a more nearly thermodynamically reversible manner because of the opposition provided by the motor, and a relatively large amount of the available energy appears in the form of the work accomplished by the motor.

The preceding discussion leads naturally to the question: Is there a limit to the amount of the available energy in a reaction that can be harnessed as useful work? The answer to this question is to be found in the Gibbs free energy.

> The maximum amount of energy produced by a reaction that can be *theoretically* harnessed as work is equal to ΔG.

This is the energy that need not be lost to the surroundings as heat and is therefore *free* to be used for work. Thus, by determining the value of ΔG, we can find out whether or not a given reaction will be an effective source of useful energy. Also, by comparing the actual amount of work derived from a given system with the ΔG values for the reactions involved, we can measure the efficiency of the system.

---

[4] Although we sometimes say that a chemical reaction is "reversible" because it can run in both the forward and reverse directions, we cannot say the reaction is *thermodynamically reversible* unless the concentrations are only infinitesimally different from their equilibrium values as the reaction occurs.

ON THE CUTTING EDGE | **19.2**

Thermodynamic Efficiency and Sustainability

The concept of sustainability incorporates the idea that the human race must consider the cumulative effects of our everyday activities and reinvent these activities so that we will not drive ourselves into extinction. It has been stated that 99.9% of all species that ever lived are now extinct. Humans have the possibility, because of our ability to think and plan, to avoid this fate. Chemists, physicists, and biologists will be very important in developing the tools that will make this effort successful.

Table 1 Efficiencies of Various Devices

Tungsten lightbulb	2–3%
Candle	0.04%
Gas mantle	0.2%
Light-emitting diode	Up to 22%
Fluorescent tube	Up to 15%
Compact fluorescent	Up to 12%
Electric motors	75 to 90%

Thermodynamics enters this discussion because it sets limits on our ability to use resources. For instance, the first law of thermodynamics suggests that a change in internal energy is the sum of the work and heat changes in the system. If work is the useful part of an energy change and heat is wasted energy, we can say that $w/(q + w)$ is the efficiency of the system. There are other measures of efficiency. For example Nicolas Léonard Sadi Carnot suggested that the efficiency of a heat engine is $(T_{\text{high}} - T_{\text{low}})/T_{\text{high}}$, where the high temperature exists inside the engine and the low temperature is the temperature of the exhaust. The best Carnot efficiency is realized in engines that have the greatest possible difference between the operating temperature and the waste heat temperature. Table 2 lists the efficiencies of some heat engines.

Engineers and research scientists realize that one part of realizing a sustainable energy economy is to maximize efficiency.

Figure 1 Combustion produces energy with a low efficiency and increased amounts of pollutants. *(© AP/Wide World Photos)*

Figure 2 Wind turbines convert wind energy to electricity with little on-site pollution. *(Henry Georgi/Aurora Photos Inc.)*

Table 2 Approximate Heat Engine Efficiencies

Gasoline engines	25–30%
Steam engines	8%
Diesel engines	40%
Steam turbines	60%

Modern sustainability calculations of efficiency include, along with the thermodynamic efficiency, the costs of all components of the process. For an electric generating facility, it includes the cost of the land that the facility uses, the cost of constructing the facility, the cost of waste disposal, and the cost of environmental impacts such as CO_2, NO_x, SO_2, and heat emissions to the environment. Employee, management, and regulatory costs are also included. The difficulty in sustainability calculations is finding an appropriate method for adding all these factors into a final, meaningful value.

With the modern realization of the many factors that comprise a simple activity such as the generation of electricity, there are many opportunities for chemists and other scientists to make significant contributions. Advanced lubricants can help increase the efficiency of many mechanical devices. Chemists and materials scientists design and fabricate materials that can withstand extremely high temperatures for long periods of time. Durable materials increase efficiency by reducing the "down-time" for frequent repairs. Although tungsten has a melting point of 3683 K it is not used in electric turbines because it is too brittle. However, tungsten nitride and silicon nitride are used successfully as very durable coatings in high-temperature generators. These same materials are used in the turbines of modern jet engines in commercial aircraft. (Figure 3.)

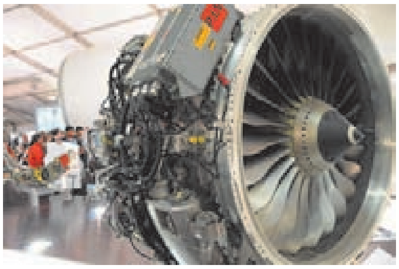


Figure 3 Cutaway of a jet engine showing high-speed, high-temperature turbine blades. *(Nick Lewis Photography/Alamy)*

Example 19.6

Calculating Maximum Work

Calculate the maximum work available, expressed in kilojoules, from the oxidation of 1 mol of octane, $C_8H_{18}(l)$, by oxygen to give $CO_2(g)$ and $H_2O(l)$ at 25 °C and 1 atm.

Analysis: The maximum work is equal to ΔG for the reaction. Standard thermodynamic conditions are specified, so we need to determine $\Delta G°$.

Assembling the Tools: The tool for this calculation is Equation 19.7.

$$\Delta G° = (\text{sum of } \Delta G_f° \text{ of products}) - (\text{sum of } \Delta G_f° \text{ of reactants})$$

Solution: First, we need a balanced equation for the reaction. For the complete oxidation (combustion) of one mole of C_8H_{18} we have

$$C_8H_{18}(l) + 12\tfrac{1}{2}O_2(g) \longrightarrow 8CO_2(g) + 9H_2O(l)$$

Then we apply Equation 19.7:

$$\Delta G° = [8\Delta G°_{f\,CO_2(g)} + 9\Delta G°_{f\,H_2O(l)}] - [\Delta G°_{f\,C_8H_{18}(l)} + 12.5\Delta G°_{f\,O_2(g)}]$$

Referring to Table 19.2 and dropping the canceled mol units,

$$\begin{aligned}\Delta G° &= [8 \times (-394.4)\text{ kJ} + 9 \times (-237.2)\text{ kJ}] - [1 \times (+17.3)\text{ kJ} + 12.5 \times (0)\text{ kJ}]\\ &= (-5290\text{ kJ}) - (+17.3\text{ kJ})\\ &= -5307\text{ kJ}\end{aligned}$$

Thus, at 25 °C and 1 atm, we can expect no more than 5307 kJ of work from the oxidation of 1 mol of C_8H_{18}.

Is the Answer Reasonable? Be sure to check the algebraic signs of each of the terms in the calculation. Also check that the stoichiometric coefficients multiply the correct $\Delta G°$ values. Finally, be sure that the correct $\Delta G°$ value for the liquid state of water is used. Since the table lists $\Delta G°$ values for two states of water, liquid and gas, this is a common source of error.

Figure 19.15 | **Blastoff of the space shuttle.** The large negative heat of formation of Al_2O_3 provides power to the solid-state booster rockets that lift the space shuttle from its launch pad. *(NASA)*

Practice Exercises

19.15 | Calculate the maximum work that could be obtained from the combustion of 125 g of ethanol, $C_2H_5OH(l)$. How does it compare with the maximum work from the combustion of 125 g of $C_8H_{18}(l)$? Which is the better fuel? (*Hint*: The work available *per mole* has already been calculated in the worked examples.)

19.16 | Calculate the maximum work that could be obtained at 25 °C and 1 atm from the oxidation of 1.00 mol of aluminum by $O_2(g)$ to give $Al_2O_3(s)$. (The combustion of aluminum in booster rockets provides part of the energy that lifts the space shuttle off its launching pad, Figure 19.15.)

19.8 | Free Energy and Equilibrium

We have seen that when the value of ΔG for a given change is negative, the change occurs spontaneously. We have also seen that a change is nonspontaneous when ΔG is positive. However, when ΔG is neither positive nor negative, the change is neither spontaneous nor nonspontaneous—the system is in a state of equilibrium. This occurs when ΔG is equal to zero.

When a system is in a state of dynamic equilibrium,

$$G_{\text{products}} = G_{\text{reactants}} \quad \text{and} \quad \Delta G = 0$$

Let's again consider the freezing of water:

$$H_2O(l) \rightleftharpoons H_2O(s)$$

Below 0 °C, ΔG for this change is negative and the freezing is spontaneous. On the other hand, above 0 °C we find that ΔG is positive and freezing is nonspontaneous. When the temperature is exactly 0 °C, $\Delta G = 0$ and an ice–water mixture exists in a condition of equilibrium. As long as heat isn't added or removed from the system, neither freezing nor melting is spontaneous and the ice and liquid water can exist together indefinitely.

Equilibrium and Work

We have identified ΔG as a quantity that specifies the amount of work that is available from a system. Since ΔG is zero at equilibrium, the amount of work available is zero also. Therefore, when a system is at equilibrium, no work can be extracted from it. As an example, consider again the common lead storage battery that we use to start our cars.

When the battery is fully charged, there are virtually no products of the discharge reaction present. The chemical reactants, however, are present in large amounts. Therefore, the total free energy of the reactants far exceeds the total free energy of products and, since $\Delta G = G_{\text{products}} - G_{\text{reactants}}$, the ΔG of the system has a large negative value. This means that a lot of energy is available to do work. As the battery discharges, the reactants are converted to products and G_{products} gets larger while $G_{\text{reactants}}$ gets smaller; thus ΔG becomes less negative, and less energy is available to do work. Finally, the battery reaches equilibrium. The total free energies of the reactants and the products have become equal, so $G_{\text{products}} - G_{\text{reactants}} = 0$ and $\Delta G = 0$. No further work can be extracted and we say the battery is "dead."

Estimating Melting and Boiling Points

For a phase change such as $H_2O(l) \longrightarrow H_2O(s)$, equilibrium can only exist at one particular temperature at atmospheric pressure. For water, that temperature is 0 °C. Above 0 °C, only liquid water can exist, and below 0 °C all the liquid will freeze to give ice. This yields an interesting relationship between ΔH and ΔS for a phase change. Since $\Delta G = 0$,

$$\Delta G = 0 = \Delta H - T\Delta S$$

Therefore,

$$\Delta H = T\Delta S$$

and

$$\Delta S = \frac{\Delta H}{T} \tag{19.8}$$

Thus, if we know ΔH for the phase change and the temperature at which the two phases coexist, we can calculate ΔS for the phase change. Another interesting relationship that we can obtain is

$$T = \frac{\Delta H}{\Delta S} \tag{19.9}$$

Thus, if we know ΔH and ΔS, we can calculate the temperature at which equilibrium will occur.

Example 19.7

Calculating the Equilibrium Temperature for a Phase Change

For the phase change $Br_2(l) \longrightarrow Br_2(g)$, $\Delta H° = +31.0$ kJ mol^{-1} and $\Delta S° = 92.9$ J mol^{-1} K^{-1}. Assuming that ΔH and ΔS are nearly temperature independent, calculate the approximate Celsius temperature at which $Br_2(l)$ will be in equilibrium with $Br_2(g)$ at 1 atm (i.e., the normal boiling point of liquid Br_2).

- **Analysis:** The normal boiling point of a substance is the temperature at which the liquid and gas phases are in equilibrium at one atmosphere of pressure; see Section 12.6. The wording of the problem strongly suggests that we can substitute $\Delta H°$ and $\Delta S°$ for ΔH and ΔS, respectively. If we do that we can use the equations we just discussed.

- **Assembling the Tools:** The temperature at which equilibrium exists is given by Equation 19.9. When we assume that ΔH and ΔS do not depend much on temperature, then we can use $\Delta H°$ and $\Delta S°$ in this equation to approximate the boiling point. That is,

$$T \approx \frac{\Delta H°}{\Delta S°}$$

- ΔH and ΔS do not change much with changes in temperature. This is because temperature changes affect the enthalpies and entropies of both the reactants and products by about the same amount, so the differences between reactants and products stays fairly constant.

- **Solution:** Substituting the data given in the problem,

$$\begin{aligned} T &\approx \frac{3.10 \times 10^4 \ \cancel{\text{J}} \ \cancel{\text{mol}^{-1}}}{92.9 \ \cancel{\text{J}} \ \cancel{\text{mol}^{-1}} \ \text{K}^{-1}} \\ &= 334 \text{ K} \end{aligned}$$

The Celsius temperature is 334 − 273 = 61 °C. Notice that we were careful to express $\Delta H°$ in joules, not kilojoules, so the units would cancel correctly. It is also interesting that the boiling point we calculated is quite close to the measured normal boiling point of 58.8 °C.

- **Is the Answer Reasonable?** The $\Delta H°$ value equals 31,000 and the $\Delta S°$ value equals approximately 100, which means the temperature should be about 310 K. Our value, 334 K, is not far from that, so the answer is reasonable.

Practice Exercises

19.17 | The heat of vaporization of ammonia is 21.7 kJ mol^{-1} and the boiling point of ammonia is −33.3 °C. Estimate the entropy change for the vaporization of liquid ammonia. (*Hint*: What algebraic sign do we expect for this entropy change?)

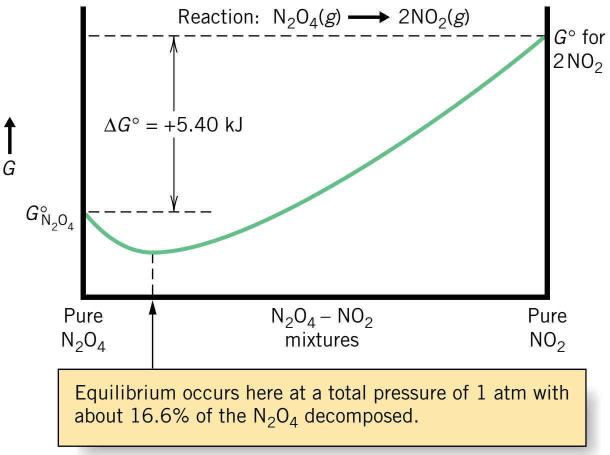
19.18 | The heat of vaporization of mercury is 60.7 kJ/mol. For $Hg(l)$, $S° = 76.1$ J mol^{-1} K^{-1}, and for $Hg(g)$, $S° = 175$ J mol^{-1} K^{-1}. Estimate the normal boiling point of liquid mercury.

Free Energy Diagrams

One way to gain a better understanding of how the free energy changes during a reaction is by studying **free energy diagrams**. As an example, let's study a reaction you've seen before—the decomposition of N_2O_4 into NO_2.

$$N_2O_4(g) \longrightarrow 2NO_2(g)$$

In our discussion of chemical equilibrium in Chapter 15 (page 698), we noted that equilibrium in this system can be approached from *either* direction, with the same equilibrium concentrations being achieved provided we begin with the same overall system composition.



Equilibrium occurs here at a total pressure of 1 atm with about 16.6% of the N_2O_4 decomposed.

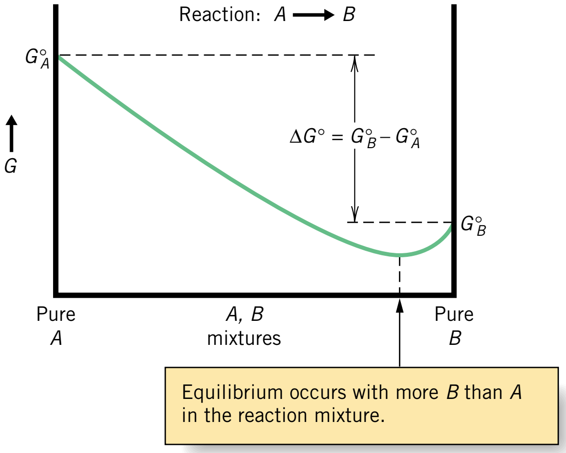
Figure 19.16 | **Free energy diagram for the decomposition of $N_2O_4(g)$.** The minimum on the curve indicates the composition of the reaction mixture at equilibrium. Because $\Delta G°$ is positive, the position of equilibrium lies close to the reactants. Not much product will form by the time the system reaches equilibrium.

Figure 19.16 shows the free energy diagram for the reaction, which depicts how the free energy changes as we proceed from the reactant to the product. On the left of the diagram we have the free energy of one mole of pure $N_2O_4(g)$, and on the right the free energy of two moles of pure $NO_2(g)$. Points along the horizontal axis represent mixtures of both substances. Notice that in going from reactant (N_2O_4) to product ($2NO_2$), the free energy has a minimum. It drops below that of either pure N_2O_4 or pure NO_2.

■ When a system moves "downhill" on its free energy curve, $G_{\text{final}} < G_{\text{initial}}$ and ΔG is negative. Changes with negative ΔG are spontaneous.

Any system will spontaneously seek the lowest point on its free energy curve. If we begin with pure $N_2O_4(g)$, the reaction will proceed from left to right and some $NO_2(g)$ will be formed, because proceeding in the direction of NO_2 leads to a lowering of the free energy. If we begin with pure $NO_2(g)$, a change also will occur. Going downhill on the free energy curve now takes place as the reverse reaction occurs [i.e., $2NO_2(g) \longrightarrow N_2O_4(g)$]. Once the bottom of the "valley" is reached, the system has come to equilibrium. As you learned in Sections 12.9 and 15.6, if the system isn't disturbed, the composition of the equilibrium mixture will remain constant. Now we see that the reason is because any change (moving either to the left or right) would require an uphill climb. Free energy increases are not spontaneous, so this doesn't happen.

An important thing to notice in Figure 19.16 is that some reaction takes place spontaneously in the forward direction even though $\Delta G°$ is positive. However, the reaction doesn't proceed far before equilibrium is reached. For comparison, Figure 19.17 shows the shape of the free energy curve for a reaction with a negative $\Delta G°$. We see here that at equilibrium there has been a much greater conversion of reactants to products. Thus, *$\Delta G°$ tells us where the position of equilibrium lies between pure reactants and pure products.*



Equilibrium occurs with more B than A in the reaction mixture.

Figure 19.17 | **Free energy curve for a reaction having a negative $\Delta G°$.** Because $G°_B$ is lower than $G°_A$, $\Delta G°$ is negative. This causes the position of equilibrium to lie far to the right, near the products. When the system reaches equilibrium, there will be a large amount of products present and few reactants.

$\Delta G°$ and the Position of Equilibrium

- When $\Delta G°$ is positive, the position of equilibrium lies close to the reactants and little reaction occurs by the time equilibrium is reached. The reaction will appear to be nonspontaneous.
- When $\Delta G°$ is negative, the position of equilibrium lies close to the products and a large amount of products will have formed by the time equilibrium is reached. The reaction will appear to be spontaneous.
- When $\Delta G° = 0$, the position of equilibrium will lie about midway between reactants and products. Substantial amounts of both reactants and products will be present when equilibrium is reached. The reaction will appear to be spontaneous whether we begin with pure reactants or pure products.

TOOLS

Using $\Delta G°$ to assess the position of equilibrium

$\Delta G°$ and the Position of Equilibrium

In general, the value of $\Delta G°$ for most reactions is much larger numerically than the $\Delta G°$ for the $N_2O_4 \longrightarrow NO_2$ reaction. In addition, the extent to which a reaction proceeds is very sensitive to the size of $\Delta G°$. If the $\Delta G°$ value for a reaction is reasonably large—about 20 kJ or more—almost no observable reaction will occur when $\Delta G°$ is positive. On the other hand, the reaction will go almost to completion if $\Delta G°$ is both large and negative.[5] From a practical standpoint, then, *the size and sign of $\Delta G°$ serve as indicators of whether an observable spontaneous reaction will occur.*

Example 19.8

Using $\Delta G°$ as a Predictor of the Outcome of a Reaction

Would we expect to be able to observe the following reaction at 25 °C?

$$NH_4Cl(s) \longrightarrow NH_3(g) + HCl(g)$$

■ **Analysis:** To answer this question we need to know the magnitude and algebraic sign of $\Delta G°$; that will allow us to estimate the position of equilibrium.

■ **Assembling the Tools:** The relationship between $\Delta G°$ and the position of equilibrium is one tool needed to answer this question. The other tool is Equation 19.7, which is needed to obtain the standard free energy change, $\Delta G°$.

■ **Solution:** First, let's calculate $\Delta G°$ for the reaction using the data in Table 19.2. The procedure is the same as that discussed earlier.

$$\begin{aligned}\Delta G° &= [G°_{f\,NH_3(g)} + \Delta G°_{f\,HCl(g)}] - [G°_{f\,NH_4Cl(s)}]\\ &= [(-16.7\text{ kJ}) + (-95.27\text{ kJ})] - [-203.9\text{ kJ}]\\ &= +91.9\text{ kJ}\end{aligned}$$

Because $\Delta G°$ is large and positive, only extremely small amounts of products can form at this temperature. Therefore, we would not expect to observe any decomposition of the NH_4Cl.

■ **Is the Answer Reasonable?** Be sure to check the algebraic signs of each term in the calculation. Also check that the free energies of the reactants are subtracted from those of the products. This problem involves adding (and subtracting) numbers. If we add all the raw numbers, without regard to sign, that should be our maximum possible positive answer. Similarly, the negative of this sum will be the largest possible negative value we could have. Our answer easily passes that test.

---

[5] As we discussed earlier, to actually see a change take place, the speed of a spontaneous reaction must be reasonably fast. For example, the decomposition of the nitrogen oxides into N_2 and O_2 is thermodynamically spontaneous ($\Delta G°$ is negative), but their rates of decomposition are so slow that these substances appear to be stable, and some are obnoxious air pollutants.

Practice Exercises

19.19 | Use the data in Table 19.2 to determine whether the reaction

$$SO_2(g) + O_2(g) \longrightarrow SO_3(g)$$

should "occur spontaneously" at 25 °C. (*Hint*: Be careful with algebraic signs.)

19.20 | Use the data in Table 19.2 to determine whether we should expect to see the formation of $CaCO_3(s)$ in the following reaction at 25 °C.

$$CaCl_2(s) + H_2O(g) + CO_2(g) \longrightarrow CaCO_3(s) + 2HCl(g)$$

$\Delta G°$ Varies with Temperature

So far, we have confined our discussion of the relationship of free energy and equilibrium to a special case, 25 °C. But what about other temperatures? Equilibria certainly can exist at temperatures other than 25 °C, and in Chapter 15 you learned how to apply Le Châtelier's principle to predict the way temperature affects the position of equilibrium. Now let's see how thermodynamics deals with this.

You've learned that at 25 °C the position of equilibrium is determined by the difference between the free energy of pure products and the free energy of pure reactants. This difference is given by $\Delta G°_{298}$, where we have now used the subscript "298" to indicate the temperature, 298 K. We define $\Delta G°_{298}$ as

$$\Delta G°_{298} = (G°_{\text{products}})_{298} - (G°_{\text{reactants}})_{298}$$

At temperatures other than 25 °C, it is still the difference between the free energies of the products and reactants that determines the position of equilibrium. We write this as $\Delta G°_T$. Thus, at a temperature other than 25 °C (298 K), we have

$$\Delta G°_T = (G°_{\text{products}})_T - (G°_{\text{reactants}})_T$$

where $(G°_{\text{products}})_T$ and $(G°_{\text{reactants}})_T$ are the total free energies of the pure products and reactants, respectively, at this other temperature.

Next, we must find a way to compute $\Delta G°_T$. Earlier we saw that $\Delta G°$ can be obtained from the equation

$$\Delta G° = \Delta H° - (298\text{ K})\,\Delta S°$$

At a different temperature, T, the equation becomes

$$\Delta G°_T = \Delta H°_T - T\Delta S°_T$$

Now we seem to be getting closer to our goal. If we can compute or estimate the values of $\Delta H°_T$ and $\Delta S°_T$ for a reaction, we have solved our problem.

The size of $\Delta G°_T$ obviously depends very strongly on the temperature—the equation above has temperature as one of its variables. However, as noted in the margin comment on page 895, the magnitudes of the ΔH and ΔS for a reaction are relatively insensitive to changes in temperature. Therefore, we can use $\Delta H°_{298}$ and $\Delta S°_{298}$ as reasonable approximations of $\Delta H°_T$ and $\Delta S°_T$. This allows us to rewrite the equation for $\Delta G°_T$ as

TOOLS

Calculating $\Delta G°$ at temperatures other than 25 °C

$$\Delta G°_T \approx \Delta H°_{298} - T\Delta S°_{298} \tag{19.10}$$

The following example illustrates how this equation is useful.

Example 19.9
$\Delta G°$ at Temperatures Other than 25 °C

Earlier we saw that at 25 °C the value of $\Delta G°$ for the reaction

$$N_2O_4(g) \longrightarrow 2NO_2(g)$$

has a value of +5.40 kJ. What is the approximate value of $\Delta G_T°$ for this reaction at 105 °C?

Analysis: In this problem we can't calculate $\Delta G°$ from standard free energies of formation because we only have such values for 25 °C. Therefore, we're going to have to use the alternative approach described above, which requires Equation 19.10 and values of $\Delta H°$ and $\Delta S°$.

Assembling the Tools: Equation 19.10 is the tool needed to solve the problem. To use it, we need values of $\Delta H°$ and $\Delta S°$. The $\Delta H°$ is calculated using Equation 7.13, Hess's law. The $\Delta S°$ is determined using Equation 19.6.

Using the data in Table 7.2 on page 285 we find the following standard heats of formation for use in Equation 7.13.

$N_2O_4(g)$ $\Delta H_f° = +9.67$ kJ/mol
$NO_2(g)$ $\Delta H_f° = +33.8$ kJ/mol

Next, we compute $\Delta S°$ for the reaction using absolute entropy data from Table 19.1.

$N_2O_4(g)$ $S° = 304$ J/mol K
$NO_2(g)$ $S° = 240.5$ J/mol K

Solution: First, we compute $\Delta H°$ using Hess's law and the data we just gathered:

$$\begin{aligned}\Delta H° &= [2\Delta H°_{f\,NO_2(g)}] - [\Delta H°_{f\,N_2O_4(g)}]\\ &= \left[2\ \cancel{\text{mol}} \times \left(\frac{33.8\text{ kJ}}{\cancel{\text{mol}}}\right)\right] - \left[1\ \cancel{\text{mol}} \times \left(\frac{9.67\text{ kJ}}{\cancel{\text{mol}}}\right)\right]\\ &= +57.9\text{ kJ}\end{aligned}$$

Next, we use Equation 19.6 to calculate $\Delta S°$

$$\begin{aligned}\Delta S° &= \left[2\ \cancel{\text{mol}} \times \left(\frac{240.5\text{ J}}{\cancel{\text{mol}}\text{ K}}\right)\right] - \left[1\ \cancel{\text{mol}} \times \left(\frac{304\text{ J}}{\cancel{\text{mol}}\text{ K}}\right)\right]\\ &= +177\text{ J K}^{-1}\text{ or }0.177\text{ kJ K}^{-1}\end{aligned}$$

The temperature is 105 °C, which is 378 K, so we can write the free energy change as $\Delta G°_{378}$. Substituting into Equation 19.10 using $T = 378$ K, we have

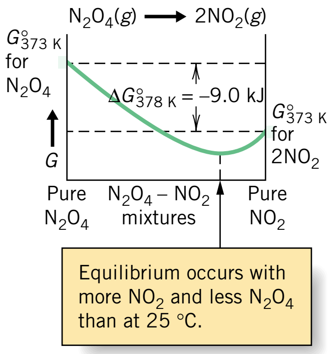
$$\begin{aligned}\Delta G°_{378} &\approx (+57.9\text{ kJ}) - (378\ \cancel{\text{K}})(0.177\text{ kJ }\cancel{\text{K}^{-1}})\\ &\approx -9.0\text{ kJ}\end{aligned}$$

Notice that the $\Delta G_T°$ has changed from +5.40 kJ at 25 °C to −9.0 at 105 °C.

Is the Answer Reasonable? As usual, we can double-check the algebraic signs to be sure we've performed the calculations correctly. For this problem, however, we can check that our answer makes sense based on Le Châtelier's principle.

Since the reaction is endothermic, heat may be written as a reactant:

$$\text{Heat} + N_2O_4(g) \rightleftharpoons 2NO_2(g)$$



$N_2O_4(g) \longrightarrow 2NO_2(g)$
$G°_{373\text{ K}}$ for N_2O_4
$\Delta G°_{378\text{ K}} = -9.0$ kJ
$G°_{373\text{ K}}$ for $2NO_2$
G
Pure N_2O_4
$N_2O_4 - NO_2$ mixtures
Pure NO_2

Equilibrium occurs with more NO_2 and less N_2O_4 than at 25 °C.

When heat is added, we expect the position of equilibrium to shift toward the products. The positive value of ΔG_T° at 25 °C means that the position of equilibrium lies nearest the reactants. When ΔG_T° has a negative value at 105 °C, it means that the position of equilibrium now lies closer to the products. The result is a shift in the position of equilibrium toward the products, in agreement with our expectations.

Practice Exercises

19.21 | In Example 19.4 we computed ΔH° and ΔS° for the reaction

$$CO(NH_2)_2(aq) + H_2O(l) \longrightarrow CO_2(g) + 2NH_3(g)$$

What is ΔG_T° for this reaction at 75 °C? (*Hint*: Be careful with the units.)

19.22 | Use the data in Table 19.2 to determine ΔG_{298}° for the reaction

$$2NaHCO_3(s) \longrightarrow Na_2CO_3(s) + CO_2(g) + H_2O(g)$$

Then calculate the approximate value for ΔG_{490}° for the reaction at 217 °C using the data in Tables 7.2 and 19.1. How does the position of equilibrium for this reaction change as the temperature is increased?

19.9 | Equilibrium Constants and ΔG°

In the preceding discussion, you learned in a qualitative way that the position of equilibrium in a reaction is determined by the sign and magnitude of ΔG°. You also learned that the direction in which a reaction proceeds depends on where the system composition stands relative to the minimum on the free energy curve. Thus, the reaction will proceed spontaneously in the forward direction only if it will lead to a lowering of the free energy (i.e., if ΔG is negative).

Quantitatively, the relationship between ΔG and ΔG° is expressed by the following equation, which we will not attempt to justify.

TOOLS

Relating the reaction quotient to ΔG

$$\Delta G = \Delta G^\circ + RT \ln Q \tag{19.11}$$

■ In Chapter 15 we defined Q as the *reaction quotient*, the numerical value of the mass action expression.

Here R is the gas constant in appropriate energy units (i.e., 8.314 J mol^{-1} K^{-1}), T is the Kelvin temperature, and ln Q is the natural logarithm of the reaction quotient that was introduced in Section 15.2. For gaseous reactions, Q is calculated using partial pressures expressed in atm;[6] for reactions in solution, Q is calculated from molar concentrations. Equation 19.11 allows us to predict the direction of the spontaneous change in a reaction mixture if we know ΔG° and the composition of the mixture, as illustrated in Example 19.10.

Example 19.10
Determining the Direction of a Spontaneous Reaction

■ In Chapter 15, you learned that you can also predict the direction of a reaction by comparing Q with K (page 723).

The reaction $2NO_2(g) \rightleftharpoons N_2O_4(g)$ has $\Delta G_{298}^\circ = -5.40$ kJ per mole of N_2O_4. In a reaction mixture, the partial pressure of NO_2 is 0.25 atm and the partial pressure of N_2O_4 is 0.60 atm. In which direction must this reaction proceed, at 25 °C, to reach equilibrium?

■ **Analysis:** Since we know that reactions proceed spontaneously *toward* equilibrium, we are really being asked to determine whether the reaction will proceed spontaneously in the forward or reverse direction. In Chapter 15 we learned that when we compare Q to K we can determine in which direction a reaction will proceed. Determining the sign of ΔG will also allow us to predict the direction of a chemical reaction.

---

[6] Strictly speaking, we should express pressures in atm or bar depending on which was used to obtain the ΔG° data. For simplicity, we will use the more familiar pressure unit atm in all our calculations. Because the atm and bar differ by only about 1 percent, any errors that might be introduced will be very small.

■ **Assembling the Tools:** We can use Equation 19.11 to calculate ΔG for the forward reaction. If ΔG is negative, then the forward reaction is spontaneous. However, if the calculated ΔG is positive, the forward reaction is nonspontaneous and it is really the reverse reaction that is spontaneous. To solve Equation 19.11 we need the correct form for the mass action expression so we can calculate Q. Expressed in terms of partial pressures, the mass action expression defines Q for this reaction:

$$Q = \frac{P_{N_2O_4}}{P_{NO_2}^2}$$

■ **Solution:** Using the mass action expression for Q, the equation we will use is

$$\Delta G = \Delta G° + RT \ln\left(\frac{P_{N_2O_4}}{P_{NO_2}^2}\right)$$

Next, let's assemble the data:

$$\begin{aligned} \Delta G°_{298} &= -5.40 \text{ kJ mol}^{-1} & T &= 298 \text{ K} \\ &= -5.40 \times 10^3 \text{ J mol}^{-1} & P_{N_2O_4} &= 0.60 \text{ atm} \\ R &= 8.314 \text{ J mol}^{-1}\text{K}^{-1} & P_{NO_2} &= 0.25 \text{ atm} \end{aligned}$$

Notice that we have changed the energy units of $\Delta G°$ to joules so they will be the same as the energy units in the R we are using. The next step is to substitute the data into the equation for ΔG. In doing this, we leave off the units for the partial pressures because reaction quotients are always unitless quantities.[7] Here is the calculation.[8]

$$\begin{aligned} \Delta G &= -5.40 \times 10^3 \text{ J mol}^{-1} + (8.314 \text{ J mol}^{-1}\ \cancel{\text{K}^{-1}})(298\ \cancel{\text{K}}) \ln\left[\frac{0.60}{(0.25)^2}\right] \\ &= -5.40 \times 10^3 \text{ J mol}^{-1} + (8.314 \text{ J mol}^{-1}\ \cancel{\text{K}^{-1}})(298\ \cancel{\text{K}}) \ln(9.6) \\ &= -5.40 \times 10^3 \text{ J mol}^{-1} + (8.314 \text{ J mol}^{-1}\ \cancel{\text{K}^{-1}})(298\ \cancel{\text{K}})(2.26) \\ &= -5.40 \times 10^3 \text{ J mol}^{-1} + 5.60 \times 10^3 \text{ J mol}^{-1} \\ &= +2.0 \times 10^2 \text{ J mol}^{-1} \end{aligned}$$

Since ΔG is positive, the forward reaction is nonspontaneous. The reverse reaction is the one that will occur, and to reach equilibrium, some N_2O_4 will have to decompose.

■ **Is the Answer Reasonable?** There is no simple check. However, we can check to be sure the energy units in both terms on the right are the same. Notice that here we have changed the units for $\Delta G°$ to joules to match those of R. Also notice that the temperature is expressed in kelvins, to match the temperature units in R.

---

[7] For reasons beyond the scope of this text, quantities in mass action expressions used to compute reaction quotients and equilibrium constants are actually ratios. For partial pressures, it's the pressure in atm divided by 1 atm; for concentrations, it's the molarity divided by 1 *M*. This causes the units to cancel to give a unitless value for Q or K.

[8] As we noted in the footnote on page 655, when taking the logarithm of a quantity, the number of digits *after the decimal point* should equal the number of significant figures in the quantity. Since 0.60 atm and 0.25 atm both have two significant figures, the logarithm of the quantity in square brackets (2.26) is rounded to give two digits after the decimal point.

Practice Exercises

19.23 | Calculate ΔG for the reaction described in the preceding example if the partial pressure of NO_2 is 0.260 atm and the partial pressure of N_2O_4 is 0.598 atm. Where does the system stand relative to equilibrium? (*Hint*: What is ΔG for a system at equilibrium?)

19.24 | In which direction will the reaction described in Example 19.10 proceed to reach equilibrium if the partial pressure of NO_2 is 0.60 atm and the partial pressure of N_2O_4 is 0.25 atm?

Computing Thermodynamic Equilibrium Constants

Earlier you learned that when a system reaches equilibrium the free energy of the products equals the free energy of the reactants and ΔG equals zero. We also know that at equilibrium the reaction quotient equals the equilibrium constant.

$$\text{At equilibrium} \quad \begin{cases} \Delta G = 0 \\ Q = K \end{cases}$$

If we substitute these into Equation 19.11, we obtain

$$0 = \Delta G^\circ + RT \ln K$$

which can be rearranged to give

$$\Delta G^\circ = -RT \ln K \tag{19.12}$$

Determining thermodynamic equilibrium constants

The equilibrium constant K calculated from this equation is called the **thermodynamic equilibrium constant** and corresponds to K_p for reactions involving gases (with partial pressures expressed in atm) and to K_c for reactions in solution (with concentrations expressed in mol L^{-1}).[9]

Equation 19.12 is useful because it permits us to determine equilibrium constants from either measured or calculated values of ΔG°. As you know, ΔG° can be determined by a Hess's law type of calculation from tabulated values of ΔG_f°. It also allows us to obtain values of ΔG° from measured equilibrium constants.

Example 19.11
Calculating the Gibbs Free Energy Change

The brownish haze often associated with air pollution is caused by nitrogen dioxide, NO_2, a red-brown gas. Nitric oxide, NO, is formed in automobile engines and some of it escapes into the air where it is oxidized to NO_2 by oxygen.

$$2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g)$$

The value of K_p for this reaction is 1.7×10^{12} at 25.00 °C. What is ΔG° for the reaction, (a) expressed in joules per mole and (b) in kilojoules per mole?

■ **Analysis:** We have an equation that relates the equilibrium constant to the standard free energy. All we have to do is collect the appropriate information to perform the calculation.

---

[9] The thermodynamic equilibrium constant requires that gases *always* be included as partial pressures in mass action expressions. The pressure units must be standard pressure units (atmospheres or bars, depending on which convention was used for collecting the ΔG° data. For a heterogeneous equilibrium involving a gas and a substance in solution, the mass action expression will mix partial pressures (for the gas) with molarities (for the dissolved substance).

Assembling the Tools: The relationship between the standard free energy change, $\Delta G°$, and an equilibrium constant is expressed in Equation 19.12.

$$\Delta G° = -RT \ln K_p$$

We'll need the data below to calculate $\Delta G°$. Note that the temperature is given to the nearest hundredth of a degree, so we'll use $T_K = t_C + 273.15$ to compute the Kelvin temperature.

$$\begin{aligned} R &= 8.314 \text{ J mol}^{-1} \text{ K}^{-1} \\ T &= 298.15 \text{ K} \\ K_p &= 1.7 \times 10^{12} \end{aligned}$$

Solution: (a) Substituting these values into the equation, we have

$$\begin{aligned} \Delta G° &= -(8.314 \text{ J mol}^{-1} \text{ K}^{-1} \times 298.15 \text{ K}) \ln (1.7 \times 10^{12}) \\ &= -(8.314 \text{ J mol}^{-1} \text{ K}^{-1} \times 298.15 \text{ K}) \times (28.16) \\ &= -6.980 \times 10^4 \text{ J mol}^{-1} \text{ (to four significant figures)} \end{aligned}$$

(b) Changing J to kJ,

$$\Delta G° = -69.80 \text{ kJ mol}^{-1}$$

Is the Answer Reasonable? The value of K_p tells us that the position of equilibrium lies far to the right, which means $\Delta G°$ must be large and negative. Therefore, the answer, -69.80 kJ mol^{-1}, seems reasonable.

The units in this calculation give $\Delta G°$ on a per mole (mol^{-1}) basis. This reminds us that we are viewing the coefficients of the reactants and products as representing moles, rather than some other sized quantity.

Example 19.12
Thermodynamic Equilibrium Constants

Sulfur dioxide, which is sometimes present in polluted air, reacts with oxygen when it passes over the catalyst in automobile catalytic converters. The product is the very acidic oxide, sulfur trioxide.

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

For this reaction, $\Delta G° = -1.40 \times 10^2$ kJ mol^{-1} at 25 °C. What is the value of K_p?

Analysis: Once again we have an equation that we can solve once we collect all of the data for the equation's variables.

Assembling the Tools: We will use Equation 19.12.

$$\Delta G° = -RT \ln K_p$$

The chemical equation, in this case, is extra information. We see from the equation that we need to find T and $\Delta G°$ in the statement of the problem, and if necessary look up the value for R. We can list our data as

$$\begin{aligned} R &= 8.314 \text{ J mol}^{-1} \text{ K}^{-1} \\ T &= 298 \text{ K} \\ \Delta G° &= -1.40 \times 10^2 \text{ kJ mol}^{-1} \\ &= -1.40 \times 10^5 \text{ J mol}^{-1} \end{aligned}$$

To make the units cancel correctly, we have added the unit mol^{-1} to the value of $\Delta G°$. This just emphasizes that the amounts of reactants and products are specified in mole-sized quantities.

■ **Solution:** To calculate K_p, let's first solve for $\ln K_p$.

$$\ln K_p = \frac{-\Delta G°}{RT}$$

Substituting values gives

$$\begin{aligned}\ln K_p &= \frac{-(-1.40 \times 10^5\ \cancel{\text{J}}\ \cancel{\text{mol}^{-1}})}{(8.314\ \cancel{\text{J}}\ \cancel{\text{mol}^{-1}}\ \cancel{\text{K}^{-1}})(298\ \cancel{\text{K}})} \\ &= +56.5\end{aligned}$$

To calculate K_p, we take the antilogarithm,

$$\begin{aligned}K_p &= e^{56.5} \\ &= 3 \times 10^{24}\end{aligned}$$

Notice that we have expressed the answer to only one significant figure. As discussed earlier, when taking a logarithm, the number of digits written after the decimal place equals the number of significant figures in the number. Conversely, the number of significant figures in the antilogarithm equals the number of digits after the decimal in the logarithm.

■ **Is the Answer Reasonable?** The value of $\Delta G°$ is large and negative, so the position of equilibrium should favor the products. The large value of K_p also indicates that the products are favored and, therefore, the result is reasonable.

Practice Exercises

19.25 | The reaction $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$ has $K_p = 6.9 \times 10^5$ at 25.0 °C. Calculate $\Delta G°$ for this reaction in units of kilojoules. (*Hint*: Be careful with units and significant figures.)

19.26 | The reaction $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$ has $\Delta G° = +3.3$ kJ mol^{-1} at 25.0 °C. What is the value of K_p at this temperature?

19.10 | Bond Energies

You have seen how thermodynamic data allow us to predict the spontaneity of chemical reactions as well as the nature of chemical systems at equilibrium. In addition to these useful and important benefits of the study of thermodynamics, there is a bonus. By studying heats of reaction, and heats of formation in particular, we can obtain fundamental information about the chemical bonds in the substances that react. The reasoning is that a chemical reaction results in products that have different bonds than the reactants did. The difference in the total energy of the bonds in the products compared to the total energy of the bonds in the reactants shows up as heat that is lost or gained.

Recall that the **bond energy** is the *amount of energy needed to break a chemical bond to give electrically neutral fragments*. It is a useful quantity to know in the study of chemical properties, because during chemical reactions, bonds within the reactants are broken and new ones are formed as the products appear. The first step—bond breaking—is one of the factors that controls the reactivity of substances. Elemental nitrogen, for example, has a very low degree of reactivity, which is generally attributed to the very strong triple bond in N_2. Reactions that involve the breaking of this bond in a single step simply do not occur. When N_2 does react, it is by a stepwise involvement of its three bonds, one at a time.

■ The heats of formation of the nitrogen oxides are endothermic because of the large bond energy of the N_2 molecule.

Determining Bond Energies

The bond energies of simple diatomic molecules such as H_2, O_2, and Cl_2 are usually measured *spectroscopically*. A flame or an electric spark is used to excite (energize) the molecules, causing them to emit light. An analysis of the spectrum of emitted light allows scientists to compute the amount of energy needed to break the bond.

For more complex molecules, thermochemical data can be used to calculate bond energies in a Hess's law kind of calculation. We will use the standard heat of formation of methane to illustrate how this is accomplished. However, before we can attempt such a calculation, we must first define a thermochemical quantity that we will call the **atomization energy**, symbolized ΔH_{atom}. This is the amount of energy needed to rupture all the chemical bonds in one mole of gaseous molecules to give gaseous atoms as products. For example, the atomization of methane is

$$CH_4(g) \longrightarrow C(g) + 4H(g)$$

■ The kind of bond breaking described here divides the electrons of the bond equally between the two atoms. It could be symbolized as

$$A:B \longrightarrow A\cdot + \cdot B$$

and the enthalpy change for the process is ΔH_{atom}. For this particular molecule, ΔH_{atom} corresponds to the total amount of energy needed to break all the C—H bonds in one mole of CH_4; therefore, division of ΔH_{atom} by 4 would give the average C—H bond energy in methane, expressed in kJ mol^{-1}.

Figure 19.18 shows how we can use the standard heat of formation, ΔH_f°, to calculate the atomization energy. Across the bottom we have the chemical equation for the formation of CH_4 from its elements. The enthalpy change for this reaction, of course, is ΔH_f°. In this figure we also can see an alternative three-step path that leads to $CH_4(g)$. One step is the breaking of H—H bonds in the H_2 molecules to give gaseous hydrogen atoms, another is the vaporization of carbon to give gaseous carbon atoms, and the third is the combination of the gaseous atoms to form CH_4 molecules. These changes are labeled 1, 2, and 3 in the figure.

Since $\Delta H = H_{\text{final}} - H_{\text{initial}}$, a difference in state functions, the net enthalpy change from one state to another is the same regardless of the path that we follow. This means that the sum of the enthalpy changes along the upper path must be the same as the enthalpy change along the lower path, ΔH_f°. Perhaps this can be more easily seen in Hess's law terms if we write the changes along the upper path in the form of thermochemical equations.

Steps 1 and 2 have enthalpy changes that are called *standard heats of formation of gaseous atoms.* Values for these quantities have been measured for many of the elements, and some are given in Table 19.3. Step 3 is the opposite of atomization, and

Table 19.3 Standard Heats of Formation of Some Gaseous Atoms from the Elements in Their Standard States

Atom	ΔH_f° per mole of atoms (kJ mol^{-1})[a]
H	217.89
Li	161.5
Be	324.3
B	560
C	716.67
N	472.68
O	249.17
S	276.98
F	79.14
Si	450
P	332.2
Cl	121.47
Br	112.38
I	107.48

[a] All values are positive because forming the gaseous atoms from the elements involves bond breaking and is endothermic.

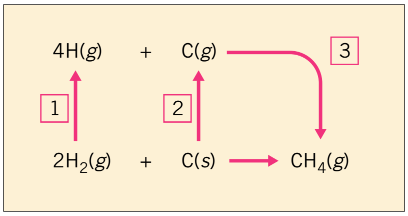


Figure 19.18 | **Two paths for the formation of methane from its elements in their standard states.** As described in the text, steps 1, 2, and 3 of the upper path involve the formation of gaseous atoms of the elements and the formation of bonds in CH_4. The lower path corresponds to the direct combination of the elements in their standard states to give CH_4. Because H is a state function, the sum of the enthalpy changes along the upper path must equal the enthalpy change for the lower path (ΔH_f°).

■ A more complete table of standard heats of formation of gaseous atoms is located in Appendix C.3.

its enthalpy change will therefore be the negative of ΔH_{atom} (recall that if we reverse a reaction, we change the sign of its ΔH).

$$\begin{array}{lrl}
\text{(Step 1)} & 2H_2(g) \longrightarrow 4H(g) & \Delta H_1^\circ = 4\Delta H^\circ_{\text{f }H(g)} \\
\text{(Step 2)} & C(s) \longrightarrow C(g) & \Delta H_2^\circ = \Delta H^\circ_{\text{f }C(g)} \\
\text{(Step 3)} & 4H(g) + C(g) \longrightarrow CH_4(g) & \Delta H_3^\circ = -\Delta H_{\text{atom}} \\
\hline
 & 2H_2(g) + C(s) \longrightarrow CH_4(g) & \Delta H^\circ = \Delta H^\circ_{\text{f }CH_4(g)}
\end{array}$$

Notice that by adding the first three equations, $C(g)$ and $4H(g)$ cancel and we get the equation for the formation of CH_4 from its elements in their standard states. This means that adding the ΔH° values of the first three equations should give ΔH_f° for CH_4

$$\Delta H_1^\circ + \Delta H_2^\circ + \Delta H_3^\circ = \Delta H^\circ_{\text{f }CH_4(g)}$$

Let's substitute for ΔH_1°, ΔH_2°, and ΔH_3°, and then solve for ΔH_{atom}. First, we substitute for the ΔH° quantities:

$$4\Delta H^\circ_{\text{f }H(g)} + \Delta H^\circ_{\text{f }C(g)} + (-\Delta H_{\text{atom}}) = \Delta H^\circ_{\text{f }CH_4(g)}$$

Next, we solve for $(-\ \Delta H_{\text{atom}})$:

$$-\Delta H_{\text{atom}} = \Delta H^\circ_{\text{f }CH_4(g)} - 4\Delta H^\circ_{\text{f }H(g)} - \Delta H^\circ_{\text{f }C(g)}$$

Changing signs and rearranging the right side of the equation just a bit gives

$$\Delta H_{\text{atom}} = 4\Delta H^\circ_{\text{f }H(g)} + \Delta H^\circ_{\text{f }C(g)} - \Delta H^\circ_{\text{f }CH_4(g)}$$

Now all we need are the ΔH_f° values for the substances indicated on the right side. From Table 19.3 we obtain $\Delta H^\circ_{\text{f }H(g)}$ and $\Delta H^\circ_{\text{f }C(g)}$, and the value of $\Delta H^\circ_{\text{f }CH_4(g)}$ is obtained from Table 7.2. We will round these to the nearest 0.1 kJ/mol.

$$\begin{aligned}
\Delta H^\circ_{\text{f }H(g)} &= +217.9 \text{ kJ/mol} \\
\Delta H^\circ_{\text{f }C(g)} &= +716.7 \text{ kJ/mol} \\
\Delta H^\circ_{\text{f }CH_4(g)} &= -74.8 \text{ kJ/mol}
\end{aligned}$$

Substituting these values gives

$$\Delta H_{\text{atom}} = 1663.1 \text{ kJ/mol}$$

and division by 4 gives an estimate of the average C—H bond energy in this molecule.

$$\begin{aligned}
\text{Bond energy} &= \frac{1663.1 \text{ kJ/mol}}{4} \\
&= 415.8 \text{ kJ/mol of C—H bonds}
\end{aligned}$$

This value is quite close to the one in Table 19.4, which is an average of the C—H bond energies in many different compounds. The other bond energies in Table 19.4 are also based on thermochemical data and were obtained by similar calculations.

Table 19.4 Some Average Bond Energies

Bond	Bond Energy (kJ mol^{-1})	Bond	Bond Energy (kJ mol^{-1})
C—C	348	C—Br	276

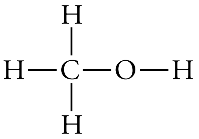
C—Cl	338	H—Si	376

Estimating Heats of Formation

An amazing thing about many covalent bond energies is that they are very nearly the same in many different compounds. This suggests, for example, that a C—H bond is very nearly the same in CH_4 as it is in C_3H_6 or $C_{15}H_{32}$ or a large number of other compounds that contain this kind of bond.

Because the bond energy doesn't vary much from compound to compound, we can use tabulated bond energies to estimate the heats of formation of substances. For example, let's calculate the standard heat of formation of methyl alcohol vapor, $CH_3OH(g)$. The structural formula for methanol is



$$\mathrm{H{-}\overset{\displaystyle H}{\underset{\displaystyle H}{C}}{-}O{-}H}$$

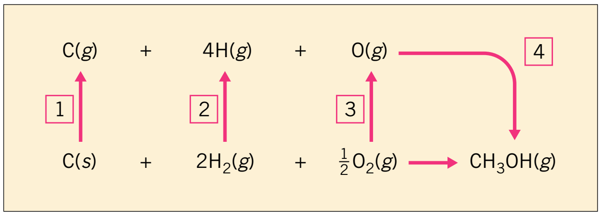


Figure 19.19 | **Two paths for the formation of methyl alcohol vapor from its elements in their standard states.** The numbered paths are discussed in the text.

To perform this calculation, we set up two paths from the elements to the compound, as shown in Figure 19.19. The lower path has an enthalpy change corresponding to $\Delta H^\circ_{\mathrm{f}\ CH_3OH(g)}$, while the upper path takes us to the gaseous elements and then through the energy released when the bonds in the molecule are formed. This latter energy can be computed from the bond energies in Table 19.4. As before, the sum of the energy changes along the upper path must be the same as the energy change along the lower path, and this permits us to compute $\Delta H^\circ_{\mathrm{f}\ CH_3OH(g)}$.

Steps 1, 2, and 3 involve the formation of the gaseous atoms from the elements, and their enthalpy changes are obtained from Table 19.3.

$$\Delta H^\circ_1 = \Delta H^\circ_{\mathrm{f}\ C(g)} = 1\ \text{mol} \times 716.7\ \text{kJ/mol} = 716.7\ \text{kJ}$$

$$\Delta H^\circ_2 = 4\Delta H^\circ_{\mathrm{f}\ H(g)} = 4\ \text{mol} \times (217.9\ \text{kJ/mol}) = 871.6\ \text{kJ}$$

$$\Delta H^\circ_3 = \Delta H^\circ_{\mathrm{f}\ O(g)} = 1\ \text{mol} \times (249.2\ \text{kJ/mol}) = 249.2\ \text{kJ}$$

The sum of these values, +1837.5 kJ, is the total energy-input (the net ΔH°) for the first three steps.

The formation of the CH_3OH molecule from the gaseous atoms is exothermic because *energy is always released* when atoms become joined by covalent bonds. In this molecule we can count three C—H bonds, one C—O bond, and one O—H bond. Their formation releases energy equal to their bond energies, which we obtain from Table 19.4.

Bond	Energy (kJ)
3(C—H)	3 × (412 kJ/mol) = 1236
C—O	360
O—H	463

Adding these together gives a total of 2059 kJ. Therefore, for Step 4 in Figure 19.19 the enthalpy, ΔH°_4, is −2059 kJ (because bond formation is exothermic). Now we can compute the total enthalpy change for the upper path.

$$\begin{aligned}\Delta H^\circ &= (+1837.5\ \text{kJ}) + (-2059\ \text{kJ})\\ &= -222\ \text{kJ}\end{aligned}$$

The value just calculated should be equal to $\Delta H^\circ_\mathrm{f}$ for $CH_3OH(g)$. For comparison, it has been found experimentally that $\Delta H^\circ_\mathrm{f}$ for this molecule (in the vapor state) is −201 kJ/mol. At first glance, the agreement doesn't seem very good, but on a relative basis the calculated value (−222 kJ) differs from the experimental one by only about 10%.

Practice Exercises

19.27 | Determine the heat of formation of gaseous 1-propanol ($CH_3CH_2CH_2OH$) and 2-bromobutane ($CH_3CHBrCH_2CH_3$). (*Hint*: Remember that bond formation is exothermic.)

19.28 | Determine the heat of formation of gaseous cyclohexane, C_6H_{12}. Cyclohexane is a six-member carbon ring with two hydrogen atoms attached to each carbon atom. Do the same for benzene, C_6H_6. (See Section 9.9, page 397 for the structure.)

Summary

First Law of Thermodynamics. The change in the **internal energy** of a system, ΔE, equals the sum of the heat absorbed by the system, q, and the work done on the system, w. ΔE does not depend on the path from E_{initial} to E_{final}, whereas q and w do depend on the path taken. For pressure–volume work, $w = -P\Delta V$, where P is the external pressure and $\Delta V = V_{\text{final}} - V_{\text{initial}}$. The heat at constant volume, q_v, is equal to ΔE, whereas the heat at constant pressure, q_p, is equal to ΔH. The value of ΔH differs from ΔE by the work expended in pushing back the atmosphere when the change occurs at constant atmospheric pressure. In general, the difference between ΔE and ΔH is quite small. For a chemical reaction, $\Delta H = \Delta E + \Delta n_{\text{gas}} RT$, where Δn_{gas} is the change in the number of moles of gas when going from reactants to products.

Spontaneity. A **spontaneous change** occurs without outside assistance, whereas a nonspontaneous changes requires continuous help and can occur only if it is accompanied by and linked to some other spontaneous event.

Spontaneity is associated with statistical probability—spontaneous processes tend to proceed from lower probability states to those of higher probability. The thermodynamic quantity associated with the probability of a state is **entropy, *S*.** Entropy is a state function that is a measure of the number of energetically equivalent ways, microstates, W, a state can be realized. In general, gases have much higher entropies than liquids, which have somewhat higher entropies than solids. Entropy increases with volume for a gas and with the temperature. During a chemical reaction, the entropy tends to increase if the number of molecules increases.

Second Law of Thermodynamics. This law states that the entropy of the universe (system plus surroundings) increases whenever a spontaneous change occurs.

Gibbs Free Energy. The **Gibbs free energy**, G, is a state function and its change, ΔG, allows us to determine the combined effects of enthalpy and entropy changes on the spontaneity of a chemical or physical change. A change is spontaneous only if the free energy of the system decreases (ΔG is negative). When ΔH and ΔS have the same algebraic sign, the temperature becomes the critical factor in determining spontaneity.

Third Law of Thermodynamics. The entropy of a pure crystalline substance is equal to zero at absolute zero (0 K). Standard entropies, $S°$, are calculated for 25 °C and 1 atm (Table 19.1) and can be used to calculate $\Delta S°$ for chemical reactions.

Standard Free Energy Changes. When ΔG is measured at 25 °C and 1 atm, it is the **standard free energy change, $\Delta G°$. Standard free energies of formation,** $\Delta G_f°$, can be used to obtain $\Delta G°$ for chemical reactions by a Hess's law type of calculation.

For any system, the value of ΔG is equal to the maximum amount of energy that can be obtained in the form of useful work, which can be obtained only if the change takes place by a **reversible process.** All real changes are irreversible and we always obtain less work than is theoretically available; the rest is lost as heat.

Free Energy and Equilibrium. When a system reaches equilibrium, $\Delta G = 0$ and no useful work can be obtained from it. For a phase change (e.g., solid $\rightleftharpoons$ liquid) ΔS and ΔH are related by the equation $\Delta S = \Delta H/T$, where T is the temperature at which the two phases are in equilibrium.

In chemical reactions, equilibrium occurs at a minimum on the free energy curve part way between pure reactants and pure products. The composition of the equilibrium mixture is determined by where the minimum lies along the reactant $\longrightarrow$ product axis; when it lies close to the products, the proportion of product to reactants is large and the reaction goes far toward completion.

When a reaction has a value of $\Delta G°$ that is both large and negative, it will appear to occur spontaneously because a lot of products will be formed by the time equilibrium is reached. If $\Delta G°$ is large and positive, it may be difficult to observe any reaction at all because only tiny amounts of products will be formed.

Thermodynamic Equilibrium Constants. The spontaneity of a reaction is determined by ΔG (how the free energy changes with a change in concentration). This is related to the standard free energy change, $\Delta G°$, by the equation $\Delta G = \Delta G° + RT \ln Q$, where Q is the reaction quotient for the system. At equilibrium, $\Delta G° = -RT \ln K$, where $K = K_p$ for gaseous reactions and $K = K_c$ for reactions in solution.

Bond Energies and Heats of Reaction. The **bond energy** equals the amount of energy needed to break a bond to give neutral fragments. The sum of all the bond energies in a molecule is the **atomization energy, ΔH_{atom},** and, on a mole basis, it corresponds to the energy needed to break one mole of molecules into individual atoms. The heat of formation of a gaseous compound equals the sum of the energies needed to form atoms of the elements that are found in the substance plus the negative of the atomization energy.

Tools for Problem Solving

In this chapter you learned to apply the following concepts as tools in solving problems related to thermodynamics. When faced with solving a problem, recall what each tool does and consider whether it will be helpful in finding a solution.

Converting between ΔE and ΔH (page 873)

Use the following equation when you need to find the difference between ΔE and ΔH, or when converting from one to the other.

$$\Delta H = \Delta E + \Delta n_{\text{gas}} RT$$

Use the coefficients of gaseous reactants and products to calculate Δn_{gas}.

Factors that affect the entropy (pages 877 through 879)

You can sometimes anticipate the sign of the entropy change for a system because certain factors favor an increase in entropy.

- *Volume*: Entropy increases with increasing volume.
- *Temperature*: Entropy increases with increasing temperature.
- *Physical state*: $S_{\text{gas}} \gg S_{\text{liquid}} > S_{\text{solid}}$. When gases are formed in a reaction, ΔS is almost always positive.
- *Number of particles*: Entropy increases when the number of particles increases.

Gibbs free energy (page 882)

The Gibbs free energy is defined in terms of ΔH and ΔS by the equation

$$\Delta G = \Delta H - T\Delta S$$

ΔG as a predictor of spontaneity (page 882)

You can use the sign of ΔG to tell whether a particular change is spontaneous.

Standard entropy change (page 884)

Calculate the standard entropy change for a reaction using the following equation and standard entropy values from Table 19.1. The calculation is similar to the Hess's law calculation of ΔH° you learned in Chapter 7.

$$\Delta S^\circ = (\text{sum of } S^\circ \text{ of products}) - (\text{sum of } S^\circ \text{ of reactants})$$

Calculating ΔG° from ΔH° and ΔS° (page 887)

By calculating ΔH° from data in Table 7.2 and ΔS° from data in Table 19.1 you can calculate ΔG° for a reaction. The equation is

$$\Delta G^\circ = \Delta H^\circ - (298.15\ \text{K})\,\Delta S^\circ$$

Calculating ΔG° using ΔG_f° values (page 888)

When you want ΔG° for a reaction, use ΔG_f° data from Table 19.2 and the equation

$$\Delta G^\circ = (\text{sum of } \Delta G_f^\circ \text{ of products}) - (\text{sum of } \Delta G_f^\circ \text{ of reactants})$$

Using ΔG° to assess the position of equilibrium (page 897)

The sign and magnitude can serve as a qualitative indicator of the position of equilibrium and lets us anticipate whether an observable amount of product will be formed in a reaction.

- ΔG° is large and positive: position of equilibrium is close to reactants.
- ΔG° is large and negative: position of equilibrium is close to products.
- $\Delta G^\circ = 0$: position of equilibrium lies about midway between reactants and products.

Calculating $\Delta G°$ at temperatures other than 25 °C (page 898)

When you need $\Delta G°$ at some temperature other than 25 °C, assume $\Delta H°$ and $\Delta S°$ are nearly independent of temperature and use the equation

$$\Delta G_T^\circ \approx \Delta H_{298}^\circ - T\Delta S_{298}^\circ$$

Such a calculation would be needed to estimate an equilibrium constant at a temperature other than 25 °C.

Relating the reaction quotient to ΔG (page 900)

We can tell whether a particular reaction mixture composition will lead to a spontaneous reaction in the forward direction, the reverse direction, or whether the reaction is at equilibrium by calculating ΔG by the equation

$$\Delta G = \Delta G° + RT \ln Q$$

- If ΔG is negative, the reaction is spontaneous in the forward direction.
- If ΔG is positive, the reaction is spontaneous in the reverse direction.
- If ΔG is zero, the reaction is at equilibrium.

Determining thermodynamic equilibrium constants (page 902)

The following important equation lets us calculate equilibrium constants from thermodynamic data, or calculate $\Delta G°$ from measured equilibrium constants.

$$\Delta G° = -RT \ln K$$

Remember to use $R = 8.314 \text{ J mol}^{-1} \text{ K}^{-1}$, T in kelvins, and that $K = K_P$ for gaseous reactions and K_c for reactions in solution.

PLUS = *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com.** **ILW** = An Interactive Learningware solution is available for this problem. **OH** = An Office Hour video is available for this problem. Review Problems are presented in pairs separated by blue rules. Answers to problems whose numbers appear in blue are given in Appendix B. More challenging problems are marked with an asterisk *.

Review Questions

First Law of Thermodynamics

19.1 What is the origin of the name *thermodynamics*?

19.2 State the first law of thermodynamics in words. What equation defines the change in the internal energy in terms of heat and work? Define the meaning of the symbols, including the significance of their algebraic signs.

19.3 How is a change in the internal energy defined in terms of the initial and final internal energies?

19.4 What is the algebraic sign of ΔE for an endothermic change? Why?

19.5 Which quantities in the statement of the first law are state functions and which are not?

19.6 Which thermodynamic quantity corresponds to the heat at constant volume? Which corresponds to the heat at constant pressure?

19.7 What are the units of $P\Delta V$ if pressure is expressed in pascals and volume is expressed in cubic meters?

19.8 If there is a decrease in the number of moles of gas during an exothermic chemical reaction, which is numerically larger, ΔE or ΔH? Why?

19.9 Which of the following changes is accompanied by the most negative value of ΔE? (a) A spring is compressed and heated. (b) A compressed spring expands and is cooled. (c) A spring is compressed and cooled. (d) A compressed spring expands and is heated.

Spontaneous Change

19.10 What is a *spontaneous change*? What role does kinetics play in determining the apparent spontaneity of a chemical reaction?

19.11 List five changes that you have encountered recently that occurred spontaneously. List five changes that are nonspontaneous that you have caused to occur.

19.12 Which of the items that you listed in Question 19.11 are exothermic (leading to a lowering of the potential energy) and which are endothermic (accompanied by an increase in potential energy)?

19.13 At constant pressure, what role does the enthalpy change play in determining the spontaneity of an event?

19.14 How do the probabilities of the initial and final states in a process affect the spontaneity of the process?

Entropy

19.15 An instant cold pack purchased in a pharmacy contains a packet of solid ammonium nitrate surrounded by a pouch of water. When the packet of NH_4NO_3 is broken, the solid dissolves in water and a cooling of the mixture occurs because the solution process for NH_4NO_3 in water is endothermic. Explain, in terms of what happens to the molecules and ions, why this mixing occurs spontaneously.

19.16 What is *entropy*?

19.17 How is the entropy of a substance affected by (a) an increase in temperature, (b) a decrease in volume, (c) changing from a liquid to a solid, and (d) dissociating into individual atoms?

19.18 Will the entropy change for each of the following be positive or negative?

(a) Moisture condenses on the outside of a cold glass.

(b) Raindrops form in a cloud.

(c) Gasoline vaporizes in the carburetor of an automobile engine.

(d) Air is pumped into a tire.

(e) Frost forms on the windshield of your car.

(f) Sugar dissolves in coffee.

19.19 On the basis of our definition of entropy, suggest why entropy is a state function.

19.20 State the second law of thermodynamics.

19.21 How can a process have a negative entropy change for the system, and yet still be spontaneous?

Third Law of Thermodynamics and Standard Entropies

19.22 What is the third law of thermodynamics?

19.23 Would you expect the entropy of an alloy (a solution of two metals) to be zero at 0 K? Explain your answer.

19.24 Why does entropy increase with increasing temperature?

19.25 Does glass have $S = 0$ at 0 K? Explain.

Standard (Gibbs) Free Energy Change, $\Delta G°$

19.26 What is the equation expressing the change in the Gibbs free energy for a reaction occurring at constant temperature and pressure?

19.27 In terms of the algebraic signs of ΔH and ΔS, under which of the following circumstances will a change be spontaneous:

(a) At all temperatures?

(b) At low temperatures but not at high temperatures?

(c) At high temperatures but not at low temperatures?

19.28 Under what circumstances will a change be nonspontaneous regardless of the temperature?

Maximum Work and ΔG

19.29 How is free energy related to useful work?

19.30 What is a thermodynamically reversible process? How is the amount of work obtained from a change related to thermodynamic reversibility?

19.31 How is the *rate* at which energy is withdrawn from a system related to the amount of that energy that can appear as useful work?

19.32 When glucose is oxidized by the body to generate energy, part of the energy is used to make molecules of ATP (adenosine triphosphate). However, of the total energy released in the oxidation of glucose, only 38% actually goes to making ATP. What happens to the rest of the energy?

19.33 Why are real, observable changes not considered to be thermodynamically reversible processes?

Free Energy and Equilibrium

19.34 In what way is free energy related to equilibrium?

19.35 Considering the fact that the formation of a bond between two atoms is exothermic and is accompanied by an entropy decrease, explain why all chemical compounds decompose into individual atoms if heated to a high enough temperature.

19.36 When a warm object is placed in contact with a cold one, they both gradually come to the same temperature. On a molecular level, explain how this is related to entropy and spontaneity.

19.37 Sketch the shape of the free energy curve for a chemical reaction that has a positive $\Delta G°$. Indicate the composition of the reaction mixture corresponding to equilibrium.

19.38 Many reactions that have large, negative values of $\Delta G°$ are not actually observed to happen at 25 °C and 1 atm. Why?

Standard Free Energy and Equilibrium Constants

19.39 Suppose a reaction has a negative $\Delta H°$ and a negative $\Delta S°$. Will more or less product be present at equilibrium as the temperature is raised?

19.40 Write the equation that relates the free energy change to the value of the reaction quotient for a reaction.

19.41 How is the equilibrium constant related to the standard free energy change for a reaction? (Write the equation.)

19.42 What is the value of $\Delta G°$ for a reaction for which $K = 1$?

Bond Energies and Heats of Reaction

19.43 Define the term atomization energy.

19.44 Why are the heats of formation of gaseous atoms from their elements endothermic quantities?

19.45 The gaseous C_2 molecule has a bond energy of 602 kJ mol^{-1}. Why isn't the standard heat of formation of $C(g)$ equal to half this value?

Review Problems

First Law of Thermodynamics

19.46 A certain system absorbs 0.300 kJ of heat and has 0.700 kJ of work performed on it. What is the value of ΔE for the change? Is the overall change exothermic or endothermic?

19.47 The value of ΔE for a certain change is -1455 J. During the change, the system absorbs 812 J of heat. Did the system do work, or was work done on the system? How much work, expressed in joules, was involved?

19.48 Suppose that you were pumping an automobile tire with a hand pump that pushed 24.0 in.^{3} of air into the tire on each stroke, and that during one such stroke the opposing pressure in the tire was 30.0 lb/in.^{2} above the normal atmospheric pressure of 14.7 lb/in.^{2}. Calculate the number of joules of work accomplished during each stroke. (1 L atm = 101.325 J)

OH **19.49** Consider the reaction between aqueous solutions of baking soda, $NaHCO_3$, and vinegar, $HC_2H_3O_2$.

$$NaHCO_3(aq) + HC_2H_3O_2(aq) \longrightarrow NaC_2H_3O_2(aq) + H_2O(l) + CO_2(g)$$

If this reaction occurs at 1.00 atmospheres of pressure, how much work, expressed in *L atm*, is done by the system in pushing back the atmosphere when 1.00 mol $NaHCO_3$ reacts at a temperature of 25 °C? (*Hint*: Review the gas laws.)

19.50 Calculate $\Delta H°$ and $\Delta E°$ for the following reactions at 25 °C. (If necessary, refer to the data in Table C.2 in Appendix C.)

(a) $3PbO(s) + 2NH_3(g) \longrightarrow 3Pb(s) + N_2(g) + 3H_2O(g)$

(b) $NaOH(s) + HCl(g) \longrightarrow NaCl(s) + H_2O(l)$

(c) $Al_2O_3(s) + 2Fe(s) \longrightarrow Fe_2O_3(s) + 2Al(s)$

(d) $2CH_4(g) \longrightarrow C_2H_6(g) + H_2(g)$

19.51 Calculate $\Delta H°$ and $\Delta E°$ for the following reactions at 25 °C. (If necessary, refer to the data in Table C.2 in Appendix C.)

(a) $2C_2H_2(g) + 5O_2(g) \longrightarrow 4CO_2(g) + 2H_2O(g)$

(b) $C_2H_2(g) + 5N_2O(g) \longrightarrow 2CO_2(g) + H_2O(g) + 5N_2(g)$

(c) $NH_4Cl(s) \longrightarrow NH_3(g) + HCl(g)$

(d) $(CH_3)_2CO(l) + 4O_2(g) \longrightarrow 3CO_2(g) + 3H_2O(g)$

19.52 The reaction

$$2N_2O(g) \longrightarrow 2N_2(g) + O_2(g)$$

has $\Delta H° = -163.14$ kJ. What is the value of ΔE for the decomposition of 186 g of N_2O at 25 °C? If we assume that ΔH doesn't change appreciably with temperature, what is ΔE for this same reaction at 217 °C?

19.53 A 10.0 L vessel at 22 °C contains butane, $C_4H_{10}(g)$, at a pressure of 2.00 atm. What is the maximum amount of work that can be obtained by the combustion of this butane if the gas is first brought to a pressure of 1 atm and the temperature is brought to 28 °C? Assume the products are also returned to this same temperature and pressure.

Spontaneous Chemical and Physical Change

19.54 Use the data from Table 7.2 to calculate $\Delta H°$ for the following reactions. On the basis of their values of $\Delta H°$, which are favored to occur spontaneously?

(a) $CaO(s) + CO_2(g) \longrightarrow CaCO_3(s)$

(b) $C_2H_2(g) + 2H_2(g) \longrightarrow C_2H_6(g)$

(c) $3CaO(s) + 2Fe(s) \longrightarrow 3Ca(s) + Fe_2O_3(s)$

19.55 Use the data from Table 7.2 to calculate $\Delta H°$ for the following reactions. On the basis of their values of $\Delta H°$, which are favored to occur spontaneously?

(a) $NH_4Cl(s) \longrightarrow NH_3(g) + HCl(g)$

(b) $2C_2H_2(g) + 5O_2(g) \longrightarrow 4CO_2(g) + 2H_2O(g)$

(c) $C_2H_2(g) + 5N_2O(g) \longrightarrow 2CO_2(g) + H_2O(g) + 5N_2(g)$

19.56 What factors must you consider to determine the sign of ΔS for the reaction $2N_2O(g) \longrightarrow 2N_2(g) + O_2(g)$ if it occurs at constant temperature?

19.57 What factors must you consider to determine the sign of ΔS for the reaction: $2HI(g) \longrightarrow H_2(g) + I_2(s)$?

19.58 Predict the algebraic sign of the entropy change for the following reactions.

(a) $PCl_3(g) + Cl_2(g) \longrightarrow PCl_5(g)$

(b) $SO_2(g) + CaO(s) \longrightarrow CaSO_3(s)$

(c) $CO_2(g) + H_2O(l) \longrightarrow H_2CO_3(aq)$

(d) $Ni(s) + 2HCl(aq) \longrightarrow H_2(g) + NiCl_2(aq)$

OH **19.59** Predict the algebraic sign of the entropy change for the following reactions.

(a) $I_2(s) \longrightarrow I_2(g)$

(b) $Br_2(g) + 3Cl_2(g) \longrightarrow 2BrCl_3(g)$

(c) $NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$

(d) $CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(s)$

Third Law of Thermodynamics

19.60 Calculate $\Delta S°$ for the following reactions in J K^{-1} from the data in Table 19.1. On the basis of their values of $\Delta S°$, which of these reactions are favored to occur spontaneously?

(a) $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$

(b) $CO(g) + 2H_2(g) \longrightarrow CH_3OH(l)$

(c) $2C_2H_6(g) + 7O_2(g) \longrightarrow 4CO_2(g) + 6H_2O(g)$

(d) $Ca(OH)_2(s) + H_2SO_4(l) \longrightarrow CaSO_4(s) + 2H_2O(l)$

(e) $S(s) + 2N_2O(g) \longrightarrow SO_2(g) + 2N_2(g)$

19.61 Calculate $\Delta S°$ for the following reactions in $J\ K^{-1}$, using the data in Table 19.1.

(a) $Ag(s) + \frac{1}{2}Cl_2(g) \longrightarrow AgCl(s)$

(b) $H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(g)$

(c) $H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l)$

(d) $CaCO_3(s) + H_2SO_4(l) \longrightarrow CaSO_4(s) + H_2O(g) + CO_2(g)$

(e) $NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$

OH **19.62** Calculate $\Delta S_f°$ for the following compounds in $J\ mol^{-1}\ K^{-1}$.

(a) $C_2H_4(g)$

(b) $HC_2H_3O_2(l)$

(c) $CaSO_4 \cdot 2H_2O(s)$

19.63 Calculate $\Delta S_f°$ for the following compounds in $J\ mol^{-1}\ K^{-1}$.

(a) $Al_2O_3(s)$

(b) $CaSO_4 \cdot \frac{1}{2}H_2O(s)$

(c) $NH_4Cl(s)$

19.64 Nitrogen dioxide, NO_2, an air pollutant, dissolves in rainwater to form a dilute solution of nitric acid. The equation for the reaction is

$$3NO_2(g) + H_2O(l) \longrightarrow 2HNO_3(l) + NO(g)$$

Calculate $\Delta S°$ for this reaction in $J\ K^{-1}$.

19.65 Good wine will turn to vinegar if it is left exposed to air, because the alcohol is oxidized to acetic acid. The equation for the reaction is

$$C_2H_5OH(l) + O_2(g) \longrightarrow HC_2H_3O_2(l) + H_2O(l)$$

Calculate $\Delta S°$ for this reaction in $J\ K^{-1}$.

Standard (Gibbs) Free Energy

ILW **19.66** Phosgene, $COCl_2$, was used as a war gas during World War I. It reacts with the moisture in the lungs to produce HCl, which causes the lungs to fill with fluid, and CO, which asphyxiates the victim. Both lead ultimately to death. For $COCl_2(g)$, $S° = 284$ J/mol K and $\Delta H_f° = -223$ kJ/mol. Use this information and the data in Table 19.1 to calculate $\Delta G_f°$ for $COCl_2(g)$ in $kJ\ mol^{-1}$.

OH **19.67** Aluminum oxidizes rather easily, but forms a thin protective coating of Al_2O_3 that prevents further oxidation of the aluminum beneath. Use the data for $\Delta H_f°$ (Table 7.2) and $S°$ (Table 19.1) to calculate $\Delta G_f°$ for $Al_2O_3(s)$ in $kJ\ mol^{-1}$.

19.68 Compute $\Delta G°$ in kJ for the following reactions, using the data in Table 19.2.

(a) $SO_3(g) + H_2O(l) \longrightarrow H_2SO_4(l)$

(b) $2NH_4Cl(s) + CaO(s) \longrightarrow CaCl_2(s) + H_2O(l) + 2NH_3(g)$

(c) $CaSO_4(s) + 2HCl(g) \longrightarrow CaCl_2(s) + H_2SO_4(l)$

19.69 Compute $\Delta G°$ in kJ for the following reactions, using the data in Table 19.2.

(a) $2HCl(g) + CaO(s) \longrightarrow CaCl_2(s) + H_2O(g)$

(b) $2AgCl(s) + Ca(s) \longrightarrow CaCl_2(s) + 2Ag(s)$

(c) $3NO_2(g) + H_2O(l) \longrightarrow 2HNO_3(l) + NO(g)$

*__19.70__ Given the following,

$$4NO(g) \longrightarrow 2N_2O(g) + O_2(g) \qquad \Delta G° = -139.56\ kJ$$

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g) \qquad \Delta G° = -69.70\ kJ$$

calculate $\Delta G°$ for the reaction

$$2N_2O(g) + 3O_2(g) \longrightarrow 4NO_2(g)$$

*__19.71__ Given the following reactions and their $\Delta G°$ values,

$$COCl_2(g) + 4NH_3(g) \longrightarrow CO(NH_2)_2(s) + 2NH_4Cl(s) \qquad \Delta G° = -332.0\ kJ$$

$$COCl_2(g) + H_2O(l) \longrightarrow CO_2(g) + 2HCl(g) \qquad \Delta G° = -141.8\ kJ$$

$$NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s) \qquad \Delta G° = -91.96\ kJ$$

Calculate the value of $\Delta G°$ for the reaction

$$CO(NH_2)_2(s) + H_2O(l) \longrightarrow CO_2(g) + 2NH_3(g)$$

Free Energy and Work

OH **19.72** Gasohol is a mixture of gasoline and ethanol (grain alcohol), C_2H_5OH. Calculate the maximum work that could be obtained at 25 °C and 1 atm by burning 1 mol of C_2H_5OH.

$$C_2H_5OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(g)$$

19.73 What is the maximum amount of useful work that could possibly be obtained at 25 °C and 1 atm from the combustion of 48.0 g of natural gas, $CH_4(g)$ to give $CO_2(g)$ and $H_2O(g)$?

Free Energy and Equilibrium

19.74 Chloroform, formerly used as an anesthetic and now believed to be a carcinogen, has a heat of vaporization $\Delta H_{vaporization} = 31.4\ kJ\ mol^{-1}$. The change, $CHCl_3(l) \longrightarrow CHCl_3(g)$, has $\Delta S° = 94.2\ J\ mol^{-1}\ K^{-1}$. At what temperature do we expect $CHCl_3$ to boil (i.e., at what temperature will liquid and vapor be in equilibrium at 1 atm pressure)?

OH **19.75** For the melting of aluminum, $Al(s) \longrightarrow Al(l)$, $\Delta H° = 10.0\ kJ\ mol^{-1}$ and $\Delta S° = 9.50$ J/mol K. Calculate the melting point of Al. (The actual melting point is 660 °C.)

19.76 Isooctane, an important constituent of gasoline, has a boiling point of 99.3 °C and a heat of vaporization of $37.7\ kJ\ mol^{-1}$. What is ΔS (in $J\ mol^{-1}\ K^{-1}$) for the vaporization of 1 mol of isooctane?

19.77 Acetone (nail polish remover) has a boiling point of 56.2 °C. The change, $(CH_3)_2CO(l) \longrightarrow (CH_3)_2CO(g)$, has $\Delta H° = 31.9\ kJ\ mol^{-1}$. What is $\Delta S°$ for this change?

Free Energy and Spontaneity of Chemical Reactions

ILW **19.78** Determine whether the following reaction (equation unbalanced) will be spontaneous at 25 °C. (Do we expect appreciable amounts of products to form?)

$$C_2H_4(g) + HNO_3(l) \longrightarrow HC_2H_3O_2(l) + H_2O(l) + NO(g) + NO_2(g)$$

19.79 Which of the following reactions (equations unbalanced) would be expected to be spontaneous at 25 °C and 1 atm?

(a) $PbO(s) + NH_3(g) \longrightarrow Pb(s) + N_2(g) + H_2O(g)$

(b) $NaOH(s) + HCl(g) \longrightarrow NaCl(s) + H_2O(l)$

(c) $Al_2O_3(s) + Fe(s) \longrightarrow Fe_2O_3(s) + Al(s)$

(d) $2CH_4(g) \longrightarrow C_2H_6(g) + H_2(g)$

Thermodynamic Equilibrium Constants

OH **19.80** Calculate the value of the thermodynamic equilibrium constant for the following reactions at 25 °C. (Refer to the data in Appendix C.2.)

(a) $2PCl_3(g) + O_2(g) \rightleftharpoons 2POCl_3(g)$

(b) $2SO_3(g) \rightleftharpoons 2SO_2(g) + O_2(g)$

19.81 Calculate the value of the thermodynamic equilibrium constant for the following reactions at 25 °C. (Refer to the data in Appendix C.2.)

(a) $N_2H_4(g) + 2O_2(g) \rightleftharpoons 2NO(g) + 2H_2O(g)$

(b) $N_2H_4(g) + 6H_2O_2(g) \rightleftharpoons 2NO_2(g) + 8H_2O(g)$

ILW **19.82** The reaction $NO_2(g) + NO(g) \rightleftharpoons N_2O(g) + O_2(g)$ has $\Delta G^\circ_{1273} = -9.67$ kJ. A 1.00 L reaction vessel at 1000.0 °C contains 0.0200 mol NO_2, 0.040 mol NO, 0.015 mol N_2O, and 0.0350 mol O_2. Is the reaction at equilibrium? If not, in which direction will the reaction proceed to reach equilibrium?

19.83 The reaction $CO(g) + H_2O(g) \rightleftharpoons HCHO_2(g)$ has $\Delta G^\circ_{673} = +79.8$ kJ mol^{-1}. If a mixture at 673 K contains 0.040 mol CO, 0.022 mol H_2O, and 3.8×10^{-3} mol $HCHO_2$ in a 2.50 L container, is the reaction at equilibrium? If not, in which direction will the reaction proceed spontaneously?

19.84 A reaction that can convert coal to methane (the chief component of natural gas) is

$$C(s) + 2H_2(g) \rightleftharpoons CH_4(g)$$

for which $\Delta G^\circ = -50.79$ kJ mol^{-1}. What is the value of K_p for this reaction at 25 °C? Does this value of K_p suggest that studying this reaction as a means of methane production is worthwhile pursuing?

***19.85** One of the important reactions in living cells from which the organism draws energy is the reaction of adenosine triphosphate (ATP) with water to give adenosine diphosphate (ADP) and free phosphate ion.

$$ATP + H_2O \rightleftharpoons ADP + PO_4^{3-}$$

The value of ΔG°_{310} for this reaction at 37 °C (normal human body temperature) is -33 kJ mol^{-1}. Calculate the value of the equilibrium constant for the reaction at this temperature.

19.86 What is the value of the equilibrium constant for a reaction for which $\Delta G^\circ = 0$? What will happen to the composition of the system if we begin the reaction with the pure products?

19.87 Methanol, a potential replacement for gasoline as an automotive fuel, can be made from H_2 and CO by the reaction

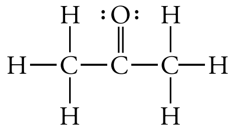
$$CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$$

At 500.0 K, this reaction has $K_p = 6.25 \times 10^{-3}$. Calculate ΔG°_{500} for this reaction in units of kilojoules.

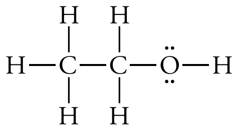
Bond Energies

19.88 Use the data in Table 19.4 to compute the approximate atomization energy of NH_3.

19.89 Approximately how much energy would be released during the formation of the bonds in one mole of acetone molecules? Acetone, the solvent usually found in nail polish remover, has the structural formula



OH **19.90** The standard heat of formation of ethanol vapor, $C_2H_5OH(g)$, is -235.3 kJ mol^{-1}. Use the data in Table 19.3 and the average bond energies for C—C, C—H, and O—H bonds to estimate the C—O bond energy in this molecule. The structure of the molecule is



19.91 The standard heat of formation of ethylene, $C_2H_4(g)$, is $+52.284$ kJ mol^{-1}. Calculate the C═C bond energy in this molecule.

ILW **19.92** Carbon disulfide, CS_2, has the Lewis structure $:\ddot{S}{=}C{=}\ddot{S}:$, and for $CS_2(g)$, $\Delta H^\circ_f = +115.3$ kJ mol^{-1}. Use the data in Table 19.3 to calculate the average C═S bond energy in this molecule.

19.93 Gaseous hydrogen sulfide, H_2S, has $\Delta H^\circ_f = -20.15$ kJ mol^{-1}. Use the data in Table 19.3 to calculate the average S—H bond energy in this molecule.

19.94 For $SF_6(g)$, $\Delta H^\circ_f = -1096$ kJ mol^{-1}. Use the data in Table 19.3 to calculate the average S—F bond energy in SF_6.

19.95 Use the results of the preceding problem and the data in Table C.3 of Appendix C to calculate the standard heat of formation of $SF_4(g)$. The measured value of ΔH_f° for $SF_4(g)$ is -718.4 kJ mol^{-1}. What is the percentage difference between your calculated value of ΔH_f° and the experimentally determined value?

19.96 Use the data in Tables 19.3 and 19.4 to estimate the standard heat of formation of acetylene, $H{-}C{\equiv}C{-}H$, in the gaseous state.

19.97 What would be the approximate heat of formation of CCl_4 vapor at 25 °C and 1 atm?

19.98 Which substance should have the more exothermic heat of formation, CF_4 or CCl_4?

***19.99** Would you expect the value of ΔH_f° for benzene, C_6H_6, computed from tabulated bond energies, to be very close to the experimentally measured value of ΔH_f°? Justify your answer.

Additional Exercises

19.100 If pressure is expressed in atmospheres and volume is expressed in liters, $P\,\Delta V$ has units of L atm (liters × atmospheres). In Chapter 11 you learned that 1 atm = 101,325 Pa, and in Chapter 2 you learned that 1 L = 1 dm^3. Use this information to determine the number of joules corresponding to 1 L atm.

19.101 Calculate the work, in joules, done by a gas as it expands at constant temperature from a volume of 3.00 L and a pressure of 5.00 atm to a volume of 8.00 L. The external pressure against which the gas expands is 1.00 atm. (1 atm = 101,325 Pa)

***19.102** When an ideal gas expands at a constant temperature, $\Delta E = 0$ for the change. Why?

***19.103** When a real gas expands at a constant temperature, $\Delta E > 0$ for the change. Why?

19.104 An ideal gas in a cylinder fitted with a piston expands at constant temperature from a pressure of 5 atm and a volume of 6.0 L to a final volume of 12 L against a constant opposing pressure of 2.5 atm. How much heat does the gas absorb, expressed in units of L atm (liter × atm)? (*Hint*: See Exercise 19.102.)

***19.105** A cylinder fitted with a piston contains 5.00 L of a gas at a pressure of 4.00 atm. The entire apparatus is contained in a water bath to maintain a constant temperature of 25 °C. The piston is released and the gas expands until the pressure inside the cylinder equals the atmospheric pressure outside, which is 1 atm. Assume ideal gas behavior and calculate the amount of work done by the gas as it expands at constant temperature.

***19.106** The experiment described in Exercise 19.105 is repeated, but this time a weight, which exerts a pressure of 2 atm, is placed on the piston. When the gas expands, its pressure drops to this 2 atm pressure. Then the weight is removed and the gas is allowed to expand again to a final pressure of 1 atm. Throughout both expansions the temperature of the apparatus was held at a constant 25 °C. Calculate the amount of work performed by the gas in each step. How does the combined total amount of work in this two-step expansion compare with the amount of work done by the gas in the one-step expansion described in Exercise 19.105? How can even more work be obtained by the expansion of the gas?

19.107 When potassium iodide dissolves in water, the mixture becomes cool. For this change, which is of a larger magnitude, $T\,\Delta S$ or ΔH?

19.108 The enthalpy of combustion, $\Delta H^\circ_{\text{combustion}}$, of oxalic acid, $H_2C_2O_4(s)$, is -246.05 kJ mol^{-1}. Consider the following data:

Substance	ΔH_f° (kJ mol^{-1})	S° (J mol^{-1} K^{-1})
$C(s)$	0	5.69
$CO_2(g)$	-393.5	213.6
$H_2(g)$	0	130.6
$H_2O(l)$	-285.8	69.96
$O_2(g)$	0	205.0
$H_2C_2O_4(s)$	?	120.1

(a) Write the balanced thermochemical equation that describes the combustion of one mole of oxalic acid.

(b) Write the balanced thermochemical equation that describes the formation of one mole of oxalic acid.

(c) Use the information in the table above and the equations in parts (a) and (b) to calculate ΔH_f° for oxalic acid.

(d) Calculate ΔS_f° for oxalic acid and ΔS° for the combustion of one mole of oxalic acid.

(e) Calculate ΔG_f° for oxalic acid and ΔG° for the combustion of one mole of oxalic acid.

OH **19.109** Many biochemical reactions have positive values for ΔG° and seemingly should not be expected to be spontaneous. They occur, however, because they are chemically coupled with other reactions that have negative values of ΔG°. An example is the set of reactions that forms the beginning part of the sequence of reactions involved in the metabolism of glucose, a sugar. Given these reactions and their corresponding ΔG° values,

$$\text{glucose} + \text{phosphate} \longrightarrow \text{glucose 6-phosphate} + H_2O \qquad \Delta G^\circ = +13.13 \text{ kJ}$$

$$\text{ATP} + H_2O \longrightarrow \text{ADP} + \text{phosphate} \qquad \Delta G^\circ = -32.22 \text{ kJ}$$

calculate ΔG° for the coupled reaction

$$\text{glucose} + \text{ATP} \longrightarrow \text{glucose 6-phosphate} + \text{ADP}$$

*19.110 The reaction

$$2C_4H_{10}(g) + 13O_2(g) \longrightarrow 8CO_2(g) + 10H_2O(g)$$

has $\Delta G^\circ = -5407$ kJ. Determine the value of ΔG°_f for $C_4H_{10}(g)$. Calculate the value of K_c for the reaction at 25 °C.

*19.111 At 1500 °C, $K_c = 5.67$ for the reaction

$$CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g)$$

Calculate the value of ΔG°_{1773} for the reaction at this temperature.

19.112 Given the following reactions and their values of ΔG°, calculate the value of ΔG°_f for $N_2O_5(g)$.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l) \qquad \Delta G^\circ = -474.4 \text{ kJ}$$

$$N_2O_5(g) + H_2O(l) \longrightarrow 2HNO_3(l) \qquad \Delta G^\circ = -37.6 \text{ kJ}$$

$$\tfrac{1}{2}N_2(g) + \tfrac{1}{2}O_2(g) + \tfrac{1}{2}H_2(g) \longrightarrow HNO_3(l) \qquad \Delta G^\circ = -79.91 \text{ kJ}$$

*19.113 At room temperature (25 °C), the gas ClNO is impure because it decomposes slightly according to the equation

$$2ClNO(g) \rightleftharpoons Cl_2(g) + 2NO(g)$$

The extent of decomposition is about 5%. What is the approximate value of ΔG°_{298} for this reaction at this temperature?

*19.114 The reaction

$$N_2O(g) + O_2(g) \rightleftharpoons NO_2(g) + NO(g)$$

has $\Delta H^\circ = -42.9$ kJ and $\Delta S^\circ = -26.1$ J/K. Suppose 0.100 mol of N_2O and 0.100 mol of O_2 are placed in a 2.00 L container at 475 °C and this equilibrium is established. What percentage of the N_2O has reacted? (*Note:* Assume that ΔH and ΔS are relatively insensitive to temperature, so ΔH°_{298} and ΔS°_{298} are about the same as ΔH°_{773} and ΔS°_{773}, respectively.)

19.115 Use the data in Table 19.3 to calculate the bond energy in the nitrogen molecule and the oxygen molecule.

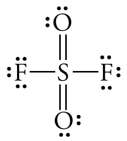
19.116 The heat of vaporization of carbon tetrachloride, CCl_4, is 29.9 kJ mol^{-1}. Using this information and data in Tables 19.3 and 19.4, estimate the standard heat of formation of liquid CCl_4.

19.117 At 25 °C, 0.0560 mol O_2 and 0.020 mol N_2O were placed in a 1.00 L container where the following equilibrium was then established.

$$2N_2O(g) + 3O_2(g) \rightleftharpoons 4NO_2(g)$$

At equilibrium, the NO_2 concentration was 0.020 *M*. Calculate the value of ΔG° for the reaction.

19.118 For the substance $SO_2F_2(g)$, $\Delta H^\circ_f = -858$ kJ mol^{-1}. The structure of the SO_2F_2 molecule is



Use the value of the S—F bond energy calculated in Problem 19.94 and the data in Appendix C.3 to determine the average S═O bond energy in SO_2F_2 in units of kJ mol^{-1}.

Multi-Concept Questions

*19.119 Ethyl alcohol, C_2H_5OH, has been suggested as an alternative to gasoline as a fuel. In Example 19.5 we calculated ΔG° for combustion of 1 mol of C_2H_5OH; in Example 19.6 we calculated ΔG° for combustion of 1 mol of octane. Let's assume that gasoline has the same properties as octane (one of its constituents). The density of C_2H_5OH is 0.7893 g/mL; the density of octane, C_8H_{18}, is 0.7025 g/mL. Calculate the maximum work that could be obtained by burning 1 gallon (3.78 liters) each of C_2H_5OH and C_8H_{18}. On a *volume* basis, which is the better fuel?

*19.120 When solutions of sodium hydroxide are used to neutralize hydrochloric acid, the standard heat of reaction is found to be −55.86 kJ. When propionic acid $HC_3H_5O_2$ is neutralized with sodium hydroxide the standard heat of the reaction is −49.23 kJ. What is the standard heat and entropy change for the ionization of propionic acid?

*19.121 You've recently inherited a fortune and immediately after that an inventor approaches you with the investment deal of a lifetime. The inventor has found a "system" to react water with methane to make methanol and hydrogen gas, two potentially valuable fuels. In your interview with the inventor, it is claimed that a revolutionary new catalyst shifts the equilibrium position of the reaction to favor products and that 134 kg of methanol are produced for each 117 cubic meters of methane used (at STP). Use your knowledge of chemical principles to find all of the flaws in this project before deciding to risk your new fortune on it.

***19.122** A certain weak acid has a pK_a of 5.83. When 100.0 mL of a 0.00525 M solution of this weak acid at 21.26 °C is reacted with 45.6 mL of 0.00634 M sodium hydroxide ($HA + OH^- \longrightarrow A^- + H_2O$) at 22.18 °C, the temperature of the mixture rises to 24.88 °C. What is the entropy change associated with the ionization ($HA \longrightarrow A^- + H^+$) of this weak acid? (Assume that the volumes are additive and the densities of the two solutions are 1.000 g cm^{-3}, with a specific heat that is the same as pure water.)

Exercises in Critical Thinking

19.123 On earth, we do not normally find collections of individual subatomic particles, such as protons, neutrons, and electrons. Rather, they are assembled into atoms of various kinds. On the other hand, in the interior of stars individual atoms don't exist. There, an atom would break apart into separate subatomic particles. Explain this in terms of the principles of thermodynamics.

19.124 The average C—H bond energy calculated using the procedure in Section 19.10 is not quite equal to the energy needed to cause the reaction $CH_4(g) \longrightarrow CH_3(g) + H(g)$. Suggest reasons why this is so.

19.125 Discuss this statement: A world near absolute zero would be controlled almost entirely by potential energy. NASA states that the average temperature of the universe is 2.73 K. What does this mean about the universe?

19.126 If a catalyst were able to affect the position of equilibrium in a reaction, it would be possible to construct a perpetual motion machine (a machine from which energy could be extracted without having to put energy into it). Imagine how such a machine could be made. Why would it violate the first law of thermodynamics?

19.127 At the beginning of this chapter we noted that the reaction of CO_2 with H_2O to form a hydrocarbon fuel is nonspontaneous. According to thermodynamics, where would the position of equilibrium lie for such a reaction. Why?

Chapter Outline

20.1 | Galvanic (Voltaic) Cells

20.2 | Cell Potentials

20.3 | Standard Reduction Potentials

20.4 | E°_{cell} and ΔG°

20.5 | Cell Potentials and Concentrations

20.6 | Electricity

20.7 | Electrolytic Cells

20.8 | Electrolysis Stoichiometry

20.9 | Practical Applications of Electrolysis

Governments around the world are coming to the conclusion that we must develop "green" economic and consumption policies that are sustainable far into the future. This means that the use of resources should be minimized, and those resources that are used for a wide variety of human activities must be replenished rapidly. One way to achieve a sustainable energy economy is to convert solar and wind energy directly into electricity, bypassing petroleum and all of its production, refining, and pollution problems. The smart car shown in this photo can utilize green energy sources with a minimum impact on nonrenewable resources. age fotostock/SuperStock

This Chapter in Context

Oxidation and reduction (redox) reactions occur in many chemical systems. Examples include our own respiratory system and the complementary photosynthetic system in plants. In addition there's the toasting of bread, the rusting of iron, the action of bleach on stains, and the production and combustion of petroleum that heats us, generates electricity, and moves our cars. In this chapter we will study how it is possible to separate the processes of oxidation (electron loss) and reduction (electron gain) and cause them to occur in different physical locations. When we are able to do this, we can use spontaneous redox reactions to produce electricity. And by reversing the process, we can use electricity to make nonspontaneous redox reactions happen to produce important products by a process called *electrolysis.*

Because electricity plays a role in these systems, the processes involved are described as **electrochemical changes**. The study of such changes is called **electrochemistry**. As you will learn, electrical measurements and the principles of thermodynamics combine to give fundamental information about chemical reactions, such as free energy changes and equilibrium constants.

The last section of this chapter describes modern batteries. Solar and wind energy are generally thought to be environmentally benign methods for generating electricity. Development of new, highly efficient, light, and relatively inexpensive batteries and fuel cells is an area of intensive research so that solar and wind power can become important contributors to fuel conservation efforts.

20.1 | Galvanic (Voltaic) Cells

Batteries have become common sources of portable power for a wide range of consumer products, from cell phones to iPods to laptops and hybrid cars. The energy from a battery comes from a spontaneous redox reaction in which the electron transfer is forced to take place through a wire. The apparatus that provides electricity in this way is called a **galvanic cell**, after Luigi Galvani (1737–1798), an Italian anatomist who discovered that electricity can cause the contraction of muscles. (It is also called a **voltaic cell**, after another Italian scientist Allesandro Volta (1745–1827), whose inventions led ultimately to the development of modern batteries.)

Construction of a Galvanic Cell

If a shiny piece of metallic copper is placed into an aqueous solution of silver nitrate, a spontaneous reaction occurs. Gradually, a grayish white deposit forms on the copper and the liquid itself becomes pale blue as hydrated Cu^{2+} ions enter the solution (see Figure 20.1). The equation for this reaction is

$$2Ag^+(aq) + Cu(s) \longrightarrow Cu^{2+}(aq) + 2Ag(s)$$

Although the reaction is exothermic, no usable energy can be harnessed from it because all the energy is dispersed as heat.

To produce useful *electrical* energy, the two half-reactions involved in the net reaction must be made to occur in separate containers or compartments called **half-cells.** When this is done, electrons must flow through an external circuit to power devices such as a laser pointer, a laptop computer, or your iPod. An apparatus to accomplish this—a **galvanic**

■ A galvanic cell is composed to two half-cells connected by an external circuit and a salt bridge.

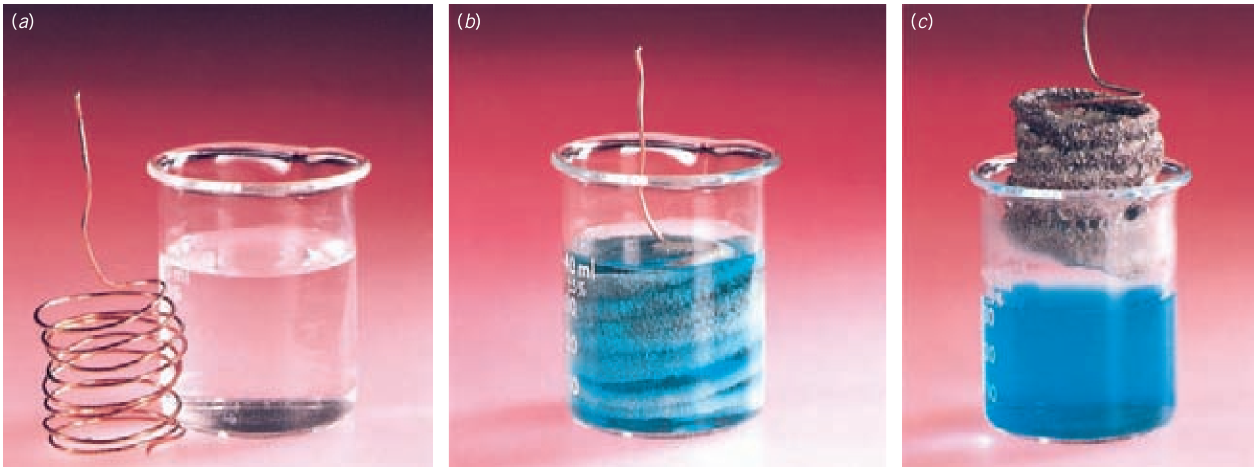

Figure 20.1 | **Reaction of copper with a solution of silver nitrate.** (*a*) A coil of copper wire stands next to a beaker containing a silver nitrate solution. (*b*) When the copper wire is placed in the solution, copper dissolves, giving the solution its blue color, and metallic silver deposits as glittering crystals on the wire. (*c*) After a while, much of the copper has dissolved and nearly all of the silver has deposited as the free metal. *(Michael Watson)*

cell—is made up of two half-cells, as illustrated in Figure 20.2. On the left, a silver electrode dips into a solution of $AgNO_3$, and, on the right, a copper electrode dips into a solution of $Cu(NO_3)_2$. The two electrodes are connected by an external electrical circuit and the two solutions are connected by a *salt bridge*, the function of which will be described shortly. When the circuit is completed by closing the switch, the reduction of Ag^+ to Ag occurs spontaneously in the half-cell on the left and oxidation of Cu to Cu^{2+} occurs spontaneously in the half-cell on the right. The reaction that takes place in each half-cell is a *half-reaction* of the type you learned to balance by the ion-electron method in Chapter 6. In the silver half-cell, the following half-reaction occurs.

$$Ag^+(aq) + e^- \longrightarrow Ag(s) \qquad \text{(reduction)}$$

In the copper half-cell, the half-reaction is

$$Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^- \qquad \text{(oxidation)}$$

When these reactions take place, electrons left behind by oxidation of the copper travel through the external circuit to the other electrode where they are transferred to the silver ions, as Ag^+ is reduced to the familiar shiny silver metal.

NO_3^-

Figure 20.2 | **A galvanic cell.** The cell consists of two half-cells. Oxidation takes place in one half-cell and reduction in the other as indicated by the half-reactions.

Cell Reactions

The overall reaction that takes place in the galvanic cell is called the **cell reaction**. To obtain it, we combine the individual electrode half-reactions, making sure that the number of electrons gained in one half-reaction equals the number lost in the other. Thus, to obtain the cell reaction we multiply the half-reaction for the reduction of silver by 2 and then add the two half-reactions to obtain the net reaction. (Notice that $2e^-$ appears on each side, and so they cancel.) This is exactly the same process we used to balance redox reactions by the ion–electron method described in Section 6.2.

■ When electrons appear as a reactant, the process is reduction; when they appear as a product, it is oxidation.

■ The two electrons canceled in this reaction are also the number of electrons transferred. These will be important later when we discuss the Nernst equation.

$$\begin{array}{rclr} 2\text{Ag}^+(aq) + 2e^- & \longrightarrow & 2\text{Ag}(s) & \text{(reduction)} \\ \text{Cu}(s) & \longrightarrow & \text{Cu}^{2+}(aq) + 2e^- & \text{(oxidation)} \\ \hline 2\text{Ag}^+(aq) + \text{Cu}(s) + \cancel{2e^-} & \longrightarrow & 2\text{Ag}(s) + \text{Cu}^{2+}(aq) + \cancel{2e^-} & \text{(cell reaction)} \end{array}$$

Naming Electrodes in a Galvanic Cell

The electrodes in electrochemical systems are identified by the names *cathode* and *anode*. The names are *always* assigned according to the nature of the chemical changes that occur at the electrodes. In *all electrochemical systems:*

> The **cathode** is the electrode at which reduction (electron gain) occurs.
>
> The **anode** is the electrode at which oxidation (electron loss) occurs.

TOOLS

Electrode names and reactions

Thus, in the galvanic cell we've been discussing, the silver electrode is the cathode and the copper electrode is the anode.

Conduction of Charge

In the external circuit of a galvanic cell, electrical charge is transported from one electrode to the other by the movement of *electrons* through the wires. This is called **metallic conduction,** and it is how metals in general conduct electricity. In this external circuit, electrons always travel from the anode, where they are a product of the oxidation process, to the cathode, where they are picked up by the substance being reduced.

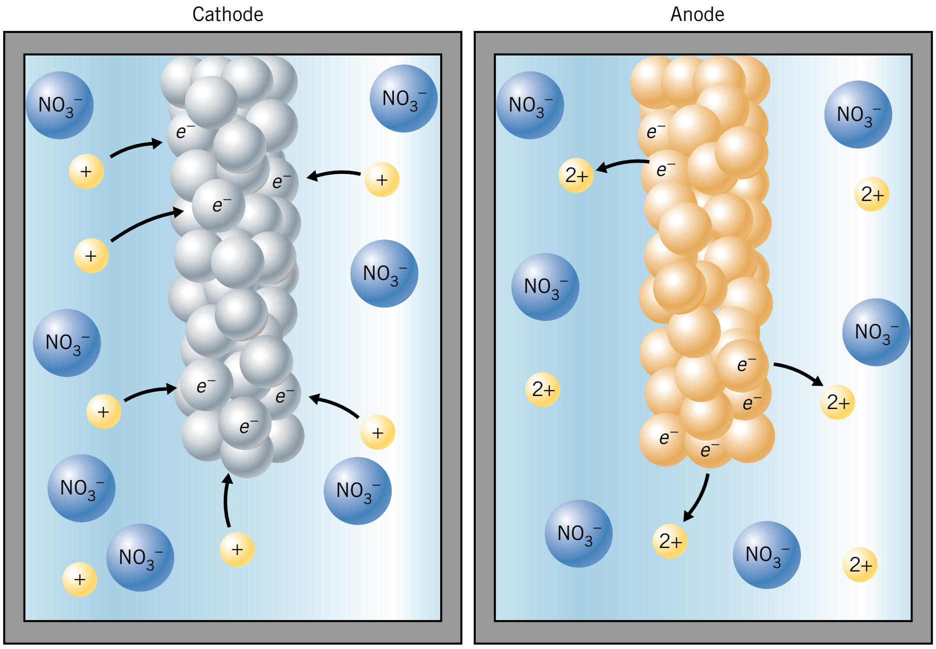
In electrochemical cells another kind of electrical conduction also takes place. In a solution that contains ions (or in a molten ionic compound), *electrical charge is carried through the liquid by the movement of ions, not electrons*. The transport of electrical charge by ions is called **electrolytic conduction.**

When the reactions take place in the copper–silver galvanic cell, positive copper ions *enter* the liquid that surrounds the anode while positive silver ions *leave* the liquid that surrounds the cathode (Figure 20.3). For the galvanic cell to work, the solutions in both half-cells must remain electrically neutral. This requires that ions be permitted to enter or leave the solutions. For example, when copper is oxidized, the solution surrounding the anode becomes filled with Cu^{2+} ions, so negative ions are needed to balance their charge. Similarly, when Ag^+ ions are reduced, $\text{NO}_3{}^-$ ions are left behind in the solution and positive ions are needed to maintain neutrality. The **salt bridge** shown in Figure 20.2 allows the movement of ions required to keep the solutions electrically neutral. The salt bridge is also essential to complete the electrical circuit.

A salt bridge is a tube filled with a solution of a salt composed of ions not involved in the cell reaction. Often KNO_3 or KCl is used. The tube is fitted with porous plugs at each end that prevent the solution from pouring out, but at the same time enabling the solution in the salt bridge to exchange ions with the solutions in the half-cells.

During operation of the cell, negative ions can diffuse from the salt bridge into the copper half-cell, or, to a much smaller extent, Cu^{2+} ions can leave the solution and enter the salt bridge. Both processes help keep the copper half-cell electrically neutral. In the silver half-cell, positive ions from the salt bridge can enter or negative $\text{NO}_3{}^-$ ions can, once again to a much smaller extent, leave the half-cell by entering the salt bridge, to keep it electrically neutral, too.

■ Often the salt bridge is prepared by saturating a hot agar–agar solution with KNO_3 or KCl. After pouring into a U-shaped tube the agar–agar solidifies on cooling. The salt ions can move but the agar–agar does not flow out of the salt bridge.



Reduction of silver ions at the cathode extracts electrons from the electrode, so the electrode becomes positively charged.

Oxidation of copper atoms at the anode leaves electrons behind on the electrode, which becomes negatively charged.

Figure 20.3 | **Expanded view of Figure 20.2 to show changes that take place at the anode and cathode in the copper–silver galvanic cell.** (Not drawn to scale.) At the anode, Cu^{2+} ions enter the solution when copper atoms are oxidized, leaving electrons behind on the electrode. Unless Cu^{2+} ions move away from the electrode or NO_3^- ions move toward it, the solution around the electrode will become positively charged. At the cathode, Ag^+ ions leave the solution and become silver atoms by acquiring electrons from the electrode surface. Unless more silver ions move toward the cathode or negative ions move away, the solution around the electrode will become negatively charged.

Without the salt bridge, electrical neutrality could not be maintained and no electrical current could be produced by the cell. Therefore, *electrolytic contact*—contact by means of a solution containing ions—must be maintained for the cell to function.

If we look closely at the overall movement of ions during the operation of the galvanic cell, we find that negative ions (*anions*) move away from the cathode, where they are present in excess, and *toward the anode*, where they are needed to balance the charge of the positive ions being formed. Similarly, we find that positive ions (*cations*) move away from the anode, where they are in excess, and *toward the cathode*, where they can balance the charge of the anions left in excess. In fact, the reason positive ions are called cations and negative ions are called anions is because of the nature of the electrodes toward which they move. In summary:

> Cations move in the general direction of the cathode.
>
> Anions move in the general direction of the anode.

Charges of the Electrodes

At the anode of the galvanic cell described in Figures 20.2 and 20.3, copper atoms spontaneously leave the electrode and enter the solution as Cu^{2+} ions. The electrons that are left behind give the anode a slight negative charge. (We say the anode has a *negative polarity*.) At the cathode, electrons spontaneously join Ag^+ ions to produce neutral atoms, but the effect is the same as if Ag^+ ions become part of the electrode, so the cathode acquires a slight positive charge. (The cathode has a *positive polarity*.) During the operation of the cell, the amount of positive and negative charge on the electrodes is kept small by the flow of electrons (an electric current) through the external circuit from the anode to the cathode when the circuit is complete. In fact, unless electrons can flow out of the anode and into the cathode, the chemical reactions that occur at their surfaces will cease.

■ The small difference in charge between the electrodes is formed by the spontaneity of the overall reaction, that is, by the favorable free energy change. Nature's tendency toward electrical neutrality prevents a large buildup of charge on the electrodes and promotes the spontaneous flow of electricity through the external circuit.

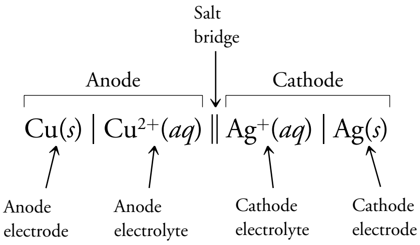
Standard Cell Notation

As a matter of convenience, chemists have devised a shorthand way of describing the makeup of a galvanic cell. For example, the copper–silver cell that we have been using in our discussion is represented as follows:

$$Cu(s) \mid Cu^{2+}(aq) \parallel Ag^{+}(aq) \mid Ag(s)$$

By convention, in **standard cell notation**, the anode half-cell is specified on the left, with the electrode material of the anode given first. In this case, the anode is copper metal. The single vertical bar represents the *phase boundary* between the copper electrode and the solution that surrounds it. The double vertical bars represent the two phase boundaries, one at each end of the salt bridge, which connects the solutions in the two half-cells. On the right, the cathode half-cell is described, with the material of the cathode given last. Thus, the electrodes themselves (copper and silver) are specified at opposite ends of the cell description.

■ Standard cell notation is also called a cell diagram.



$$\mathrm{Cu}(s) \mid \mathrm{Cu}^{2+}(aq) \parallel \mathrm{Ag}^{+}(aq) \mid \mathrm{Ag}(s)$$

■ In the anode compartment, Cu is the reactant and is oxidized to Cu^{2+}, whereas in the cathode compartment, Ag^+ is the reactant and is reduced to Ag.

Sometimes, both the oxidized and reduced forms of the reactants in a half-cell are soluble and cannot be used as an electrode. In these cases, an inert electrode composed of platinum or gold is used to provide a site for electron transfer. For example, a galvanic cell can be made using an anode composed of a zinc electrode dipping into a solution containing Zn^{2+} and a cathode composed of a platinum electrode dipping into a solution containing both Fe^{2+} and Fe^{3+} ions. The cell reaction is

$$2\mathrm{Fe}^{3+}(aq) + \mathrm{Zn}(s) \longrightarrow 2\mathrm{Fe}^{2+}(aq) + \mathrm{Zn}^{2+}(aq)$$

The cell notation for this galvanic cell is written as follows:

$$\mathrm{Zn}(s) \mid \mathrm{Zn}^{2+}(aq) \parallel \mathrm{Fe}^{2+}(aq), \mathrm{Fe}^{3+}(aq) \mid \mathrm{Pt}(s)$$

where we have separated the formulas for the two iron ions by a comma. In this cell, the reduction of the Fe^{3+} to Fe^{2+} takes place at the surface of the inert platinum electrode.

■ Since they are thoroughly mixed in solution, it does not matter if Fe^{2+} or Fe^{3+} is written first.

Example 20.1

Describing Galvanic Cells

The following spontaneous reaction occurs when metallic zinc is dipped into a solution of copper sulfate.

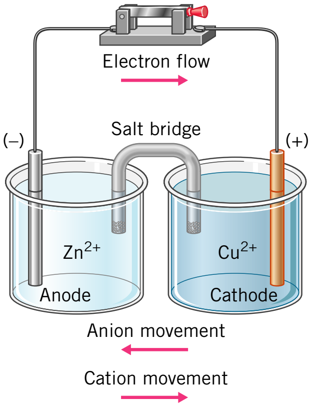
$$\mathrm{Zn}(s) + \mathrm{Cu}^{2+}(aq) \longrightarrow \mathrm{Zn}^{2+}(aq) + \mathrm{Cu}(s)$$

Describe a galvanic cell that could take advantage of this reaction. What are the half-cell reactions? What is the standard cell notation? Make a sketch of the cell and label the cathode and anode, the charges on each electrode, the direction of ion flow, and the direction of electron flow.

■ **Analysis:** Answering all these questions relies on identifying the anode and cathode in the equation for the cell reaction; this is often the key to solving problems of this type. By definition, the anode is the electrode at which oxidation happens, and the cathode is where reduction occurs.

■ **Assembling the Tools:** We can use the principles of the ion–electron method for balancing redox reactions that were learned in Section 6.2. When the half-reactions are balanced, the one with electrons as reactants is the reduction half-reaction and the one where electrons are products is the oxidation half-reaction.

$$\begin{array}{rll} \mathrm{Zn}(s) \longrightarrow & \mathrm{Zn}^{2+}(aq) + 2e^- & \qquad \text{(anode reaction)} \\ \mathrm{Cu}^{2+}(aq) + 2e^- \longrightarrow & \mathrm{Cu}(s) & \qquad \text{(cathode reaction)} \end{array}$$



The zinc-copper cell. In the cell notation described in this example, we indicate the anode on the left and the cathode on the right. In this drawing of the apparatus, the anode half-cell is also shown on the left, but it could just as easily be shown on the right, as in Figure 20.2. Be sure you understand that where we place the apparatus on the lab bench doesn't affect which half-cell is the anode and which is the cathode.

We will use the procedures just discussed to write the standard cell notation and draw our diagram.

Solution: We start writing the standard cell notation with the anode itself. Since Zn(*s*) is a metal, it can be used as the anode. The anode half-cell is therefore a zinc electrode dipping into a solution that contains Zn^{2+} [e.g., from dissolved $Zn(NO_3)_2$ or $ZnSO_4$]. Symbolically, the anode half-cell is written with the electrode material at the left of the vertical bar and the oxidation product at the right.

$$Zn(s) \mid Zn^{2+}(aq)$$

Copper ions gain electrons and are reduced to metallic copper, which we can use as the cathode. So the cathode half-cell consists of a copper electrode dipping into a solution containing Cu^{2+} [e.g., from dissolved $Cu(NO_3)_2$ or $CuSO_4$]. The copper half-cell is represented with the electrode material to the right of the vertical bar and the substance reduced on the left.

$$Cu^{2+}(aq) \mid Cu(s)$$

The standard cell notation places the zinc anode half-cell on the left and the copper cathode half-cell on the right, separated by double bars that represent the salt bridge.

$$\underbrace{Zn(s) \mid Zn^{2+}(aq)}_{\text{anode}} \parallel \underbrace{Cu^{2+}(aq) \mid Cu(s)}_{\text{cathode}}$$

A sketch of the cell is shown in the margin. The anode always carries a negative charge in a galvanic cell, so the zinc electrode is negative and the copper electrode is positive. Electrons in the external circuit travel from the negative electrode to the positive electrode (i.e., from the Zn anode to the Cu cathode). Anions move toward the anode and cations move toward the cathode. In the salt bridge we also find that anions will flow toward the anode and cations toward the cathode as shown.

Are the Answers Reasonable? All of the answers depend on determining which substance is oxidized and which is reduced, so we check that first. Oxidation is electron loss, and Zn must lose electrons to become Zn^{2+}, so zinc is oxidized and must be the anode. If zinc is the anode, then copper must be the cathode. We can then reason that the oxidation of zinc produces electrons that flow from the anode to the cathode.

Practice Exercises

20.1 | Sketch and label a galvanic cell that makes use of the following spontaneous redox reaction.

$$Mg(s) + Fe^{2+}(aq) \longrightarrow Mg^{2+}(aq) + Fe(s)$$

Write the half-reactions for the anode and cathode. Give the standard cell notation. (*Hint*: Determine which half-reaction represents oxidation and which represents reduction.)

20.2 | Write the anode and cathode half-reactions for the following galvanic cell. Write the equation for the overall cell reaction.

$$Al(s) \mid Al^{3+}(aq) \parallel Ni^{2+}(aq) \mid Ni(s)$$

Sketch and label a galvanic cell that corresponds to this standard cell notation.

20.2 | Cell Potentials

The potential generated by a galvanic cell has also been called the **electromotive force (emf)**. Modern electrochemistry uses the preferred E_{cell} or E°_{cell} to note cell potentials and standard cell potentials, respectively.

A galvanic cell has an ability to push electrons through the external circuit. The magnitude of this ability is expressed as a **potential**. Potential is expressed in an electrical unit called the **volt (V),** which is a measure of the amount of energy, in joules, that can be delivered per **coulomb** (the SI unit of charge) as the charges move through the circuit. Thus, a charge flowing under a potential of 1 volt can deliver 1 joule of energy per coulomb.

$$1\ V = 1\ J/C \tag{20.1}$$

The voltage or potential of a galvanic cell varies with the amount of charge flowing through the circuit. The *maximum* potential that a given cell can generate is called its **cell potential, E_{cell}**, and it depends on the composition of the electrodes, the concentrations of the ions in the half-cells, and the temperature. The standard state for electrochemistry is defined as a system where the temperature is 25 °C, all concentrations are 1.00 *M*, and any gases are at 1.00 atm pressure. When the system is at standard state, the potential of a galvanic cell is the **standard cell potential,** symbolized by E°_{cell}.

Cell potentials are rarely larger than a few volts. For example, the standard cell potential for the galvanic cell constructed from silver and copper electrodes shown in Figure 20.4 is only 0.46 V, and one cell in an automobile battery produces only about 2 V. Batteries that generate higher voltages, such as the automobile battery, contain a number of cells connected one after the other (i.e., in series) so that their potentials are additive.

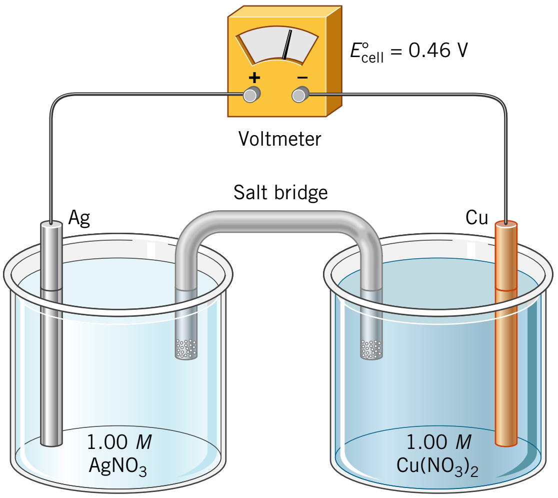


Figure 20.4 | **A cell designed to generate the standard cell potential.** The concentrations of the Cu^{2+} and Ag^+ ions in the half-cells are 1.00 *M*. It is very important to always connect the negative terminal of the voltmeter to the anode for correct readings.

In Section 20.5 we will see that we can calculate the cell potential, E_{cell}, for systems that are not at standard state. As long as we know the temperature, concentration of solutes and pressures of gases, we will be able to calculate how much the cell potential differs from the standard cell potential. Without getting into the details that are presented later, it is important to note that in most cases the standard cell potential and the calculated cell potential for a reaction usually differ by less than 0.5 volt and usually have the same algebraic sign. Therefore we will make generalizations and demonstrate them using standard reduction potentials. These generalizations will usually apply to nonstandard state cell potentials.

■ If charge flows from a cell, some of the cell's voltage is lost overcoming its own internal resistance, and the measured voltage is less than the original E_{cell}.

Reduction Potentials

It is useful to think of each half-cell as having a certain natural tendency to acquire electrons and proceed as a *reduction.* The magnitude of this tendency is expressed by the half-reaction's **reduction potential.** When measured under standard conditions, namely, 25 °C, concentrations of 1.00 *M* for all solutes, and pressures of 1 atm for all gases, the reduction potential is called the **standard reduction potential.** To represent a standard reduction potential, we will add a subscript to the symbol $E°$ that identifies the substance undergoing reduction. Thus, the standard reduction potential for the half-reaction

$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$$

is specified as $E^\circ_{Cu^{2+}}$.

■ Standard reduction potentials are also called **standard electrode potentials**.

When two half-cells are connected to make a Galvanic cell, the one with the larger standard reduction potential (the one with the greater tendency to undergo reduction) acquires electrons from the half-cell with the lower standard reduction potential, which is therefore forced to undergo oxidation. The standard cell potential, which is always taken to be a positive number, represents the *difference* between the standard reduction potential of one half-cell and the standard reduction potential of the other. In general, therefore,

$$E^\circ_{cell} = \begin{pmatrix}\text{standard reduction}\\ \text{potential of the}\\ \text{substance reduced}\end{pmatrix} - \begin{pmatrix}\text{standard reduction}\\ \text{potential of the}\\ \text{substance oxidized}\end{pmatrix} \qquad \textbf{(20.2)}$$

■ In a galvanic cell, the measured cell potential is *always* taken to be a positive value. This is important to remember.

TOOLS

Standard reduction potentials used to calculate E°_{cell}

As an example, let's look at the copper–silver cell. From the cell reaction,

$$2Ag^+(aq) + Cu(s) \longrightarrow 2Ag(s) + Cu^{2+}(aq)$$

we can see that silver ions are reduced and copper is oxidized. If we compare the two possible reduction half-reactions,

$$Ag^+(aq) + e^- \longrightarrow Ag(s)$$
$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$$

■ Notice that we use the standard cell potentials without any adjustment for the number of electrons in the half reaction.

the one for Ag^+ must have a greater tendency to proceed than the one for Cu^{2+}, because it is the silver ion that is actually reduced. This means that the standard reduction potential of Ag^+ must be more positive than the standard reduction potential of Cu^{2+}. In other words, if we knew the values of $E^\circ_{Ag^+}$ and $E^\circ_{Cu^{2+}}$, we could calculate E°_{cell} with Equation 20.2 by subtracting the less positive standard reduction potential (copper) from the more positive one (silver), always resulting in a positive number.

$$E^\circ_{cell} = E^\circ_{Ag^+} - E^\circ_{Cu^{2+}}$$

The Hydrogen Electrode

Unfortunately there is no way to measure the standard reduction potential of an isolated half-cell. All we can measure is the difference in potential produced when two half-cells are connected. Therefore, to assign numerical values for standard reduction potentials, a reference electrode has been arbitrarily chosen and its standard reduction potential has been defined as *exactly* ***zero volts.*** This reference electrode is called the **standard hydrogen electrode** (see Figure 20.5). Gaseous hydrogen at a pressure of 1.00 atm is bubbled over a platinum electrode coated with very finely divided platinum, which provides a large catalytic surface area on which the electrode reaction can occur. This electrode is surrounded by a solution whose temperature is 25 °C and in which the hydrogen ion concentration is 1.00 *M*. The half-cell reaction at the platinum surface, written as a reduction, is

$$2H^+(aq,\ 1.00\ M) + 2e^- \rightleftharpoons H_2(g,\ 1.00\ \text{atm}) \qquad E^\circ_{H^+} \equiv 0\ \text{V (exactly)}$$

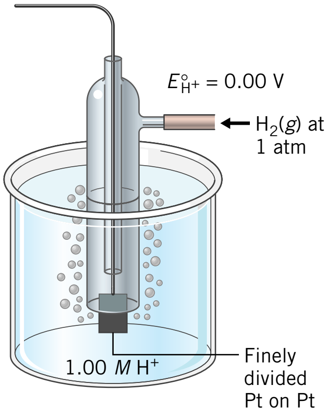

Figure 20.5 | **The hydrogen electrode.** The half-reaction is $2H^+(aq) + 2e^- \rightleftharpoons H_2(g)$.

The double arrows indicate only that the reaction is reversible, not that there is true equilibrium. Whether the half-reaction occurs as reduction or oxidation depends on the standard reduction potential of the half-cell with which it is paired.

Figure 20.6 illustrates the hydrogen electrode connected to a copper half-cell to form a galvanic cell. When we use a voltmeter to measure the potential of the cell, we find that the copper electrode has a positive charge and the hydrogen electrode has a negative charge. Therefore, copper must be the cathode, and Cu^{2+} is reduced to Cu when the cell operates. Similarly, hydrogen must be the anode, and H_2 is oxidized to H^+. The half-reactions and cell reaction, therefore, are

$$\begin{array}{rll} Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s) & & \text{(cathode)} \\ H_2(g) \longrightarrow 2H^+(aq) + 2e^- & & \text{(anode)} \\ \hline Cu^{2+}(aq) + H_2(g) \longrightarrow Cu(s) + 2H^+(aq) & & \text{(cell reaction)}^1 \end{array}$$

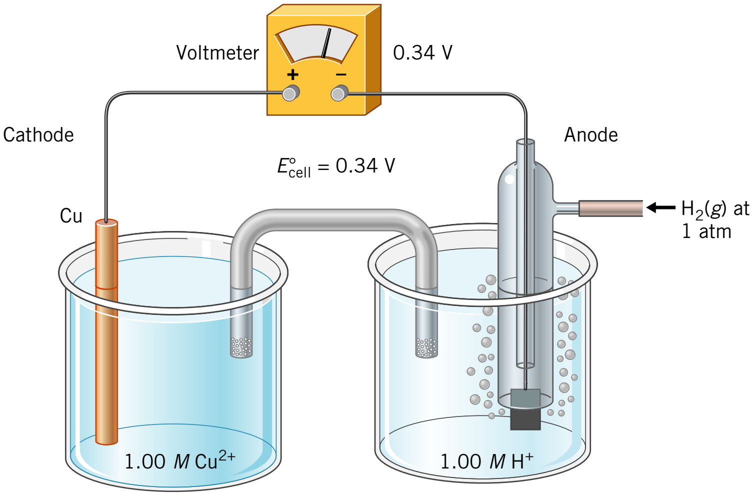

Figure 20.6 | **A galvanic cell composed of copper and hydrogen half-cells.** The cell reaction is $Cu^{2+}(aq) + H_2(g) \longrightarrow Cu(s) + 2H^+(aq)$.

---

[1] The cell notation for this cell is written as

$$Pt(s)\ |\ H_2(g)\ |\ H^+(aq)\ ||\ Cu^{2+}(aq)\ |\ Cu(s)$$

The notation for the hydrogen electrode (the anode in this case) is shown at the left of the double vertical bars.

Using Equation 20.2, we can express E°_{cell} in terms of $E^\circ_{\text{Cu}^{2+}}$ and $E^\circ_{\text{H}^+}$.

$$E^\circ_{\text{cell}} = \underbrace{E^\circ_{\text{Cu}^{2+}}}_{\text{Reduction potential of the substance reduced}} - \underbrace{E^\circ_{\text{H}^+}}_{\text{Reduction potential of the substance oxidized}}$$

The measured standard cell potential is 0.34 V, and $E^\circ_{\text{H}^+}$ equals 0.00 V. Therefore,

$$0.34\text{ V} = E^\circ_{\text{Cu}^{2+}} - 0.00\text{ V}$$

Relative to the hydrogen electrode, then, the standard reduction potential of Cu^{2+} is +0.34 V. (We have written the value with a plus sign because some standard reduction potentials are negative, as we will see.)

Now let's look at a galvanic cell set up between a zinc electrode and a hydrogen electrode (see Figure 20.7). This time we find that the hydrogen electrode is positive and the zinc electrode is negative, which tells us that the hydrogen electrode is the cathode and the zinc electrode is the anode. This means that the hydrogen ion is being reduced and zinc is being oxidized. Based on this reasoning the half-reactions and cell reaction are

$$\begin{array}{rl} 2\text{H}^+(aq) + 2e^- \longrightarrow \text{H}_2(g) & \text{(cathode)} \\ \text{Zn}(s) \longrightarrow \text{Zn}^{2+}(aq) + 2e^- & \text{(anode)} \\ \hline 2\text{H}^+(aq) + \text{Zn}(s) \longrightarrow \text{H}_2(g) + \text{Zn}^{2+}(aq) & \text{(cell reaction)}^2 \end{array}$$

From Equation 20.2, the standard cell potential is given by

$$E^\circ_{\text{cell}} = E^\circ_{\text{H}^+} - E^\circ_{\text{Zn}^{2+}}$$

Substituting into this the measured standard cell potential of 0.76 V and $E^\circ_{\text{H}^+} = 0.00$ V, we have

$$0.76\text{ V} = 0.00\text{ V} - E^\circ_{\text{Zn}^{2+}}$$

which gives

$$E^\circ_{\text{Zn}^{2+}} = -0.76\text{ V}$$

Notice that the standard reduction potential of zinc is negative. A negative standard reduction potential simply means that the substance is not as easily reduced as H^+. In this case, it tells us that Zn is oxidized when it is paired with the hydrogen electrode.

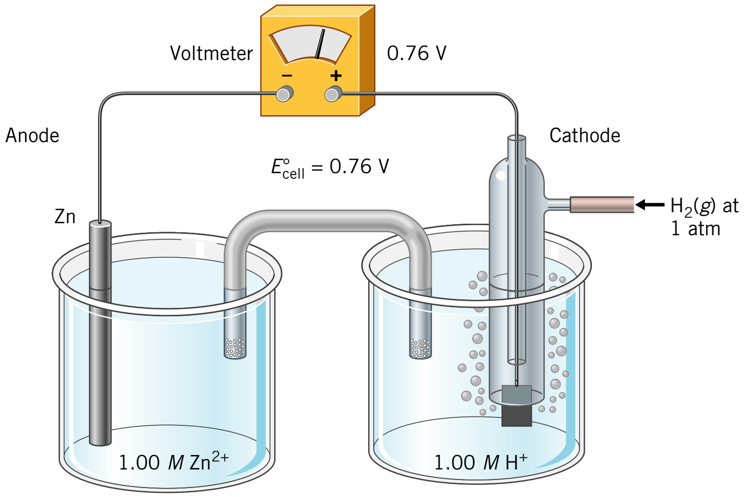

Figure 20.7 | **A galvanic cell composed of zinc and hydrogen half-cells.** The cell reaction is $\text{Zn}(s) + 2\text{H}^+(aq) \longrightarrow \text{Zn}^{2+}(aq) + \text{H}_2(g)$.

---

[2] This cell is represented as

$$\text{Zn}(s) \mid \text{Zn}^{2+}(aq) \parallel \text{H}^+(aq) \mid \text{H}_2(g) \mid \text{Pt}(s)$$

This time the hydrogen electrode is the cathode and appears at the right of the double vertical bars.

The standard reduction potentials of many half-reactions can be compared to that for the standard hydrogen electrode in the manner we just described. Table 20.1 lists values obtained for some typical half-reactions. They are arranged in decreasing order—the half-reactions at the top have the greatest tendency to occur as reductions, while those at the bottom have the least tendency to occur as reduction reactions.

■ Substances located to the left of the double arrows are *oxidizing agents*, because they become reduced when the reactions proceed in the forward direction. The best oxidizing agents are those most easily reduced, and they are located at the top of the table (e.g., F_2).

Table 20.1 Standard Reduction Potentials at 25 °C[a]

Half-Reaction	$E°$ (volts)
$F_2(g) + 2e^- \rightleftharpoons 2F^-(aq)$	+2.87
$S_2O_8^{2-}(aq) + 2e^- \rightleftharpoons 2SO_4^{2-}(aq)$	+2.01
$PbO_2(s) + HSO_4^-(aq) + 3H^+(aq) + 2e^- \rightleftharpoons PbSO_4(s) + 2H_2O$	+1.69
$2HOCl(aq) + 2H^+(aq) + 2e^- \rightleftharpoons Cl_2(g) + 2H_2O$	+1.63
$MnO_4^-(aq) + 8H^+(aq) + 5e^- \rightleftharpoons Mn^{2+}(aq) + 4H_2O$	+1.51
$PbO_2(s) + 4H^+(aq) + 2e^- \rightleftharpoons Pb^{2+}(aq) + 2H_2O$	+1.46
$BrO_3^-(aq) + 6H^+(aq) + 6e^- \rightleftharpoons Br^-(aq) + 3H_2O$	+1.44
$Au^{3+}(aq) + 3e^- \rightleftharpoons Au(s)$	+1.42
$Cl_2(g) + 2e^- \rightleftharpoons 2Cl^-(aq)$	+1.36
$O_2(g) + 4H^+(aq) + 4e^- \rightleftharpoons 2H_2O$	+1.23
$Br_2(aq) + 2e^- \rightleftharpoons 2Br^-(aq)$	+1.07
$NO_3^-(aq) + 4H^+(aq) + 3e^- \rightleftharpoons NO(g) + 2H_2O$	+0.96
$Ag^+(aq) + e^- \rightleftharpoons Ag(s)$	+0.80
$Fe^{3+}(aq) + e^- \rightleftharpoons Fe^{2+}(aq)$	+0.77
$I_2(s) + 2e^- \rightleftharpoons 2I^-(aq)$	+0.54
$NiO_2(s) + 2H_2O + 2e^- \rightleftharpoons Ni(OH)_2(s) + 2OH^-(aq)$	+0.49
$Cu^{2+}(aq) + 2e^- \rightleftharpoons Cu(s)$	+0.34
$SO_4^{2-}(aq) + 4H^+(aq) + 2e^- \rightleftharpoons H_2SO_3(aq) + H_2O$	+0.17
$AgBr(s) + e^- \rightleftharpoons Ag(s) + Br^-(aq)$	+0.07
$2H^+(aq) + 2e^- \rightleftharpoons H_2(g)$	0
$Sn^{2+}(aq) + 2e^- \rightleftharpoons Sn(s)$	−0.14
$Ni^{2+}(aq) + 2e^- \rightleftharpoons Ni(s)$	−0.25
$Co^{2+}(aq) + 2e^- \rightleftharpoons Co(s)$	−0.28
$PbSO_4(s) + H^+(aq) + 2e^- \rightleftharpoons Pb(s) + HSO_4^-(aq)$	−0.36
$Cd^{2+}(aq) + 2e^- \rightleftharpoons Cd(s)$	−0.40
$Fe^{2+}(aq) + 2e^- \rightleftharpoons Fe(s)$	−0.44
$Cr^{3+}(aq) + 3e^- \rightleftharpoons Cr(s)$	−0.74
$Zn^{2+}(aq) + 2e^- \rightleftharpoons Zn(s)$	−0.76
$2H_2O + 2e^- \rightleftharpoons H_2(g) + 2OH^-(aq)$	−0.83
$Al^{3+}(aq) + 3e^- \rightleftharpoons Al(s)$	−1.66
$Mg^{2+}(aq) + 2e^- \rightleftharpoons Mg(s)$	−2.37
$Na^+(aq) + e^- \rightleftharpoons Na(s)$	−2.71
$Ca^{2+}(aq) + 2e^- \rightleftharpoons Ca(s)$	−2.76
$K^+(aq) + e^- \rightleftharpoons K(s)$	−2.92
$Li^+(aq) + e^- \rightleftharpoons Li(s)$	−3.05

[a] See Appendix Table C.9 for a more complete listing.

■ Substances located to the right of the double arrows are *reducing agents*; they become oxidized when the reactions proceed from right to left. The best reducing agents are those found at the bottom of the table (e.g., Li).

CHEMISTRY OUTSIDE THE CLASSROOM 20.1

Corrosion of Iron and Cathodic Protection

A problem that has plagued humanity ever since the discovery of methods for obtaining iron and other metals from their ores has been corrosion—the reaction of a metal with substances in the environment. The rusting of iron in particular is a serious problem because iron and steel have so many uses.

The rusting of iron is a complex chemical reaction that involves both oxygen and moisture (see Figure 1). Iron won't rust in pure water that's oxygen free, and it won't rust in pure oxygen in the absence of moisture. The corrosion process is apparently electrochemical in nature, as shown in the accompanying diagram. At one place on the surface, iron becomes oxidized in the presence of water and enters solution as Fe^{2+}.

$$Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$$

At this location the iron is acting as an anode.

The electrons that are released when the iron is oxidized travel through the metal to some other place where the iron is exposed to oxygen. This is where reduction takes place (it's a cathodic region on the metal surface), and oxygen is reduced to give hydroxide ion.

$$\tfrac{1}{2}O_2(aq) + H_2O + 2e^- \longrightarrow 2OH^-(aq)$$

The iron(II) ions that are formed at the anodic regions gradually diffuse through the water and eventually contact the hydroxide ions. This causes a precipitate of $Fe(OH)_2$ to form, which is very easily oxidized by O_2 to give $Fe(OH)_3$. This hydroxide readily loses water. In fact, complete dehydration gives the oxide,

$$2Fe(OH)_3 \longrightarrow Fe_2O_3 + 3H_2O$$

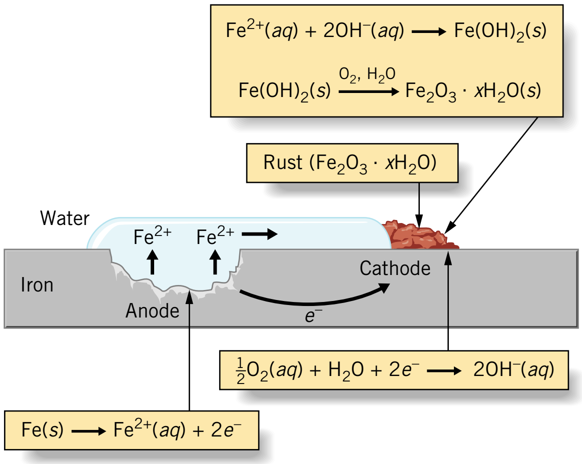
When partial dehydration of the $Fe(OH)_3$ occurs, *rust* is formed. It has a composition that lies between that of the hydroxide and that of the oxide, Fe_2O_3, and is usually referred to as a *hydrated oxide*. Its formula is generally represented as $Fe_2O_3 \cdot xH_2O$.

This mechanism for the rusting of iron explains one of the more interesting aspects of this damaging process. Perhaps you've noticed that when rusting occurs on the body of a car, the rust appears at and around a break (or a scratch) in the surface of the paint, but the damage extends under the painted surface for some distance. Apparently, the Fe^{2+} ions that are formed at the anode sites are able to diffuse rather long distances to the hole in the paint, where they finally react with air to form the rust.

Cathodic Protection

One way to prevent the rusting of iron is to coat it with another metal. This is done with "tin" cans, which are actually steel cans that have been coated with a thin layer of tin. However, if the layer of tin is scratched and the iron beneath is exposed, the corrosion is accelerated because iron has a lower reduction potential than tin; the iron becomes the anode in an electrochemical cell and is easily oxidized.

Another way to prevent corrosion is called *cathodic protection*. It involves placing the iron in contact with a metal that is *more easily* oxidized. This causes iron to be a cathode and the other metal to be the anode. If corrosion occurs, the iron is protected from oxidation because it is cathodic and the other metal reacts instead.



$Fe^{2+}(aq) + 2OH^-(aq) \longrightarrow Fe(OH)_2(s)$
$Fe(OH)_2(s) \xrightarrow{O_2,\ H_2O} Fe_2O_3 \cdot xH_2O(s)$
Rust ($Fe_2O_3 \cdot xH_2O$)
Water
Fe^{2+}
Fe^{2+}
Iron
Cathode
Anode
e^-
$\tfrac{1}{2}O_2(aq) + H_2O + 2e^- \longrightarrow 2OH^-(aq)$
$Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$

Figure 1 **Corrosion of iron.** Iron dissolves in anodic regions to give Fe^{2+}. Electrons travel through the metal to cathodic sites where oxygen is reduced, forming OH^-. The combination of the Fe^{2+} and OH^-, followed by air oxidation, gives rust.

Zinc is most often used to provide cathodic protection to other metals. For example, zinc sacrificial anodes can be attached to the rudder of a boat (see Figure 2). When the rudder is submerged, the zinc will gradually corrode but the metal of the rudder will not. Periodically, the anodes are replaced to provide continued protection.

Steel objects that must withstand the weather are often coated with a layer of zinc, a process called galvanizing. You've probably seen this on chain-link fences and metal garbage pails. Even if the steel is exposed through a scratch, it is not oxidized because it is in contact with a metal that is more easily oxidized.

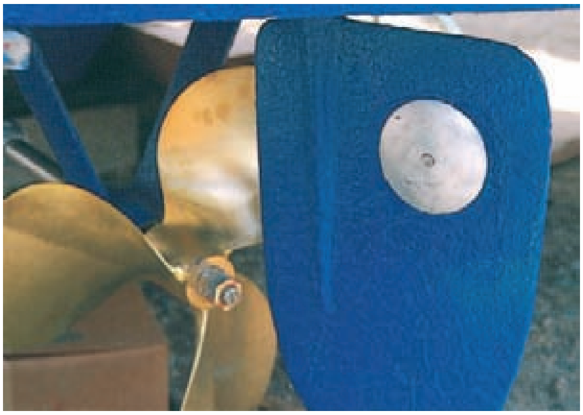


Figure 2 **Cathodic protection.** Before launching, a shiny new zinc anode disk is attached to the bronze rudder of this boat to provide cathodic protection. Over time, the zinc will corrode instead of the less reactive bronze. (The rudder is painted with a special blue paint to inhibit the growth of barnacles.) *(Courtesy James Brady)*

Example 20.2
Calculating Standard Cell Potentials

We mentioned earlier that the standard cell potential of the silver–copper galvanic cell has a value of +0.46 V. The cell reaction is

$$2\text{Ag}^+(aq) + \text{Cu}(s) \longrightarrow 2\text{Ag}(s) + \text{Cu}^{2+}(aq)$$

and we have seen that the standard reduction potential of Cu^{2+}, $E^\circ_{\text{Cu}^{2+}}$, is +0.34 V. What is the value of the standard reduction potential of Ag^+, $E^\circ_{\text{Ag}^+}$?

Analysis: The standard cell potential is the difference between two standard reduction potentials. Since we know two of these three variables, we just have to be sure our math is correct.

Assembling the Tools: We know the standard potential of the cell and one of the two standard reduction potentials, so Equation 20.2 will be our tool to calculate the unknown standard reduction potential. The principles of oxidation and reduction will be used to determine which reactant is reduced and which is oxidized, allowing us to set up the equation correctly.

Solution: Silver changes from Ag^+ to Ag; its oxidation number decreases from +1 to 0, so we conclude that Ag^+ is reduced. Similar reasoning tells us that copper is oxidized from Cu to Cu^{2+}. Therefore, according to Equation 20.2,

$$E^\circ_{\text{cell}} = \underset{\substack{\uparrow \\ \text{Standard reduction} \\ \text{potential of substance} \\ \text{reduced}}}{E^\circ_{\text{Ag}^+}} - \underset{\substack{\uparrow \\ \text{Standard reduction} \\ \text{potential of substance} \\ \text{oxidized}}}{E^\circ_{\text{Cu}^{2+}}}$$

Substituting values for E°_{cell} and $E^\circ_{\text{Cu}^{2+}}$,

$$0.46 \text{ V} = E^\circ_{\text{Ag}^+} - 0.34 \text{ V}$$

Then we solve for $E^\circ_{\text{Ag}^+}$.

$$\begin{aligned} E^\circ_{\text{Ag}^+} &= 0.46 \text{ V} + 0.34 \text{ V} \\ &= 0.80 \text{ V} \end{aligned}$$

The standard reduction potential of silver ion is therefore +0.80 V.

Is the Answer Reasonable? We know the standard cell potential is the difference between the two standard reduction potentials. The difference between +0.80 V and +0.34 V (subtracting the smaller from the larger) is 0.46 V. Our calculated standard reduction potential for Ag^+ appears to be correct. You can also take a peek at Table 20.1 now for a final check.

Practice Exercises

20.3 | Copper metal and zinc metal will both reduce Ag^+ ions under standard state conditions. Which metal when used as an electrode in a galvanic cell will have the larger E°_{cell} under these conditions? (*Hint*: Write the two possible chemical reactions.)

20.4 | The galvanic cell described in Practice Exercise 20.1 has a standard cell potential of 1.93 V. The standard reduction potential of Mg^{2+} corresponding to the half-reaction $\text{Mg}^{2+}(aq) + 2e^- \rightleftharpoons \text{Mg}(s)$ is −2.37 V. Calculate the standard reduction potential of iron(II). Check your answer by referring to Table 20.1.

At this point you may have wondered why the term *cell potential* is used in some places and *standard cell potential* is used in others. Based on our definitions, the term standard cell potential is used in places where the system is at standard state (i.e., 1.00 *M* concentrations, 1.00 *atm* pressures, and 25.0 °C). Cell potential is used for *any* set of concentrations, pressures, and temperatures, including the standard conditions. For convenience, our calculations in the next two sections will use standard cell potentials.

20.3 | Standard Reduction Potentials

In the previous section we saw how to define standard reduction potentials and standard cell potentials. In addition, by defining the standard reduction potential of the hydrogen electrode, we saw that standard reduction potentials could be determined. Now we will begin investigating some of the uses of standard cell potentials.

Predicting Spontaneous Reactions

It's easy to predict the spontaneous reaction when the substances in two half-reactions, at standard state, are mixed together. This is because we know that *the half-reaction with the more positive reduction potential always takes place as written (namely, as a reduction), while the other half-reaction is forced to run in reverse (as an oxidation).*

■ Strictly speaking, the $E°$ values only tell us what to expect under standard conditions. However, only when $E°_{\text{cell}}$ is small can changes in the concentrations change the direction of the spontaneous reaction.

Example 20.3

Predicting a Spontaneous Reaction

What spontaneous reaction occurs if Cl_2 and Br_2 are added to a solution that contains both Cl^- and Br^-? Assume standard conditions.

■ **Analysis:** We know that in the spontaneous redox reaction, the more easily reduced substance will be the one that undergoes reduction. We need the data to decide which substance will be reduced, Cl_2 or Br_2; we already know that neither Cl^- nor Br^- can be reduced since they cannot be in lower oxidation states.

■ **Assembling the Tools:** By assuming we are at standard state, we can use the standard reduction potentials for Cl_2 and Br_2 in Table 20.1 to compare their $E°$ values to determine the combination that results in a spontaneous reaction. There are two possible reduction half-reactions:

$$\mathrm{Cl_2}(g) + 2e^- \longrightarrow 2\mathrm{Cl}^-(aq)$$
$$\mathrm{Br_2}(aq) + 2e^- \longrightarrow 2\mathrm{Br}^-(aq)$$

and we need to decide which is the reduction and which is the oxidation half-reaction. This is the spontaneous reaction, so Equation 20.2 must yield a positive result *whether or not the reaction occurs in a galvanic cell.*

■ **Solution:** Referring to Table 20.1, we find that Cl_2 has a more positive standard reduction potential (+1.36 V) than does Br_2 (+1.07 V). This means Cl_2 will be reduced and the half-reaction for Br_2 will be reversed, changing it to an oxidation process. Therefore, the spontaneous reaction has the following half-reactions.

$$\mathrm{Cl_2}(g) + 2e^- \longrightarrow 2\mathrm{Cl}^-(aq) \qquad \text{(a reduction)}$$
$$2\mathrm{Br}^-(aq) \longrightarrow \mathrm{Br_2}(aq) + 2e^- \qquad \text{(an oxidation)}$$

The net reaction is obtained by combining the half-reactions.

$$\mathrm{Cl_2}(g) + 2\mathrm{Br}^-(aq) \longrightarrow \mathrm{Br_2}(aq) + 2\mathrm{Cl}^-(aq)$$

■ **Is the Answer Reasonable?** We can check to be sure we've read the correct values for $E°_{\mathrm{Cl_2}}$ and $E°_{\mathrm{Br_2}}$ from Table 20.1, and we can check the half-reactions we used to find the equation for the net reaction. (Experimentally, chlorine does indeed oxidize bromide ion to bromine, a fact used to recover bromine from seawater and natural brine solutions.)

When conditions are at standard state, reactants and products of *spontaneous* redox reactions are easy to spot when standard reduction potentials are listed in order of most positive to least positive (most negative), as in Table 20.1. For *any* pair of half-reactions, the one higher up in the table has the more positive standard reduction potential and occurs as a reduction. The other half-reaction is reversed and occurs as an oxidation. *Therefore, for a spontaneous reaction, the* ***reactants*** *are found on the left side of the higher half-reaction and on the right side of the lower half-reaction. (Also, this is usually, but not always, true of systems that are not at standard state.)*

Practice Exercises

20.5 | Based only on the half-reactions in Table 20.1, determine what spontaneous reaction will occur if the following substances are mixed together: (a) I_2, I^- and Fe^{2+}, Fe^{3+}; (b) Mg, Mg^{2+} and Cr, Cr^{3+}; (c) Co, Co^{2+} and H_2SO_3, SO_4^{2-}. (*Hint*: Use Table 20.1 to write the possible half-reactions and, if necessary, determine E°_{cell}.)

20.6 | Use the positions of the half-reactions in Table 20.1 to predict the spontaneous reaction when Br^-, SO_4^{2-}, H_2SO_3, and Br_2 are mixed in an acidic solution at standard state.

20.7 | From the positions of the respective half-reactions in Table 20.1, predict whether the following reaction is spontaneous if all the ions are 1.0 *M* at 25 °C. If it is not, write the equation that represents a spontaneous reaction.

$$\text{Ni}^{2+}(aq) + 2\text{Fe}^{2+}(aq) \longrightarrow \text{Ni}(s) + 2\text{Fe}^{3+}(aq)$$

Calculating Standard Cell Potentials

We've just seen that we can use standard reduction potentials to predict spontaneous redox reactions. If we intend to use these reactions in a galvanic cell, we can also predict what the standard cell potential will be, as illustrated in the next example.

Example 20.4

Predicting the Cell Reaction and Standard Cell Potential of a Galvanic Cell

A typical cell of a lead storage battery of the type used to start automobiles is constructed using electrodes made of lead and lead(IV) oxide (PbO_2) and with sulfuric acid as the electrolyte. The half-reactions and their standard reduction potentials in this system are

$$\text{PbO}_2(s) + 3\text{H}^+(aq) + \text{HSO}_4^-(aq) + 2e^- \rightleftharpoons \text{PbSO}_4(s) + 2\text{H}_2\text{O} \qquad E^\circ_{\text{PbO}_2} = 1.69\text{ V}$$

$$\text{PbSO}_4(s) + \text{H}^+(aq) + 2e^- \rightleftharpoons \text{Pb}(s) + \text{HSO}_4^-(aq) \qquad E^\circ_{\text{PbSO}_4} = -0.36\text{ V}$$

What is the cell reaction and what is the standard potential of this cell?

■ **Analysis:** We can easily predict spontaneous reactions if the system is at standard state. In the spontaneous cell reaction, the half-reaction with the larger (more positive) standard reduction potential will take place as reduction while the other half-reaction will be reversed and occur as oxidation.

■ **Assembling the Tools:** The standard cell potential for a spontaneous reaction is simply the difference between the two standard reduction potentials, calculated using Equation 20.2, that results in a positive number. In this example we are given the standard reduction potentials. If they were not given, we would use a table of standard reduction potentials for the needed data.

We use the methods in Section 6.2 to combine the two half-reactions, once we determine which should be the oxidation and which is the reduction, based on which standard reduction potential is more positive.

Remember that half-reactions are combined following the same procedure used in the ion–electron method of balancing redox reactions (Section 6.2).

Solution: PbO_2 has a larger, more positive standard reduction potential than $PbSO_4$, so the first half-reaction will occur in the direction written. The second must be reversed to occur as an oxidation. In the cell, therefore, the half-reactions are

$$PbO_2(s) + 3H^+(aq) + HSO_4^-(aq) + 2e^- \longrightarrow PbSO_4(s) + 2H_2O$$

$$Pb(s) + HSO_4^-(aq) \longrightarrow PbSO_4(s) + H^+(aq) + 2e^-$$

Since both half reactions have two electrons each, we can add the two half-reactions and cancel the electrons to obtain the cell reaction,

$$PbO_2(s) + Pb(s) + 2H^+(aq) + 2HSO_4^-(aq) \longrightarrow 2PbSO_4(s) + 2H_2O$$

The cell standard potential is

$$E^\circ_{\text{cell}} = (E^\circ \text{ of substance reduced}) - (E^\circ \text{ of substance oxidized})$$

Since the first half-reaction occurs as a reduction and the second as an oxidation,

$$\begin{aligned} E^\circ_{\text{cell}} &= E^\circ_{PbO_2} - E^\circ_{PbSO_4} \\ &= (1.69 \text{ V}) - (-\,0.36 \text{ V}) \\ &= 2.05 \text{ V} \end{aligned}$$

Are the Answer Reasonable? The half-reactions involved in the problem are located in Table 20.1, and their relative positions tell us that PbO_2 will be reduced and that lead will be oxidized. Therefore, we've combined the half-reactions correctly and we can feel confident that we've also applied Equation 20.2 correctly.

Example 20.5

Predicting the Cell Reaction and Standard Cell Potential of a Galvanic Cell

A galvanic cell is constructed by placing 1.0 *M* aluminum nitrate in one beaker with an aluminum electrode and a second beaker with 1.0 *M* copper nitrate and a copper electrode. When a salt bridge is inserted to connect the two beakers, what cell potential do we expect to measure between the copper and aluminum electrodes? Which electrode is the anode and what is the spontaneous chemical reaction?

Analysis: This problem is very similar to the preceding one, so we expect to proceed in essentially the same way, but we have a bit more work to do. We need to write the correct formulas, ions, and possible half-reactions that are involved. Then we will use their standard reduction potentials to make appropriate decisions to arrive at the spontaneous reaction and standard cell potential.

Assembling the Tools: We will use the information in Section 6.2 to write the half reactions for each cell (review Section 3.5 for nomenclature if necessary). Next, the principles used previously will be used to correctly determine which should be the reduction half-reaction and which the oxidation half-reaction. This will also tell us which electrode is the cathode and which is the anode. Finally, we need Equation 20.2 to determine the standard cell voltage.

Solution: First, we will write two half-reactions (in the form of reduction half-reactions) for Cu^{2+} reduced to $Cu(s)$ and for Al^{3+} reduced to $Al(s)$. Our tool for predicting spontaneous reactions indicates that the half-reaction with the more positive standard reduction potential will occur as a reduction; the other will occur as an oxidation. In this cell, then, Cu^{2+} is reduced and Al is oxidized. To obtain the cell reaction, we add the two half-reactions, remembering that the electrons must cancel. This means we must multiply the copper half-reaction by 3 and the aluminum half-reaction by 2.

$$\begin{array}{rr} 3[\mathrm{Cu}^{2+}(aq) + 2e^- \longrightarrow \mathrm{Cu}(s)] & \text{(reduction)} \\ 2[\mathrm{Al}(s) \longrightarrow \mathrm{Al}^{3+}(aq) + 3e^-] & \text{(oxidation)} \\ \hline 3\mathrm{Cu}^{2+}(aq) + 2\mathrm{Al}(s) \longrightarrow 3\mathrm{Cu}(s) + 2\mathrm{Al}^{3+}(aq) & \text{(cell reaction)} \end{array}$$

The anode in the cell is aluminum because that is where oxidation takes place (by definition).

To obtain the standard cell potential, we substitute into Equation 20.2.

$$\begin{aligned} E^\circ_{\text{cell}} &= E^\circ_{\mathrm{Cu}^{2+}} - E^\circ_{\mathrm{Al}^{3+}} \\ &= (0.34 \text{ V}) - (-1.66 \text{ V}) \\ &= 2.00 \text{ V} \end{aligned}$$

An important point to notice here is that *although we multiply the half-reactions by factors to make the electrons cancel,* ***we do not multiply the standard reduction potentials by these factors.***[3] To obtain the standard cell potential, we simply subtract one standard reduction potential from the other.

■ **Are the Answers Reasonable?** If we locate these half-reactions in Table 20.1, their relative positions tell us we've written the correct equation for the spontaneous reaction. It also means we've identified correctly the substances reduced and oxidized, so we've correctly applied Equation 20.2.

Practice Exercises

■ These are the reactions in an Edison cell, a type of rechargeable storage battery.

20.8 | What are the overall cell reaction and the standard cell potential of a galvanic cell employing the following half-reactions?

$$\begin{array}{lr} \mathrm{NiO_2}(s) + 2\mathrm{H_2O} + 2e^- \rightleftharpoons \mathrm{Ni(OH)_2}(s) + 2\mathrm{OH}^-(aq) & E^\circ_{\mathrm{NiO_2}} = 0.49 \text{ V} \\ \mathrm{Fe(OH)_2}(s) + 2e^- \rightleftharpoons \mathrm{Fe}(s) + 2\mathrm{OH}^-(aq) & E^\circ_{\mathrm{Fe(OH)_2}} = -0.88 \text{ V} \end{array}$$

(*Hint*: Recall that standard cell potentials are based on a spontaneous reaction.)

20.9 | What are the overall cell reaction and the standard cell potential of a galvanic cell employing the following half-reactions?

$$\begin{array}{lr} \mathrm{Cr}^{3+}(aq) + 3e^- \rightleftharpoons \mathrm{Cr}(s) & E^\circ_{\mathrm{Cr}^{3+}} = -0.74 \text{ V} \\ \mathrm{MnO_4}^-(aq) + 8\mathrm{H}^+(aq) + 5e^- \rightleftharpoons \mathrm{Mn}^{2+}(aq) + 4\mathrm{H_2O} & E^\circ_{\mathrm{MnO_4}^-} = +1.51 \text{ V} \end{array}$$

20.10 | A 1.0 *M* solution of copper perchlorate and 1.0 *M* chromium(III) nitrate along with some copper wire and a chunk of chromium are placed in the same beaker, at 25 °C. Write the balanced equation for the spontaneous reaction, and determine the standard cell potential if the same materials are used in a galvanic cell.

Cell Potentials of Spontaneous Reactions

Because we can predict the spontaneous redox reaction that will take place among a mixture of reactants, it also should be possible to predict whether or not a particular reaction, *as written*, can occur spontaneously. We can do this by calculating the standard cell potential that corresponds to the reaction in question and seeing if the standard potential is *positive.*

TOOLS

E°_{cell} and spontaneous reactions

> In a galvanic cell, the calculated standard cell potential for the spontaneous reaction is always positive. If the calculated standard cell potential is negative, the reaction is spontaneous in the reverse direction.

---

[3] Reduction potentials are intensive quantities; they have the units volts, which are joules *per coulomb*. The same number of joules are available for each coulomb of charge regardless of the total number of electrons shown in the equation. Therefore, reduction potentials are never multiplied by factors before they are subtracted to give the cell potential.

For example, to obtain the standard cell potential for a spontaneous reaction in our previous examples, we subtracted the standard reduction potentials in a way that gave a positive answer. Therefore, if we compute the standard cell potential for a particular reaction *based on the way the equation is written* and the standard potential comes out positive, we know the reaction is spontaneous. If the calculated standard cell potential comes out negative, however, the reaction is nonspontaneous. In fact, it is really spontaneous in the opposite direction.

Example 20.6

Determining Whether a Reaction Is Spontaneous by Using the Calculated Standard Cell Potential

Determine whether the following reactions, at standard state, are spontaneous as written. If a reaction is not spontaneous, write the equation for the reaction that is.

$$(1)\quad Cu(s) + 2H^+(aq) \longrightarrow Cu^{2+}(aq) + H_2(g)$$

$$(2)\quad 3Cu(s) + 2NO_3^-(aq) + 8H^+(aq) \longrightarrow 3Cu^{2+}(aq) + 2NO(g) + 4H_2O$$

Analysis: Our goal for each reaction will be to calculate the standard cell potential based on the reaction as written. Based on that we will determine if the reaction as written is spontaneous. If the reaction is not spontaneous, we will write the reverse reaction, which will be spontaneous.

Assembling the Tools: The algebraic sign of E°_{cell} will tell us if a reaction as written is spontaneous. To calculate E°_{cell}, we need to divide the equation into its half-reactions (Chapter 6), find the necessary standard reduction potentials in Table 20.1, and then use Equation 20.2 to calculate E°_{cell}. The signs of E°_{cell} will then tell us whether or not the reactions are spontaneous as written under standard conditions.

Solution: (1) The half-reactions involved in this equation are

$$\begin{aligned} Cu(s) &\longrightarrow Cu^{2+}(aq) + 2e^- &&\text{(oxidation)} \\ 2H^+(aq) + 2e^- &\longrightarrow H_2(g) &&\text{(reduction)} \end{aligned}$$

The H^+ is reduced and Cu is oxidized, so Equation 20.2 will take the form

$$E^\circ_{\text{cell}} = \underbrace{E^\circ_{H^+}}_{\substack{\text{Standard reduction}\\ \text{potential of substance}\\ \text{reduced}}} - \underbrace{E^\circ_{Cu^{2+}}}_{\substack{\text{Standard reduction}\\ \text{potential of substance}\\ \text{oxidized}}}$$

Substituting values from Table 20.1 gives

$$\begin{aligned} E^\circ_{\text{cell}} &= (0.00\text{ V}) - (0.34\text{ V}) \\ &= -0.34\text{ V} \end{aligned}$$

The calculated standard cell potential is negative, so reaction (1) is not spontaneous in the forward direction. The spontaneous reaction is actually the reverse of (1).

$$\underbrace{Cu^{2+}(aq) + H_2(g) \longrightarrow Cu(s) + 2H^+(aq)}_{\text{Reaction (1) reversed}}$$

(2) The half-reactions involved in this equation are

$$\begin{aligned} Cu(s) &\longrightarrow Cu^{2+}(aq) + 2e^- \\ NO_3^-(aq) + 4H^+(aq) + 3e^- &\longrightarrow NO(g) + 2H_2O \end{aligned}$$

The Cu is oxidized while the NO_3^- is reduced. According to Equation 20.2,

$$E^\circ_{\text{cell}} = E^\circ_{NO_3^-} - E^\circ_{Cu^{2+}}$$

Substituting values from Table 20.1 gives

$$\begin{aligned} E^\circ_{\text{cell}} &= (0.96\ \text{V}) - (0.34\ \text{V}) \\ &= +0.62\ \text{V} \end{aligned}$$

■ Copper dissolves in HNO_3 because it contains the oxidizing agent NO_3^-.

Because the calculated standard cell potential is positive, reaction (2) is spontaneous in the forward direction, as written.

■ **Are the Answers Reasonable?** By noting the relative positions of the half-reactions in Table 20.1, you can confirm that we've answered the questions correctly.

Practice Exercises

20.11 | Write each of the following equations so that they represent spontaneous reactions at standard state.

(a) $Br_2(aq) + 2I^-(aq) \longrightarrow 2Br^-(aq) + I_2(s)$

(b) $MnO_4^-(aq) + 5Ag(s) + 8H^+(aq) \longrightarrow Mn^{2+}(aq) + 5Ag^+(aq) + 4H_2O$

(*Hint:* Determine the sign of the calculated standard cell potential.)

20.12 | Under standard state conditions, which of the following reactions occur spontaneously? Justify your answer.

(a) $Br_2(aq) + Cl_2(g) + 2H_2O \longrightarrow 2Br^-(aq) + 2HOCl(aq) + 2H^+(aq)$

(b) $3Zn(s) + 2Cr^{3+}(aq) \longrightarrow 3Zn^{2+}(aq) + 2Cr(s)$

In the previous examples and exercises we have been rigorous in specifying that standard reduction potentials are used when the system is at standard state. If the cell is not at standard state, the numerical value of the cell potential, E_{cell}, will not be the same as the standard cell potential, but in the majority of cases, the algebraic sign of E_{cell} will be the same and we can reach the same conclusions about spontaneity. We will consider methods for computing E_{cell} in Section 20.5.

20.4 | E°_{cell} and ΔG°

The fact that cell potentials allow us to predict the spontaneity of redox reactions is no coincidence. There is a relationship between the cell potential and the free energy change for a reaction. In Chapter 19, we saw that ΔG for a reaction is a measure of the maximum useful work that can be obtained from a chemical reaction. Specifically, the relationship is

$$-\Delta G = \text{maximum work} \qquad \textbf{(20.3)}$$

In an electrical system, work is supplied by the flow of electric charge created by the potential of the cell. It can be calculated from the equation

TOOLS

Faraday constant

$$\text{maximum work} = n\mathcal{F}E_{\text{cell}} \qquad \textbf{(20.4)}$$

■ More precisely, 1 $\mathcal{F}$ = 96,485 C.

where n is the number of moles of electrons transferred, $\mathcal{F}$ is a constant called the **Faraday constant,** which is equal to the number of coulombs of charge equivalent to 1 mol of electrons (9.65×10^4 coulombs per mole of electrons), and E_{cell} is the potential of the cell in volts. To see that Equation 20.4 gives work (which has the units of energy) we can analyze the units. In Equation 20.1 you saw that 1 volt = 1 joule/coulomb. Therefore,

$$\text{maximum work} = \underset{\underset{n}{\Updownarrow}}{\cancel{\text{mole}}\ \text{e}^-} \times \underset{\underset{\mathscr{F}}{\Updownarrow}}{\left(\frac{\cancel{\text{coulombs}}}{\cancel{\text{mole}}\ \text{e}^-}\right)} \times \underset{\underset{E_{\text{cell}}}{\Updownarrow}}{\left(\frac{\text{joule}}{\cancel{\text{coulombs}}}\right)} = \text{joule}$$

Combining Equations 20.3 and 20.4 gives us

$$\Delta G = -n\mathscr{F}E_{\text{cell}} \qquad \textbf{(20.5)}$$

TOOLS ΔG related to E_{cell}

At standard state we are dealing with the *standard* cell potential, so we can calculate the *standard* free energy change.

$$\Delta G^\circ = -n\mathscr{F}E^\circ_{\text{cell}} \qquad \textbf{(20.6)}$$

TOOLS ΔG° related to E°_{cell}

Referring back to Chapter 19, if ΔG has a negative value, a reaction will be spontaneous, and this corresponds to a positive value of E_{cell}.

Up to now we have been careful to predict spontaneity for systems at standard state where E_{cell} is equal to E°_{cell}. Later in Section 20.5, we will see how to calculate E_{cell} under nonstandard state conditions and precisely predict if a reaction is spontaneous.

Example 20.7
Calculating the Standard Free Energy Change

Calculate ΔG° for the following reaction, given that its standard cell potential is 0.320 V at 25 °C.

$$\text{NiO}_2(s) + 2\text{Cl}^-(aq) + 4\text{H}^+(aq) \longrightarrow \text{Cl}_2(g) + \text{Ni}^{2+}(aq) + 2\text{H}_2\text{O}$$

■ **Analysis:** We will need to use the relationship between E°_{cell} and ΔG°. The given chemical equation allows us to determine *n,* which is used in the equation.

■ **Assembling the Tools:** Our tool for solving this problem is Equation 20.6.

$$\Delta G^\circ = -n\mathscr{F}E^\circ_{\text{cell}}$$

We know $\mathscr{F}$ and E°_{cell}, and the value of *n,* the total number of electrons transferred in the balanced chemical equation, can be computed with the aid of principles developed in Section 6.2. We will also use the Faraday constant, 1 $\mathscr{F} = 9.65 \times 10^4$ C/mol e^- (the SI abbreviation for coulomb is C).

$$1\,\mathscr{F} = \left(\frac{9.65 \times 10^4\ \text{C}}{1\ \text{mol}\ e^-}\right)$$

■ **Solution:** To solve Equation 20.6 we need to determine *n*. By taking the coefficients in the chemical equation to stand for *moles,* two moles of Cl$^-$ are oxidized to Cl$_2$ and two moles of electrons are transferred to the NiO$_2$. Therefore we conclude that $n = 2$ mol e^-. Using Equation 20.6, we have

$$\begin{aligned}\Delta G^\circ &= -(2\ \cancel{\text{mol}\ e^-}) \times \left(\frac{9.65 \times 10^4\ \cancel{\text{C}}}{1\ \cancel{\text{mol}\ e^-}}\right) \times \left(\frac{0.320\ \text{J}}{\cancel{\text{C}}}\right)\\ &= -6.18 \times 10^4\ \text{J}\\ &= -61.8\ \text{kJ}\end{aligned}$$

■ **Is the Answer Reasonable?** Let's do some approximate arithmetic. The Faraday constant equals approximately 100,000, or 10^5. The product $2 \times 0.32 = 0.64$, so ΔG° should be about 0.64×10^5 or 6.4×10^4. The answer seems to be okay. Importantly, the algebraic signs tell us the same thing: that is, the positive E°_{cell} and the negative ΔG° both predict a spontaneous reaction.

Practice Exercises

20.13 | A certain reaction has an E°_{cell} of 0.107 volts and has a ΔG° of -30.9 kJ. How many electrons are transferred in the reaction? (*Hint*: See Equation 20.6.)

20.14 | Calculate ΔG° for the reactions that take place in the galvanic cells described in Practice Exercises 20.11 and 20.12.

E°_{cell} and Equilibrium Constants

One of the useful applications of electrochemistry is the determination of equilibrium constants. In Chapter 19 you saw that ΔG° is related to the equilibrium constant by the expression

$$\Delta G^\circ = -RT \ln K_c$$

where we used K_c for the equilibrium constant because electrochemical reactions occur in solution. Earlier in this section we saw that ΔG° is also related to E°_{cell}

$$\Delta G^\circ = -n \mathscr{F} E^\circ_{\text{cell}}$$

Therefore, E°_{cell} and the equilibrium constant are also related. Equating the right sides of the two equations, we have

$$-n \mathscr{F} E^\circ_{\text{cell}} = -RT \ln K_c$$

Solving for E°_{cell} gives[4]

TOOLS

K_c related to E°_{cell}

$$E^\circ_{\text{cell}} = \frac{RT}{n\mathscr{F}} \ln K_c \qquad (20.7)$$

For the units to work out correctly, the value of R must be 8.314 J mol^{-1} K^{-1}, T must be the temperature in kelvins, $\mathscr{F}$ equals 9.65×10^4 C per mole of e^-, and n equals the number of moles of electrons transferred in the reaction.

Example 20.8

Calculating Equilibrium Constants from E°_{cell}

Calculate K_c for the reaction in Example 20.7.

■ **Analysis:** We now have an equation that relates the standard cell potential and the equilibrium constant. We need to choose the appropriate values for each variable to determine K_c.

■ **Assembling the Tools:** Equation 20.7 is our tool for solving this problem. We need to collect the terms to insert in this equation to solve it. We need to find E°_{cell}, n, R, T, and $\mathscr{F}$. Remember that T is in kelvins and R must have the appropriate units of J mol^{-1} K^{-1}. Collecting the values needed, we find:

$T = 25\ ^\circ\text{C} = 298$ K

$E^\circ_{\text{cell}} = 0.320 \text{ V} = 0.320 \text{ J C}^{-1}$

$\mathscr{F} = 9.65 \times 10^4$ C per mole of e^-

$n = 2$

$R = 8.314$ J mol^{-1} K^{-1}

---

[4] For historical reasons, Equation 20.7 is sometimes expressed in terms of common logs (base 10 logarithms). Natural and common logarithms are related by the equation

$$\ln x = 2.303 \log x$$

For reactions at 25 °C (298 K), all of the constants (R, T, and $\mathscr{F}$) can be combined with the factor 2.303 to give 0.0592 joules/coulomb. Because joules/coulomb equals volts, Equation 20.7 reduces to

$$E^\circ_{\text{cell}} = \frac{0.0592 \text{ V}}{n} \log K_c$$

where n is the number of moles of electrons transferred in the cell reaction as it is written.

Solution: With all of the data, let's rearrange Equation 20.7 for ln K_c and then substitute values.

$$\ln K_c = \frac{E^\circ_{\text{cell}}\, n\, \mathcal{F}}{RT}$$

Substituting values,

$$\begin{aligned}\ln K_c &= \frac{0.320\ \cancel{\text{J}}\ \cancel{\text{C}^{-1}} \times 2 \times 9.65 \times 10^4\ \cancel{\text{C}}\ \cancel{\text{mol}^{-1}}}{8.314\ \cancel{\text{J}}\ \cancel{\text{mol}^{-1}}\ \cancel{\text{K}^{-1}} \times 298\ \cancel{\text{K}}} \\ &= 24.9\end{aligned}$$

Taking the antilogarithm,

$$K_c = e^{24.9} = 7 \times 10^{10}$$

Is the Answer Reasonable? As a rough check, we can look at the magnitude of E°_{cell} and apply some simple reasoning. When E°_{cell} is positive, ΔG° is negative, and in Chapter 19 you learned that when ΔG° is negative, the position of equilibrium lies toward the product side of the reaction. Therefore, we expect that K_c will be large, and that agrees with our answer.

A more complete check would require evaluating the fraction used to compute ln K_c. First, we should check to be sure we've substituted correctly into the equation for ln K_c. Next, we could do some approximate arithmetic to check the value of ln K_c. Rounding all numbers to one significant figure we get:

$$\ln K_c = \frac{0.3\ \cancel{\text{J}}\ \cancel{\text{C}^{-1}} \times 2 \times 10 \times 10^4\ \cancel{\text{C}}\ \cancel{\text{mol}^{-1}}}{10\ \cancel{\text{J}}\ \cancel{\text{mol}^{-1}}\ \cancel{\text{K}^{-1}} \times 300\ \cancel{\text{K}}} = \frac{6 \times 10^4}{3000} = 2 \times 10^1 = 20$$

This is close to the 24.9 we calculated above, and we are confident the calculation was done correctly.

Practice Exercises

20.15 | The calculated standard cell potential for the reaction

$$\text{Cu}^{2+}(aq) + 2\text{Ag}(s) \rightleftharpoons \text{Cu}(s) + 2\text{Ag}^+(aq)$$

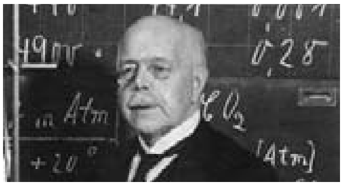
is $E^\circ_{\text{cell}} = -0.46$ V. Calculate K_c for this reaction as written. Is this reaction spontaneous? If not, what is K_c for the spontaneous reaction? (*Hint*: The tool described by Equation 20.7 is important here.)

20.16 | Use the following half-reactions and the data in Table 20.1 to write the spontaneous reaction. Write the equilibrium law for this reaction and use the standard cell voltage to determine the value of the equilibrium constant.

$$\begin{aligned}\text{Ag}^+(aq) + e^- &\longrightarrow \text{Ag}(s) \\ \text{AgBr}(s) + e^- &\longrightarrow \text{Ag}(s) + \text{Br}^-(aq)\end{aligned}$$

20.5 | Cell Potentials and Concentrations

At 25 °C when all of the ion concentrations in a cell are 1.00 *M* and when the partial pressures of any gases involved in the cell reaction are 1.00 atm, the cell potential is equal to the standard potential. When the concentrations or pressures change, however, so does the potential. For example, in an operating cell or battery, the potential gradually drops as the reactants are used up and as the cell reaction approaches its natural equilibrium status. When it reaches equilibrium, the potential has dropped to zero—the battery is "dead".



Walther Nernst (1864–1941) was a professor of physical chemistry who developed the equation named after him. *(Ullstein Bild/The Granger Collection, New York)*

TOOLS

Nernst equation

The Nernst Equation

The effect of concentration on the cell potential can be obtained from thermodynamics. In Chapter 19, you learned that the free energy change is related to the reaction quotient Q by the equation

$$\Delta G = \Delta G^\circ + RT \ln Q$$

Substituting for ΔG and ΔG° from Equations 20.5 and 20.6 gives

$$-n\mathcal{F}E_{\text{cell}} = -n\mathcal{F}E^\circ_{\text{cell}} + RT \ln Q$$

Dividing both sides by $-n\mathcal{F}$ gives

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{RT}{n\mathcal{F}} \ln Q \tag{20.8}$$

This equation is commonly known as the **Nernst equation,**[5] named after Walther Nernst, a German chemist and physicist. Notice that if $Q = 1$, then $\ln Q = 0$ and $E_{\text{cell}} = E^\circ_{\text{cell}}$.

In writing the Nernst equation for a galvanic cell, we will construct the mass action expression (from which we calculate the value of Q) using molar concentrations for ions and partial pressures in atmospheres for gases.[6] Thus, for the following cell using a hydrogen electrode (with the partial pressure of H_2 not necessarily equal to 1 atm) and having the reaction

■ This is a heterogeneous reaction, so we have not included the concentration of the solid, Cu(*s*), in the mass action expression.

$$\text{Cu}^{2+}(aq) + \text{H}_2(g) \longrightarrow \text{Cu}(s) + 2\text{H}^+(aq)$$

the Nernst equation would be written

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{RT}{n\mathcal{F}} \ln \frac{[\text{H}^+]^2}{[\text{Cu}^{2+}]\,P_{\text{H}_2}}$$

Example 20.9
Calculating the Effect of Concentration on E_{cell}

Suppose a galvanic cell employs the following half-reactions.

$$\text{Ni}^{2+}(aq) + 2e^- \rightleftharpoons \text{Ni}(s) \qquad E^\circ_{\text{Ni}^{2+}} = -0.25\text{ V}$$
$$\text{Cr}^{3+}(aq) + 3e^- \rightleftharpoons \text{Cr}(s) \qquad E^\circ_{\text{Cr}^{3+}} = -0.74\text{ V}$$

Calculate the cell potential when $[\text{Ni}^{2+}] = 4.87 \times 10^{-4}\ M$ and $[\text{Cr}^{3+}] = 2.48 \times 10^{-3}\ M$.

■ **Analysis:** We will be calculating the cell potential for a system that does not have standard state concentrations by using the Nernst equation. As with previous problems, we will need to write the appropriate chemical equations so that the variables can be identified and used properly.

■ **Assembling the Tools:** We start with the Nernst equation, Equation 20.8, to determine E_{cell}.

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{RT}{n\mathcal{F}} \ln Q$$

---

[5] Using common logarithms instead of natural logarithms and calculating the constants for 25 °C gives another form of the Nernst equation that is sometimes used:

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0592\text{ V}}{n} \log Q$$

[6] Because of interionic attractions, ions do not always behave as though their concentrations are equal to their molarities. Strictly speaking, therefore, we should use effective concentrations (called activities) in the mass action expression. Effective concentrations are difficult to calculate, so for simplicity we will use molarities and accept the fact that our calculations are not entirely accurate.

The balanced chemical equation is needed (Chapter 6) to determine the number of electrons transferred, *n*, and the correct form of the mass action expression (Chapter 15) from which we calculate the value of *Q*.

Solution: Nickel has the more positive (less negative) standard reduction potential, so its half-reaction will occur as a reduction. This means that chromium will be oxidized. Making electron gain ($6e^-$) equal to electron loss ($6e^-$), the cell reaction is found as follows.

$$\begin{array}{rr} 3[\mathrm{Ni}^{2+}(aq) + 2e^- \longrightarrow \mathrm{Ni}(s)] & \text{(reduction)} \\ 2[\mathrm{Cr}(s) \longrightarrow \mathrm{Cr}^{3+}(aq) + 3e^-] & \text{(oxidation)} \\ \hline 3\mathrm{Ni}^{2+}(aq) + 2\mathrm{Cr}(s) \longrightarrow 3\mathrm{Ni}(s) + 2\mathrm{Cr}^{3+}(aq) & \text{(cell reaction)} \end{array}$$

The total number of electrons transferred is six, which means $n = 6$. Now we can write the Nernst equation for the system.

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{RT}{n\mathscr{F}} \ln \frac{[\mathrm{Cr}^{3+}]^2}{[\mathrm{Ni}^{2+}]^3}$$

Notice that we've constructed the mass action expression, from which we will calculate the reaction quotient, using the concentrations of the ions raised to powers equal to their coefficients in the net cell reaction, and that we have not included concentration terms for the two solids. This is the procedure we followed for heterogeneous equilibria in Section 15.4.

Next we need E°_{cell}. Since Ni^{2+} is reduced,

$$\begin{aligned} E^\circ_{\text{cell}} &= E^\circ_{\mathrm{Ni}^{2+}} - E^\circ_{\mathrm{Cr}^{3+}} \\ &= (-0.25\ \mathrm{V}) - (-0.74\ \mathrm{V}) \\ &= 0.49\ \mathrm{V} \end{aligned}$$

Now we can substitute this value for E°_{cell} along with $R = 8.314\ \mathrm{J\ mol^{-1}\ K^{-1}}$, $T = 298\ \mathrm{K}$, $n = 6$, $\mathscr{F} = 9.65 \times 10^4\ \mathrm{C\ mol^{-1}}$, $[\mathrm{Ni}^{2+}] = 4.87 \times 10^{-4}\ M$, and $[\mathrm{Cr}^{3+}] = 2.48 \times 10^{-3}\ M$ into the Nernst equation. This gives

$$E_{\text{cell}} = 0.49\ \mathrm{V} - \frac{8.314\ \mathrm{J}\ \cancel{\mathrm{mol}^{-1}}\ \cancel{\mathrm{K}^{-1}} \times 298\ \cancel{\mathrm{K}}}{6 \times (9.65 \times 10^4\ \mathrm{C}\ \cancel{\mathrm{mol}^{-1}})} \ln \frac{(2.48 \times 10^{-3})^2}{(4.87 \times 10^{-4})^3}$$

We notice that the volt, V, is 1 J/C so that we obtain

$$\begin{aligned} E_{\text{cell}} &= 0.49\ \mathrm{V} - (0.00428\ \mathrm{V}) \ln (5.32 \times 10^4) \\ &= 0.49\ \mathrm{V} - (0.00428\ \mathrm{V})\,(10.882) \\ &= 0.49\ \mathrm{V} - 0.0525\ \mathrm{V} \\ &= 0.44\ \mathrm{V} \end{aligned}$$

The potential of the cell is expected to be 0.44 V.

Is the Answer Reasonable? There's no simple way to check the answer, but the small numerical value of 0.44 V is reasonable. In addition, there are certain important points to consider. First, check that you've combined the half-reactions correctly to (a) calculate E°_{cell} and (b) give the balanced cell reaction. Now check that we wrote the correct mass action expression from the balanced equation and that we have the correct number of electrons transferred, *n*. Finally, check that the Kelvin temperature and $R = 8.314\ \mathrm{J\ mol^{-1}\ K^{-1}}$ were used.

Example 20.10

The Spontaneous Reaction May Be Concentration Dependent

The reaction of tin metal with acid can be written as

$$\mathrm{Sn}(s) + 2\mathrm{H}^+(aq) \longrightarrow \mathrm{Sn}^{2+}(aq) + \mathrm{H}_2(g)$$

Calculate the cell potential when (a) the system is at standard state, (b) the pH is 2.00, and (c) the pH is 5.00. Assume that $[\mathrm{Sn}^{2+}] = 1.0\ M$ and the partial pressure of H_2 is 1.00 atm.

■ Analysis: We will be using the equations developed in this chapter for computing the values for the standard cell potential and various cell potentials. For this we will need to identify the substances that are oxidized and reduced in a chemical reaction and gather the information needed to solve the appropriate equations. One way to approach this problem is to write out the equations and then find values for the variables.

■ Assembling the Tools: Part (a) is at standard state, and we have used Equation 20.2 for combining standard reduction potentials to solve problems like that in Examples 20.5 and 20.6. In this reaction we identify the tin metal as the substance that is oxidized and hydrogen ions are reduced.

For parts (b) and (c) we must use the Nernst equation as our tool, Equation 20.8. We determine the number of electrons transferred, n, by noting that tin loses two electrons and each hydrogen gains an electron. Therefore two electrons are transferred from tin to the hydrogen ions. We can also set up Q, see Chapter 15, for the Nernst equation. Substituting 1.00 for both $[\mathrm{Sn}^{2+}]$ and P_{H_2}, the result is

$$Q = \frac{[\mathrm{Sn}^{2+}]\,P_{\mathrm{H}_2}}{[\mathrm{H}^+]^2} = \frac{1}{[\mathrm{H}^+]^2}$$

We can also calculate the hydrogen ion concentrations for the pH 2.00 and pH 5.00 solutions as $1.0 \times 10^{-2}\ M$ and $1.0 \times 10^{-5}\ M$, respectively.

■ Solution: For part (a) we find the difference between standard reduction potentials as

$$E^\circ_{\mathrm{cell}} = 0.00 - (-0.14) = +0.14\ \mathrm{V}$$

For parts (b) and (c) we substitute into the Nernst equation

$$E_{\mathrm{cell}} = E^\circ_{\mathrm{cell}} - \frac{RT}{n\mathscr{F}} \ln \frac{1}{[\mathrm{H}^+]^2}$$

$$\text{(b) } E_{\mathrm{cell}} = 0.14\ \mathrm{V} - \frac{8.314\ \mathrm{J}\ \cancel{\mathrm{mol}^{-1}}\ \cancel{\mathrm{K}^{-1}} \times 298\ \cancel{\mathrm{K}}}{2 \times (9.65 \times 10^4\ \mathrm{C}\ \cancel{\mathrm{mol}^{-1}})} \ln \frac{1}{(1.0 \times 10^{-2})^2}$$

$$E_{\mathrm{cell}} = 0.14\ \mathrm{V} - 0.12 = +0.02\ \mathrm{V}$$

$$\text{(c) } E_{\mathrm{cell}} = 0.14\ \mathrm{V} - \frac{8.314\ \mathrm{J}\ \cancel{\mathrm{mol}^{-1}}\ \cancel{\mathrm{K}^{-1}} \times 298\ \cancel{\mathrm{K}}}{2 \times (9.65 \times 10^4\ \mathrm{C}\ \cancel{\mathrm{mol}^{-1}})} \ln \frac{1}{(1.0 \times 10^{-5})^2}$$

$$E_{\mathrm{cell}} = 0.14\ \mathrm{V} - 0.30 = -0.16\ \mathrm{V}$$

At standard state the reaction is spontaneous, and at pH = 2.00 it is spontaneous, but the potential is barely positive. At pH 5.00 the reaction is not spontaneous, but the reverse reaction will be.

■ Is the Answer Reasonable? The first question to answer is "does this make sense?" and indeed it does. Looking at the natural logarithm part of the equation we see that as the $[\mathrm{H}^+]$ decreases, the ln term increases and makes a more negative adjustment to the E°_{cell}. Since a decrease in $[\mathrm{H}^+]$ is an increase in pH, we expect E_{cell} will decrease as pH increases. We cannot easily estimate natural logarithms, so a check of calculations may be easiest if the values are entered into your calculator in a different sequence from your first calculation.

Practice Exercises

20.17 | A galvanic cell is constructed with a copper electrode dipping into a 0.015 M solution of Cu^{2+} ions and an electrode made of magnesium is immersed in a $2.2 \times 10^{-6}\ M$ solution of magnesium ions. What is the balanced chemical equation and the cell potential at 25 °C? (*Hint*: Set up the Nernst equation for this reaction.)

20.18 | In Example 20.10, assume all conditions are the same except for the pH. At what pH will the cell potential be zero?

20.19 | In a certain zinc–copper cell,

$$\mathrm{Zn}(s) + \mathrm{Cu}^{2+}(aq) \longrightarrow \mathrm{Zn}^{2+}(aq) + \mathrm{Cu}(s)$$

the ion concentrations are $[\mathrm{Cu}^{2+}] = 0.0100\ M$ and $[\mathrm{Zn}^{2+}] = 1.0\ M$. What is the cell potential at 25 °C?

Concentration from E_{cell} Measurements

One of the principal uses of the relationship between concentration and cell potential is for the measurement of concentrations of redox reactants and products in a galvanic cell. Experimental determination of cell potentials combined with modern developments in electronics has provided a means of monitoring and analyzing the concentrations of all sorts of substances in solution, even some that are not themselves ionic and that are not involved directly in electrochemical changes. In fact, the operation of a pH meter relies on the logarithmic relationship between hydrogen ion concentration and the potential of a special kind of electrode (Figure 20.8).

■ The ease of such operations and the fact that they lend themselves well to automation and computer analysis make electrochemical analyses especially attractive to scientists.

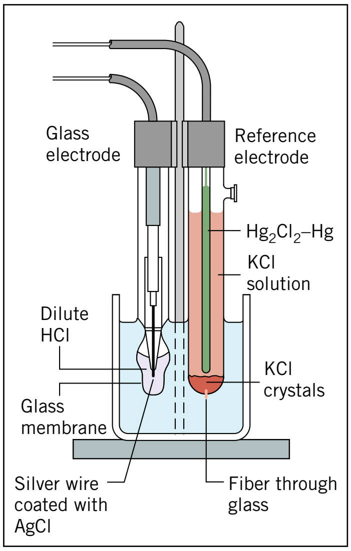


Figure 20.8 | **Electrodes used with a pH meter.** The electrode on the left is called a *glass electrode*. It contains a silver wire, coated with AgCl, dipping into a dilute solution of HCl. This half-cell has a potential that depends on the difference between the $[H^+]$ inside and outside a thin glass membrane at the bottom of the electrode. On the right is a reference electrode that forms the other half-cell. The galvanic cell formed by the two electrodes produces a potential that is proportional to the pH of the solution into which they are dipped.

Example 20.11

Using the Nernst Equation to Determine Concentrations

A laboratory was assigned the job of determining the copper(II) ion concentration in thousands of water samples. To make these measurements an electrochemical cell was assembled that consists of a silver electrode, dipping into a 0.225 M solution of $AgNO_3$, connected by a salt bridge to a second half-cell containing a copper electrode. The copper half-cell was then filled with one water sample after another, with the cell potential measured for each sample. In the analysis of one sample, the cell potential at 25 °C was measured to be 0.62 V. The copper electrode was observed to carry a negative charge, so it served as the anode. What was the concentration of copper ion in this sample?

■ **Analysis:** In this problem, we've been given the cell potential, E_{cell}, and we can calculate E°_{cell}. The unknown quantity is one of the concentration terms in Q that is part of the Nernst equation. Once we assemble all of the variables for the Nernst equation, an algebraic solution is possible.

■ **Assembling the Tools:** We will need Equation 20.8, the Nernst equation, and the chemical reaction represented by the description of the galvanic cell. Because copper is the anode, it is being oxidized. This also means that Ag^+ is being reduced. Therefore, the equation for the cell reaction is

$$Cu(s) + 2Ag^+(aq) \longrightarrow Cu^{2+}(aq) + 2Ag(s)$$

From the balanced equation we can determine the mass action expression, n, and E°_{cell}. Since R and Faraday's constant are known, along with the concentration of silver ions, the remaining variable is $[Cu^{2+}]$ that the question asks us to compute.

Solution: Two electrons are transferred, so $n = 2$ and the Nernst equation is

$$E_{\text{cell}} = E^{\circ}_{\text{cell}} - \frac{RT}{2\,\mathcal{F}} \ln \frac{[\text{Cu}^{2+}]}{[\text{Ag}^{+}]^2}$$

The value of E°_{cell} can be obtained from the tabulated standard reduction potentials in Table 20.1. Following our usual procedure and recognizing that silver ion is reduced,

$$\begin{aligned} E^{\circ}_{\text{cell}} &= E^{\circ}_{\text{Ag}^{+}} - E^{\circ}_{\text{Cu}^{2+}} \\ &= (0.80\ \text{V}) - (0.34\ \text{V}) \\ &= 0.46\ \text{V} \end{aligned}$$

Now we can substitute values into the Nernst equation and solve for the concentration ratio in the mass action expression.

$$0.62\ \text{V} = 0.46\ \text{V} - \frac{8.314\ \text{J}\ \cancel{\text{mol}^{-1}}\ \cancel{\text{K}^{-1}} \times 298\ \cancel{\text{K}}}{2 \times \left(9.65 \times 10^{4}\ \text{C}\ \cancel{\text{mol}^{-1}}\right)} \ln \frac{[\text{Cu}^{2+}]}{[\text{Ag}^{+}]^2}$$

Solving for ln $([\text{Cu}^{2+}]/[\text{Ag}^{+}]^2)$ gives (retaining one extra significant figure)

$$\ln \frac{[\text{Cu}^{2+}]}{[\text{Ag}^{+}]^2} = -12.5$$

Taking the antilog gives us the value of the mass action expression.

$$\frac{[\text{Cu}^{2+}]}{[\text{Ag}^{+}]^2} = 4 \times 10^{-6}$$

Since we know that the concentration of Ag^{+} is 0.225 *M*, we can now solve for the Cu^{2+} concentration.

$$\frac{[\text{Cu}^{2+}]}{(0.225)^2} = 4 \times 10^{-6}$$

$$[\text{Cu}^{2+}] = 2 \times 10^{-7}\ M \quad \text{(correctly rounded)}$$

Is the Answer Reasonable? All we can do easily is check to be sure we've written the correct chemical equation, on which all the rest of the solution to the problem rests. Be careful about algebraic signs and that you select the proper value for *R* and the temperature in kelvins. Also, notice that we first solved for the logarithm of the ratio of concentration terms. Then, after taking the (natural) antilogarithm, we substitute the known value for $[\text{Ag}^{+}]$ and solve for $[\text{Cu}^{2+}]$.

As a final point, notice that the Cu^{2+} concentration is indeed very small, and that it can be obtained very easily by simply measuring the potential generated by the electrochemical cell. Determining the concentrations in many samples is also very simple—just change the water sample and measure the potential again.

Practice Exercises

20.20 | A galvanic cell is constructed with a copper electrode dipping into a 0.015 *M* solution of Cu^{2+} ions, and a magnesium electrode immersed in a solution with an unknown concentration of magnesium ions. The cell potential is measured as 2.79 volts at 25 °C. What is the concentration of magnesium ions?

$$\text{Mg}(s) + \text{Cu}^{2+}(aq) \longrightarrow \text{Mg}^{2+}(aq) + \text{Cu}(s)$$

(*Hint:* Use the Nernst equation to solve for $[\text{Mg}^{2+}]$.)

20.21 | In the analysis of two other water samples by the procedure described in Example 20.11, cell potentials (E_{cell}) of 0.57 V and 0.82 V were obtained. Calculate the Cu^{2+} ion concentration in each of these samples.

20.22 | A galvanic cell was constructed with a nickel electrode that was dipped into 1.20 *M* NiSO_4 solution and a chromium electrode that was immersed into a solution containing Cr^{3+} at an unknown concentration. The potential of the cell was measured to be 0.552 V, with the chromium serving as the anode. The standard cell potential for this system was determined to be 0.487 V. What was the concentration of Cr^{3+} in the solution of unknown concentration?

Concentration Cells

The dependence of cell potential on concentration allows us to construct a galvanic cell from two half-cells composed of the same substances, but having different concentrations of the solute species. An example would be a pair of copper electrodes dipping into solutions that have different concentrations of Cu^{2+}, say 0.10 *M* Cu^{2+} in one and 1.0 *M* in the other (Figure 20.9). When this cell operates, reactions take place that tend to bring the two Cu^{2+} concentrations toward the same value. Thus, in the half-cell containing 0.10 *M* Cu^{2+}, copper is oxidized, which adds Cu^{2+} to the more dilute solution. In the other cell, Cu^{2+} is reduced, removing Cu^{2+} from the more concentrated solution. This makes the more dilute half-cell the anode and the more concentrated half-cell the cathode.

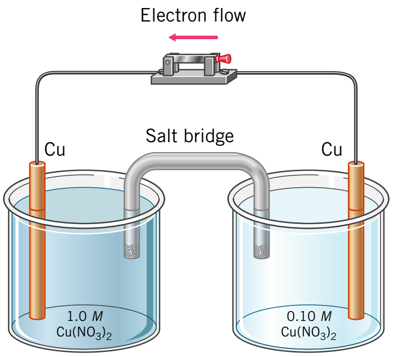

Figure 20.9 | **A concentration cell.** When the circuit is completed, reactions occur that tend to make the concentrations of Cu^{2+} the same in the two half-cells. Oxidation occurs in the more dilute half-cell, and reduction occurs in the more concentrated one.

$$\underset{\text{anode}}{Cu(s) \mid Cu^{2+}(0.10\ M)} \;\|\; \underset{\text{cathode}}{Cu^{2+}(1.0\ M) \mid Cu(s)}$$

The half-reactions in the spontaneous cell reaction are

$$\begin{array}{r} Cu(s) \longrightarrow Cu^{2+}(0.10\ M) + 2e^- \\ Cu^{2+}(1.0\ M) + 2e^- \longrightarrow Cu(s) \\ \hline Cu^{2+}(1.0\ M) \longrightarrow Cu^{2+}(0.10\ M) \end{array}$$

The Nernst equation for this cell is

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{RT}{n\mathscr{F}} \ln \frac{[Cu^{2+}]_{\text{dilute}}}{[Cu^{2+}]_{\text{conc}}}$$

Because we're dealing with the same substances in the cell, $E^\circ_{\text{cell}} = 0$ V. When the cell operates, $n = 2$, and we'll take $T = 298$ K. Substituting values,

$$\begin{aligned} E_{\text{cell}} &= 0\ \text{V} - \frac{8.314\ \text{J}\ \cancel{\text{mol}^{-1}}\ \cancel{\text{K}^{-1}} \times 298\ \cancel{\text{K}}}{2 \times 9.65 \times 10^4\ \text{C}\ \cancel{\text{mol}^{-1}}} \ln\left(\frac{0.10}{1.0}\right) \\ &= 0.030\ \text{V} \end{aligned}$$

In this concentration cell, one solution is ten times more concentrated than the other, yet the potential generated is only 0.03 V. In general, the potential generated by concentration differences are quite small. Yet they are significant in biological systems, where electrical potentials are generated across biological membranes by differences in ion concentrations (e.g., K^+). Membrane potentials are important in processes such as the transmission of nerve impulses.

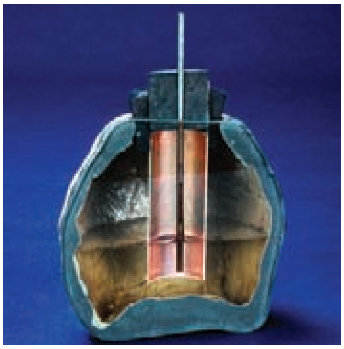
These small differences in potential also illustrate that if *Q*, in a system that is not at standard state, is between 0.10 and 10 we can conclude that $E_{\text{cell}} \approx E^\circ_{\text{cell}}$ and we can generalize the results in Sections 20.2 and 20.3 when predicting spontaneous reactions.

20.6 | Electricity

Large amounts of electricity are generated mechanically by rotating coils of wire in a magnetic field in a turbine. To rotate the coils, superheated steam, flowing water, and the wind are used in a variety of turbine designs. Superheated steam is produced reliably by burning coal, oil, natural gas, and even municipal wastes. Such turbines are used mainly in large central electrical generators near major population centers. Since the energy of the fuel is not completely converted into electricity, the efficiency of these generators ranges from 35 to 45% and they require a significant investment in pollution control.

Hydroelectric power plants are claimed to have efficiencies around 90%. They are clean and non-polluting. However, hydroelectric power often requires building large dams to maintain a reservoir of water. Additionally they are often located large distances from their customers, and transmission of electricity over long distances incurs significant losses. Wind powered turbines and wind mills are also considered to be clean and non-polluting. They are approximately 50% efficient and can be located very close to the end-user. However, daily, even hourly, fluctuations in wind speed may introduce inconvenient variations in power production.

Chemical research is important in producing new turbine materials and combustion processes to increase efficiencies of major electric generators. In this section we will concentrate on how chemical potential and intrinsic electrical properties of materials can be used to generate smaller, but important, amounts of electricity.

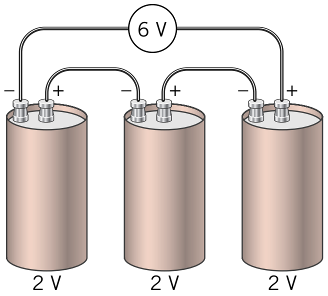


The oldest known electric battery in existence, discovered in 1938 in Baghdad, Iraq, consists of a copper tube surrounding an iron rod. If filled with an acidic liquid such as vinegar, the cell could produce a small electric current. *(Smith College Museum of Ancient Inventions)*

Batteries

One of the most familiar uses of galvanic cells, popularly called *batteries*, is the generation of portable electrical energy.[7] These devices are classified as either **primary cells** (cells not designed to be recharged; they are discarded after their energy is depleted) or **secondary cells** (cells designed for repeated use; they are able to be recharged).

Lead Storage Batteries



If three 2 volt cells are connected in series, their voltages are additive to provide a total of 6 volts. In today's autos, 12 volt batteries containing six cells are the norm.

The common **lead storage battery** used to start an automobile is composed of a number of secondary cells, each having a potential of about 2 V, that are connected in series so that their voltages are additive. Most automobile batteries contain six such cells and give about 12 V, but 6, 24, and 32 V batteries are also available.

A typical lead storage battery is illustrated in Figure 20.10. The anode of each cell is composed of a set of lead plates, the cathode consists of another set of plates that hold a coating of PbO_2, and the electrolyte is sulfuric acid. When the battery is discharging, the electrode reactions are

$$PbO_2(s) + 3H^+(aq) + HSO_4^-(aq) + 2e^- \longrightarrow PbSO_4(s) + 2H_2O \qquad \text{(cathode)}$$

$$Pb(s) + HSO_4^-(aq) \longrightarrow PbSO_4(s) + H^+(aq) + 2e^- \qquad \text{(anode)}$$

The net reaction taking place in each cell is

$$PbO_2(s) + Pb(s) + \underbrace{2H^+(aq) + 2HSO_4^-(aq)}_{2H_2SO_4} \longrightarrow 2PbSO_4(s) + 2H_2O$$

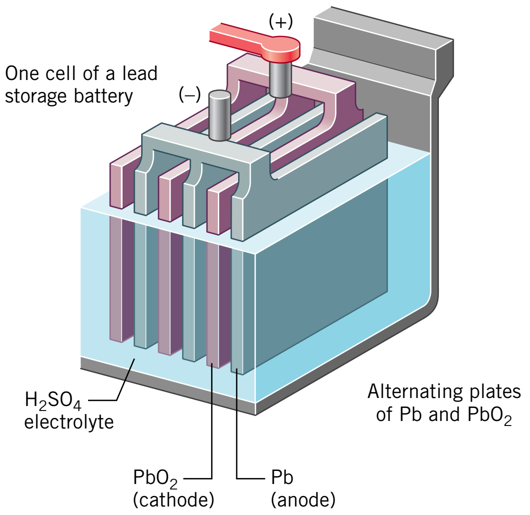
As the cell discharges, the sulfuric acid concentration decreases, which causes the density of the electrolyte to drop. The state of charge of the battery can be monitored with a **hydrometer**, which consists of a rubber bulb that is used to draw the battery fluid into a glass tube containing a float (see Figure 20.11). The depth to which the float sinks is inversely proportional to the density of the liquid—the deeper the float sinks, the lower is the density of the acid and the weaker is the charge on the battery. The narrow neck of the float is usually marked to indicate the state of charge of the battery.

The principal advantage of the lead storage battery is that the cell reactions that occur spontaneously during discharge can be reversed by the application of a voltage from an external source. In other words, the battery can be recharged by electrolysis. The reaction for battery recharge is

$$2PbSO_4(s) + 2H_2O \xrightarrow{\text{electrolysis}} PbO_2(s) + Pb(s) + 2H^+(aq) + 2HSO_4^-(aq)$$

---

[7] Strictly speaking, a cell is a single electrochemical unit consisting of a cathode and an anode. A battery is a collection of cells connected in series.



One cell of a lead storage battery
(+)
(–)
H_2SO_4 electrolyte
Alternating plates of Pb and PbO_2
PbO_2 (cathode)
Pb (anode)

Figure 20.10 | **Lead storage battery.** A 12 volt lead storage battery, such as those used in most automobiles, consists of six cells like the one shown here. Notice that the anode and cathode each consist of several plates connected together. This allows the cell to produce the large currents necessary to start a car.

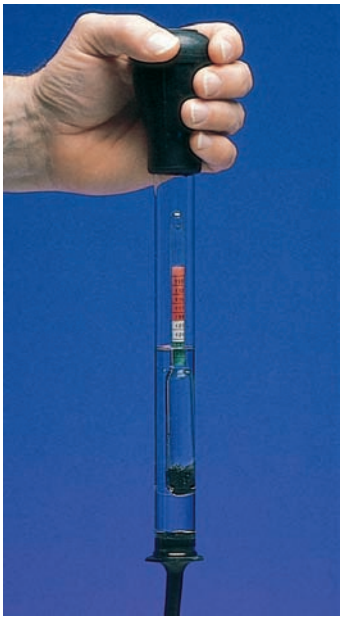


Figure 20.11 | **A battery hydrometer.** Battery acid is drawn into the glass tube. The depth to which the float sinks is inversely proportional to the concentration of the acid and, therefore, to the state of charge of the battery. *(OPC, Inc.)*

Improper recharging of lead-acid batteries can produce potentially explosive H_2 gas. Most modern lead storage batteries use a lead–calcium alloy as the anode. That reduces the need to have the individual cells vented, and the battery can be sealed, thereby preventing spillage of the corrosive electrolyte.

Zinc–Manganese Dioxide Cells

The original, relatively inexpensive 1.5 V dry cell is the **zinc–manganese dioxide cell**, or **Leclanché cell** (named after its inventor George Leclanché). It is a primary cell used to power flashlights, toys, and the like, but it is not really dry (see Figure 20.12). Its outer shell is made of zinc, which serves as the anode. The cathode—the positive terminal of the battery—consists of a carbon (graphite) rod surrounded by a moist paste of graphite powder, manganese dioxide, and ammonium chloride.

■ This is "dry" compared to the lead-acid battery, which has a significant volume of liquid sulfuric acid solution.

The anode reaction is simply the oxidation of zinc.

$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^- \qquad \text{(anode)}$$

The cathode reaction is complex, and a mixture of products is formed. One of the major reactions is

$$2MnO_2(s) + 2NH_4^+(aq) + 2e^- \longrightarrow Mn_2O_3(s) + 2NH_3(aq) + H_2O \qquad \text{(cathode)}$$

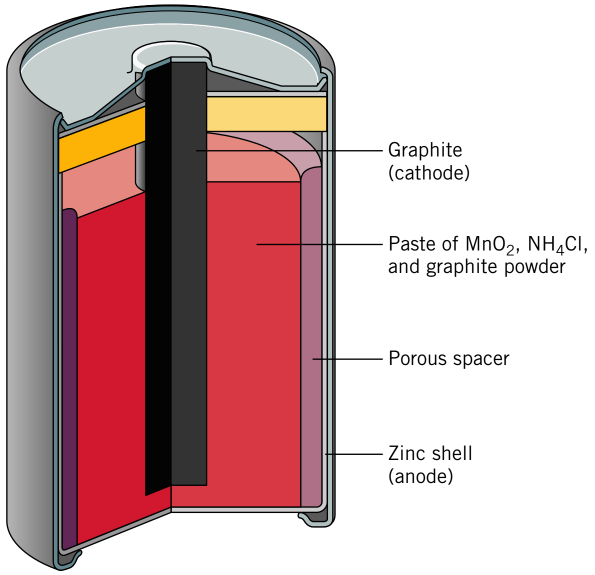

Figure 20.12 | **A cut-away view of a zinc–carbon dry cell (Leclanché cell).**

The ammonia that forms at the cathode reacts with some of the Zn^{2+} produced from the anode to form a complex ion, $Zn(NH_3)_4{}^{2+}$. Because of the complexity of the cathode half-cell reaction, no simple overall cell reaction can be written.

■ The alkaline battery is also a primary cell.

A more popular version of the Leclanché battery uses a basic, or *alkaline*, electrolyte and is called an **alkaline battery** or **alkaline dry cell.** It too uses Zn and MnO_2 as reactants, but under basic conditions (Figure 20.13). The half-cell reactions are

$$\begin{array}{lr} Zn(s) + 2OH^-(aq) \longrightarrow ZnO(s) + H_2O + 2e^- & \text{(anode)} \\ 2MnO_2(s) + H_2O + 2e^- \longrightarrow Mn_2O_3(s) + 2OH^-(aq) & \text{(cathode)} \\ \hline Zn(s) + 2MnO_2(s) \longrightarrow ZnO(s) + Mn_2O_3(s) & \text{(net cell reaction)} \end{array}$$

and the voltage is about 1.54 V. It has a longer shelf life and is able to deliver higher currents for longer periods than the less expensive zinc–carbon cell.

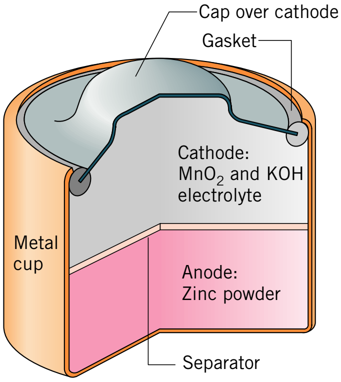

Figure 20.13 | **A simplified diagram of an alkaline dry cell.**

Nickel–Cadmium Rechargeable Batteries

The **nickel–cadmium storage cell**, or **nicad battery**, is a secondary cell that produces a potential of about 1.4 V, which is slightly lower than that of the zinc–carbon cell. The electrode reactions in the cell during discharge are

$$\begin{array}{lr} Cd(s) + 2OH^-(aq) \longrightarrow Cd(OH)_2(s) + 2e^- & \text{(anode)} \\ NiO_2(s) + 2H_2O + 2e^- \longrightarrow Ni(OH)_2(s) + 2OH^-(aq) & \text{(cathode)} \\ \hline Cd(s) + NiO_2(s) + 2H_2O \longrightarrow Ni(OH)_2(s) + Cd(OH)_2(s) & \text{(net cell reaction)} \end{array}$$

The nickel–cadmium battery can be recharged, in which case the anode and cathode reactions above are reversed to remake the reactants. The battery also can be sealed to prevent leakage, which is particularly important in electronic devices.

■ If a battery can supply large amounts of energy and is contained in a small package, it will have a desirably high energy density.

Nickel–cadmium batteries work especially well in applications such as portable power tools, CD players, and even electric cars. They have a high **energy density** (available energy per unit volume), they are able to release the energy quickly, and they can be rapidly recharged.

Nickel–Metal Hydride Batteries

These secondary cells, which are often referred to as Ni–MH batteries, have been used extensively in recent years to power devices such as cell phones, camcorders, and even electric vehicles. They are similar in many ways to the alkaline nickel–cadmium cells discussed above, except for the anode reactant, which is hydrogen. This is possible because certain metal alloys [e.g., $LaNi_5$ (an alloy of lanthanum and nickel) and Mg_2Ni (an alloy of magnesium and nickel)] have the ability to absorb and hold substantial amounts of hydrogen, and the hydrogen can be made to participate in reversible electrochemical reactions. The term *metal hydride* is used to describe the hydrogen-holding alloy.

■ There are compounds of hydrogen with metals such as sodium that actually contain the *hydride ion*, H^-. The metal "hydrides" described here are not of that type.

The cathode in the Ni–MH cell is NiO(OH), a compound of nickel in the +3 oxidation state, and the electrolyte is a solution of KOH. Using the symbol MH to stand for the metal hydride, the reactions in the cell during discharge are:

$$\begin{array}{lr} MH(s) + OH^-(aq) \longrightarrow M(s) + H_2O + e^- & \text{(anode)} \\ NiO(OH)(s) + H_2O + e^- \longrightarrow Ni(OH)_2(s) + OH^-(aq) & \text{(cathode)} \end{array}$$

The overall cell reaction is

$$MH(s) + NiO(OH)(s) \longrightarrow Ni(OH)_2(s) + M(s) \qquad E^\circ_{\text{cell}} = 1.35\ \text{V}$$

When the cell is recharged, these reactions are reversed.

The principal advantage of the Ni–MH cell over the Ni–Cd cell is that it can store about 50% more energy in the same volume. This means, for example, that comparing cells of the same size and weight, a nickel–metal hydride cell can power a laptop computer or a cell phone about 50% longer than a nickel–cadmium cell.

Lithium Batteries

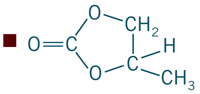
Lithium has the most negative standard reduction potential of any metal (Table 20.1), so it has a lot of appeal as an anode material. Furthermore, lithium is a very lightweight metal, so a cell employing lithium as a reactant would also be lightweight. The major problem with using lithium in a galvanic cell is that the metal reacts vigorously with water to produce hydrogen gas and lithium hydroxide.

$$2\text{Li}(s) + 2\text{H}_2\text{O} \longrightarrow 2\text{LiOH}(aq) + \text{H}_2(g)$$

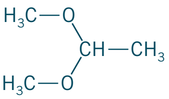
Therefore, to employ lithium in a galvanic cell, scientists had to find a way to avoid aqueous electrolytes. This became possible in the 1970s with the introduction of organic solvents and solvent mixtures that were able to dissolve certain lithium salts and thereby serve as electrolytes.

Today's lithium batteries fall into two categories, primary batteries that can be used once and then discarded when fully discharged, and rechargeable cells.

One of the most common nonrechargeable cells is the **lithium–manganese dioxide battery**, which accounts for about 80% of all primary lithium cells. This cell uses a solid lithium anode and a cathode made of heat-treated MnO_2. The electrolyte is a mixture of propylene carbonate and dimethoxyethane (see the structures in the margin) containing a dissolved lithium salt such as LiClO_4. The cell reactions are as follows (superscripts are the oxidation numbers of the manganese):



propylene carbonate



dimethoxyethane

$$\begin{array}{rcll} \text{Li} & \longrightarrow & \text{Li}^+ + e^- & \text{(anode)} \\ \text{Mn}^{\text{IV}}\text{O}_2 + \text{Li}^+ + e^- & \longrightarrow & \text{Mn}^{\text{III}}\text{O}_2(\text{Li}^+) & \text{(cathode)} \\ \hline \text{Li} + \text{Mn}^{\text{IV}}\text{O}_2 & \longrightarrow & \text{Mn}^{\text{III}}\text{O}_2(\text{Li}^+) & \text{(net cell reaction)} \end{array}$$

This cell produces a voltage of about 3.4 V, which is more than twice that of an alkaline dry cell, and because of the light weight of the lithium, it produces more than twice as much energy for a given weight. These cells are used in applications that require a higher current drain or energy pulses (e.g., a photoflash).

Lithium Ion Cells

Rechargeable lithium batteries found in many cell phones, digital cameras, and laptop computers do not contain metallic lithium. They are called **lithium ion cells** and use lithium ions instead. In fact, the cell's operation doesn't actually involve true oxidation and reduction. Instead, it uses the transport of Li^+ ions through the electrolyte from one electrode to the other accompanied by the transport of electrons through the external circuit to maintain charge balance. Here's how it works.

It was discovered that Li^+ ions are able to slip between layers of atoms in certain crystals such as graphite[8] and LiCoO_2 (a process called **intercalation**). When the cell is constructed, it is in its "uncharged" state, with no Li^+ ions between the layers of carbon atoms in the graphite. When the cell is charged (Figure 20.14*a*), Li^+ ions leave LiCoO_2 and travel through the electrolyte to the graphite (represented below by the formula C_6).

■ Pronounced in-*ter*-ca-*la*-tion. Rhymes with *percolation*.

Initial charging:

$$\text{LiCoO}_2 + \text{C}_6 \longrightarrow \text{Li}_{1-x}\text{CoO}_2 + \text{Li}_x\text{C}_6$$

When the cell spontaneously discharges to provide electrical power (Figure 20.14*b*), Li^+ ions move back through the electrolyte to the cobalt oxide while electrons move through the external circuit from the graphite electrode to the cobalt oxide electrode. If we represent the amount of Li^+ transferring by y, the discharge "reaction" is

Discharge:

$$\text{Li}_{1-x}\text{CoO}_2 + \text{Li}_x\text{C}_6 \longrightarrow \text{Li}_{1-x+y}\text{CoO}_2 + \text{Li}_{x-y}\text{C}_6$$

■ In these equations, the subscript x indicates that *some*, *but not all*, of the Li^+ ions migrate to the graphite in the charging process. Similarly, the subscript y represents the fraction of Li^+ ions that migrate back as electron flow is generated.

Thus, the charging and discharging cycles simply sweep Li^+ ions back and forth between the two electrodes, with the electrons flowing through the external circuit to keep the charge in balance.

---

[8] Graphite is one of the forms of elemental carbon and consists of layers of joined benzene-like rings.

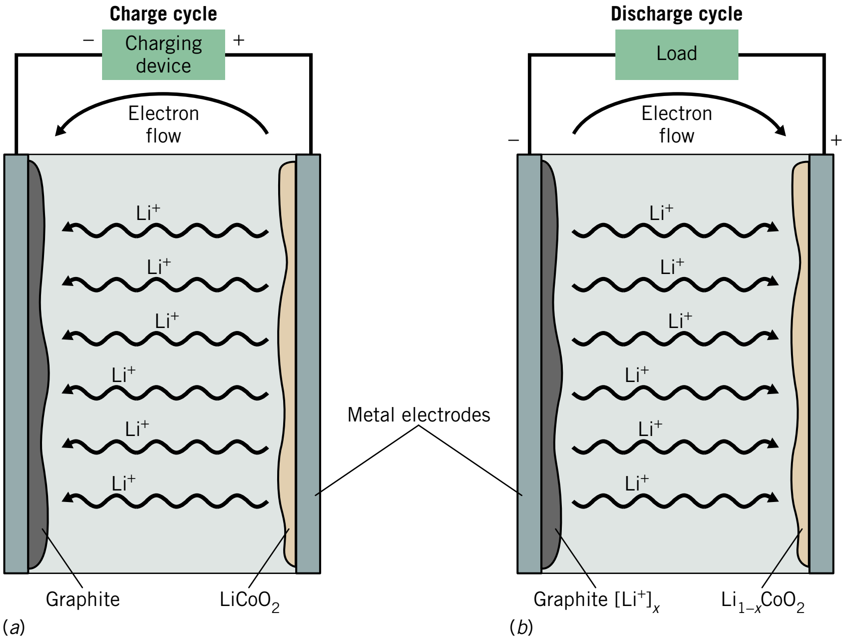


Figure 20.14 | **Lithium ion cell.** (*a*) During the charging cycle, an external voltage forces electrons through the external circuit and causes lithium ions to travel from the $LiCoO_2$ electrode to the graphite electrode. (*b*) During discharge, the lithium ions spontaneously migrate back to the $LiCoO_2$ electrode, and electrons flow through the external circuit to balance the charge.

Fuel Cells

The galvanic cells we've discussed until now can only produce power for a limited time because the electrode reactants are eventually depleted. Fuel cells are different; they are electrochemical cells in which the electrode reactants are supplied continuously and are able to operate without theoretical limit as long as the supply of reactants is maintained. This makes fuel cells an attractive source of power where long-term generation of electrical energy is required.

Figure 20.15 illustrates an early design of a hydrogen–oxygen **fuel cell**. The electrolyte, a hot (~200 °C) concentrated solution of potassium hydroxide in the center compartment, is in contact with two porous electrodes that contain a catalyst (usually platinum) to facilitate the electrode reactions. Gaseous hydrogen and oxygen under pressure are circulated so as to come in contact with the electrodes. At the cathode, oxygen is reduced.

$$O_2(g) + 2H_2O + 4e^- \longrightarrow 4OH^-(aq) \qquad \text{(cathode)}$$

At the anode, hydrogen is oxidized to water.

$$H_2(g) + 2OH^-(aq) \longrightarrow 2H_2O + 2e^- \qquad \text{(anode)}$$

Part of the water formed at the anode leaves as steam mixed with the circulating hydrogen gas. The net cell reaction, after making electron loss equal to electron gain, is

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O \qquad \text{(net cell reaction)}$$

Hydrogen–oxygen fuel cells are an attractive alternative to gasoline-powered engines in part because they are essentially pollution-free—the only product of the reaction is harmless water. Fuel cells are also quite thermodynamically efficient, converting as much as 75% of the available energy to useful work, compared to approximately 25 to 30% for gasoline and diesel engines. Among the major obstacles are the energy costs of generating the hydrogen fuel and problems in providing storage and distribution of the highly flammable H_2.

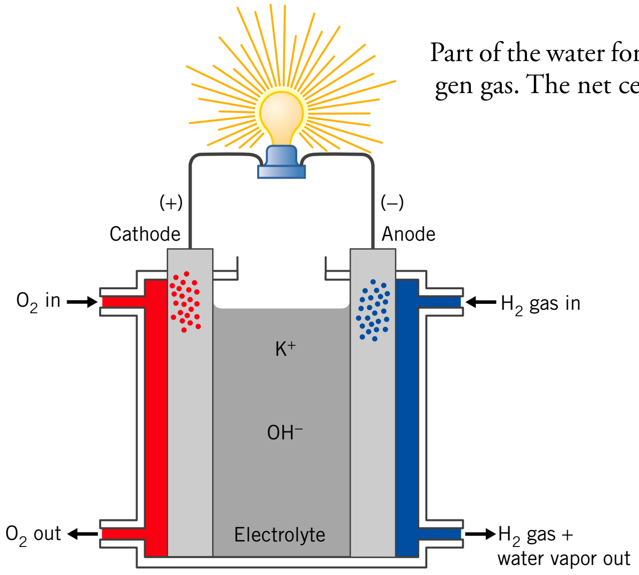

Figure 20.15 | **A hydrogen–oxygen fuel cell.**

Photovoltaic Cells

There exists a wide variety of devices where the electrical properties of materials, combined with the energy of photons, can be used to generate a flow of electrons. These devices are called *photovoltaics*. We have already laid basis of how these devices work in Chapters 8 and 10 when we discussed the photoelectric effect and solar cells.

A photovoltaic device must have a means to (a) separate an electron from a substance and (b) only allow that electron to return to its original site after moving through an external electrical circuit. In the process of traveling through the electrical circuit, the energy of that electron can be used to perform useful work.

Although modern photovoltaic devices are quite sophisticated, we can investigate a simple model to understand the basics. We start with ultrapure silicon (or germanium). These are semiconductors and are not useful until a controlled amount of impurity, in the form of phosphorous or boron, is added (this process is called doping). Referring to Chapter 10, we know that silicon should form a tetrahedral network crystal similar to diamond. If boron is added, it will replace a silicon atom in the crystal with one important difference: it can only form three bonds with the four neighboring silicon atoms. The absent bond is called a **hole** or a **positive charge carrier**. If phosphorus is added, it has five valence electrons. Four of these bond with four neighboring silicon atoms, leaving one extra electron that can move through the crystal as a **negative charge carrier**. For simplicity we call the boron doped semiconductor a *p-type* material and the phosphorus doped silicon an *n-type* semiconductor.

When n-type and p-type semiconductor materials are joined together we form a semiconductor junction that has unique properties. First, electrons from the n-type material move to the p-type material and combine with available holes. The result is a layer depleted of charge carriers, both electrons and holes. This depletion layer inhibits further flow of charge. If the negative end of a battery is connected to the n-type material, the depletion layer shrinks and electrons can flow from the n-type to the p-type material. If the battery is reversed, the depletion layer expands and electrons cannot flow in the reverse direction. This is a classic diode where electrons can flow only one way.

Now let's consider what happens if we hit these semiconductors with photons that have enough energy to excite some electrons, creating electron-hole pairs. These pairs could recombine with each other, or with other holes and electrons within the diode. That would not provide a useful flow of electrons. To be useful, another, easier, path for the electrons must be provided. We provide this pathway by adding wires (electrodes) to each side of the diode in order to connect it to an external circuit. This external circuit provides an easier route for the electrons to flow from the n-type back to the p-type material. Of course, we can add a light bulb, motor, meter, computer, or any other electric device to take advantage of this flow of electrons.

To expand our simple photocell to a useful device, we need to add a few extras as illustrated in Figure 20.16. First, we add a glass covering to protect our device from the

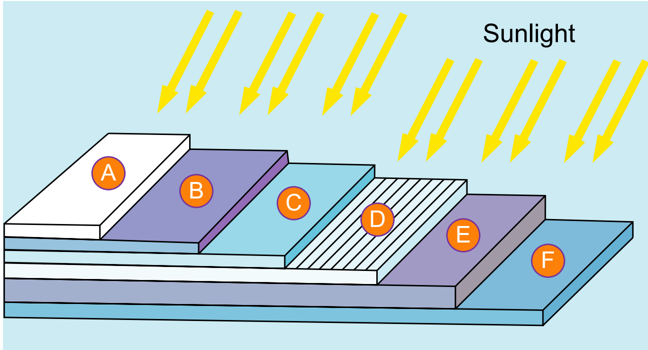

Figure 20.16 | **Diagram of the internal parts of a photovoltaic cell.** (a) Glass protective covering, (b) antireflective coating, (c) electrode mesh, (d) n-type semiconductor material, (e) p-type semiconductor material, (f) electrode. The thickness of this cell is approximately 0.3 mm, and the n-type semiconductor is approximately 0.002 mm thick.

Figure 20.17 | **Acres of photovoltaic cells can produce large amounts of energy.** *(© Fotosearch/Purestock/SuperStock)*

elements. Next, to capture all the sunlight possible, an anti-reflective coating is added, and then we have a metallic mesh cathode added to the n-type material so that light can get through. Next is the junction with the p-type semiconductor and, finally, the metal that forms the anode. Since each photovoltaic cell produces about 0.5 volt, 24 cells may be connected in series to produce a 12 volt device. Different groupings of the photo cells may be designed to improve either the voltage or current rating of the device. Figure 20.17 illustrates part of a large array of photovoltaics that could be used to power a small group of homes or stores.

20.7 | Electrolytic Cells

In our preceding discussions, we've examined how spontaneous redox reactions can be used to generate electrical energy. We now turn our attention to the opposite process, the use of electrical energy to force nonspontaneous redox reactions to occur.

When electricity is passed through a molten (melted) ionic compound or through a solution of an electrolyte, a chemical reaction occurs that we call **electrolysis.** A typical electrolysis apparatus, called an **electrolysis cell** or **electrolytic cell**, is shown in Figure 20.18. This particular cell contains molten sodium chloride. (A substance undergoing electrolysis must be molten or in solution so its ions can move freely and conduction can occur.) *Inert electrodes*—electrodes that won't react with the molten NaCl or the electrolysis products—are dipped into the cell and then connected to a source of direct current (DC) electricity.

■ To perform electrolysis, we must use direct current in which electrons move in only one direction, not in the oscillating, back and forth pattern of alternating current.

The DC source serves as an "electron pump," pulling electrons away from one electrode and pushing them through the external wiring onto the other electrode. The electrode from which electrons are removed becomes positively charged, while the other electrode becomes negatively charged. When electricity starts to flow, chemical changes begin to happen. At the positive electrode, oxidation occurs as electrons are pulled away from negatively charged chloride ions. Because of the nature of the chemical change, therefore, *the positive electrode becomes the anode*. The DC source pumps the electrons through the external electrical circuit to the negative electrode. Here reduction takes place as the electrons are forced onto positively charged sodium ions, so *the negative electrode is the cathode*.

The chemical changes that occur at the electrodes can be described by chemical equations.

$$\mathrm{Na}^+(l) + e^- \longrightarrow \mathrm{Na}(l) \qquad \text{(cathode)}$$

$$2\mathrm{Cl}^-(l) \longrightarrow \mathrm{Cl}_2(g) + 2e^- \qquad \text{(anode)}$$

As in a galvanic cell, the overall reaction that takes place in the electrolysis cell is called the *cell reaction*. To obtain it, we add the individual electrode half-reactions together,

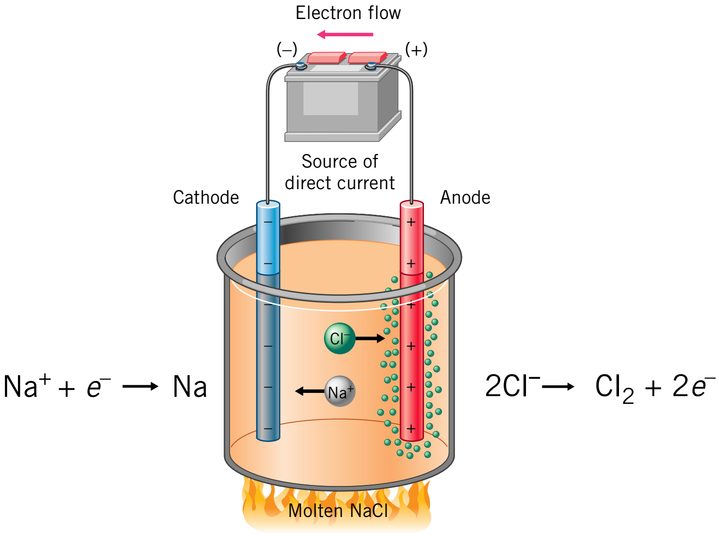

Figure 20.18 | **Electrolysis of molten sodium chloride.** In this electrolysis cell, the passage of an electric current decomposes molten sodium chloride into metallic sodium and gaseous chlorine. Unless the products are kept apart, they react on contact to re-form NaCl.

making sure that the number of electrons gained in one half-reaction equals the number lost in the other.

$$2Na^+(l) + 2e^- \longrightarrow 2Na(l) \qquad \text{(cathode)}$$

$$2Cl^-(l) \longrightarrow Cl_2(g) + 2e^- \qquad \text{(anode)}$$

$$2Na^+(l) + 2Cl^-(l) + \cancel{2e^-} \longrightarrow 2Na(l) + Cl_2(g) + \cancel{2e^-} \qquad \text{(cell reaction)}$$

As you know, table salt is quite stable. It doesn't normally decompose because the reverse reaction, the reaction of sodium and chlorine to form sodium chloride, is highly spontaneous. Therefore, we often write the word *electrolysis* above the arrow in the equation to show that electricity is the driving force for this otherwise nonspontaneous reaction.

$$2Na^+(l) + 2Cl^-(l) \xrightarrow{\text{electrolysis}} 2Na(l) + Cl_2(g)$$

Comparing Electrolytic and Galvanic Cells

In a galvanic cell, the spontaneous cell reaction deposits electrons on the anode and removes them from the cathode. As a result, the anode carries a slight negative charge and the cathode a slight positive charge. In most galvanic cells the reactants must be placed in separate compartments. In an *electrolysis cell*, the situation is reversed. Often the two electrodes are immersed in the same liquid. Also, the oxidation at the anode must be forced to occur, which requires that the anode be positive so it can remove electrons from the reactant at that electrode. On the other hand, the cathode must be made negative so it can force the reactant at the electrode to accept electrons.

Electrolytic Cell	**Galvanic Cell**
Cathode is negative (reduction).	Cathode is positive (reduction).
Anode is positive (oxidation).	Anode is negative (oxidation).
Anode and cathode are often in the same compartment.	Anode and cathode are usually in separate compartments.

Even though the charges on the cathode and anode differ between electrolytic cells and galvanic cells, the ions in solution always move in the same direction. In both types of cells, positive ions (cations) move toward the cathode. They are attracted there by the negative charge on the cathode in an electrolysis cell; they diffuse toward the cathode in a galvanic cell to balance the charge of negative ions left behind when ions are reduced.

■ By agreement among scientists, the names anode and cathode are assigned according to the nature of the reaction taking place at the electrode. If the reaction is oxidation, the electrode is called the anode; if it's reduction, the electrode is called the cathode.

Similarly, negative ions (anions) move toward the anode. They are attracted to the positive anode in an electrolysis cell, and they diffuse toward the anode in our galvanic cell to balance the charge of the positive ions entering the solution.

Electrolysis at the Molecular Level

The electrical conductivity of a molten salt or a solution of an electrolyte is possible only because of the reactions that take place at the surface of the electrodes. For example, when charged electrodes are dipped into molten NaCl they become surrounded by a layer of ions of the opposite charge. Let's look closely at what happens at one of the electrodes—say, the anode (Figure 20.19). Here the positive charge of the electrode attracts negative Cl^- ions, which form a coating on the electrode's surface. The charge on the anode pulls electrons from the ions, causing them to be oxidized and changing them into neutral Cl atoms that join to become Cl_2 molecules. Because the molecules are neutral, they are not held by the electrode and so move away from the electrode's surface. Their places are quickly taken by negative ions from the surrounding liquid, which tends to leave the surrounding liquid positively charged. Other negative ions from farther away move toward the anode to keep the liquid there electrically neutral. In this way, negative ions gradually migrate toward the anode. By a similar process, positive ions diffuse through the liquid toward the negatively charged cathode, where they become reduced.

■ Cations (positive ions) move toward the cathode and anions (negative ions) migrate toward the anode. This happens in both electrolytic and galvanic cells.

Electrolysis of Water in Aqueous Systems

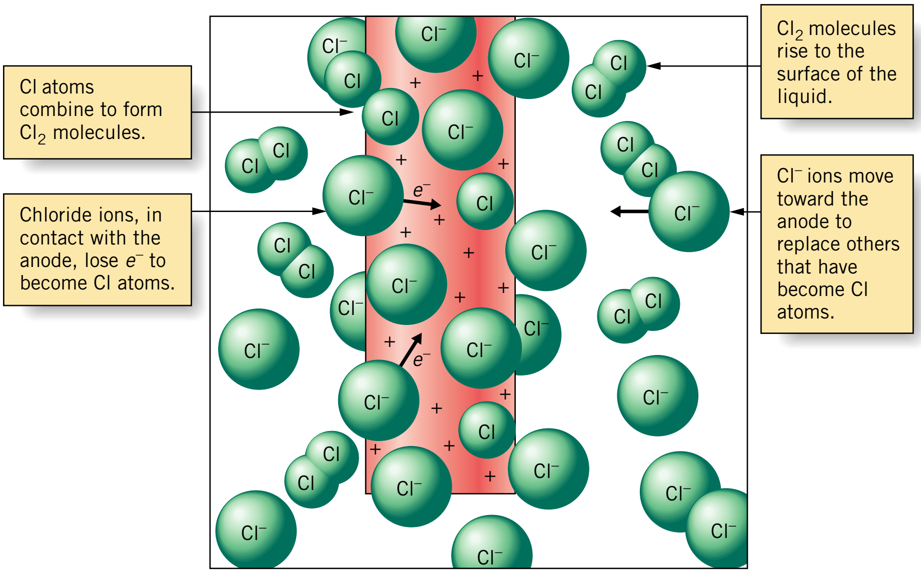
When electrolysis is carried out in an aqueous solution, the electrode reactions are more difficult to predict because at the electrodes there are competing reactions. Not only do we have to consider the possible oxidation and reduction of the solute, but also the oxidation and reduction of water. For example, consider what happens when electrolysis is performed on a solution of potassium sulfate (Figure 20.20). The products are hydrogen and oxygen. At the cathode, water is reduced, not K^+.

$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad \text{(cathode)}$$

At the anode, water is oxidized, not the sulfate ion.

$$2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^- \qquad \text{(anode)}$$

Color changes of an acid–base indicator dissolved in the solution confirm that the solution becomes basic around the cathode, where OH^- is formed, and acidic around the



Cl atoms combine to form Cl_2 molecules.

Chloride ions, in contact with the anode, lose e^- to become Cl atoms.

Cl_2 molecules rise to the surface of the liquid.

Cl^- ions move toward the anode to replace others that have become Cl atoms.

Figure 20.19 | **A microscopic view of changes at the anode in the electrolysis of molten NaCl.** The positive charge of the electrode attracts a coating of Cl^- ions. At the surface of the electrode, electrons are pulled from the ions, yielding neutral Cl atoms, which combine to form Cl_2 molecules that move away from the electrode and eventually rise to the surface as a gas.

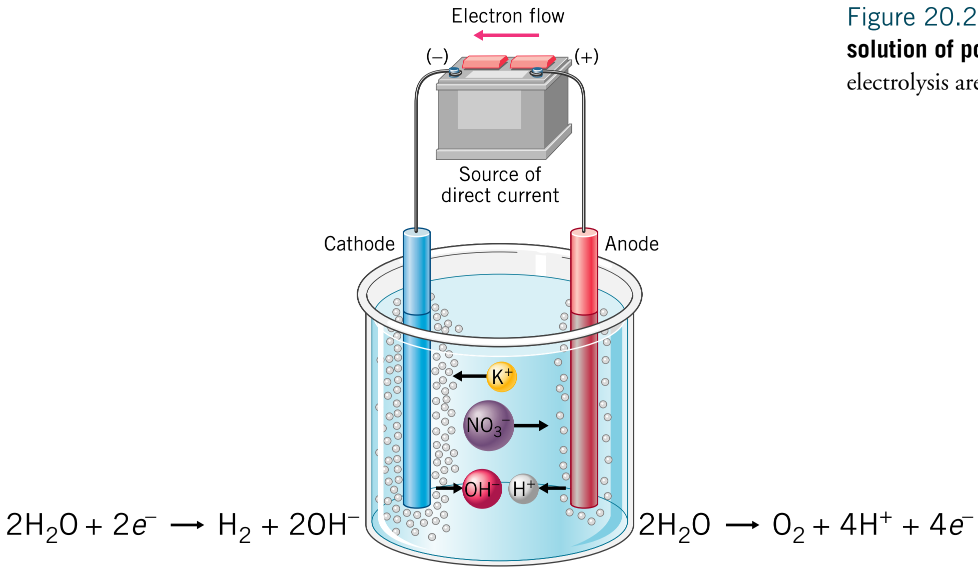


Figure 20.20 | **Electrolysis of an aqueous solution of potassium sulfate.** The products of the electrolysis are the gases hydrogen and oxygen.

Electron flow
(–)
(+)
Source of direct current
Cathode
Anode
K^+
NO_3^-
OH^-
H^+
$2H_2O + 2e^- \longrightarrow H_2 + 2OH^-$
$2H_2O \longrightarrow O_2 + 4H^+ + 4e^-$

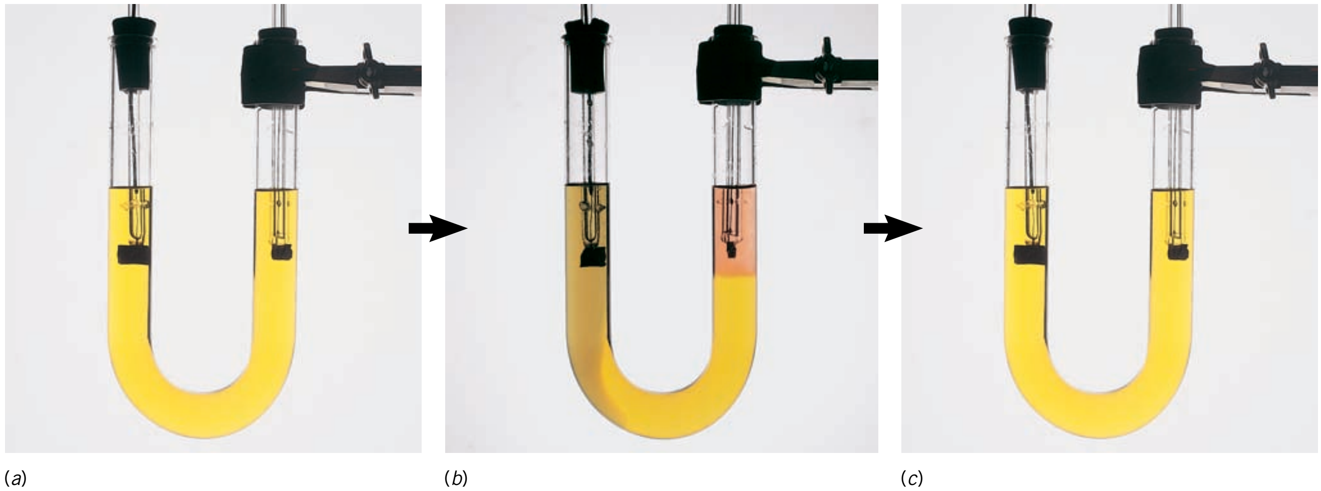
anode, where H^+ is formed (see Figure 20.21). In addition, the gases H_2 and O_2 can be separately collected.

We can understand why these redox reactions happen if we examine the standard reduction potential data from Table 20.1. For example, at the cathode we have the following competing reactions.

$$K^+(aq) + e^- \longrightarrow K(s) \qquad E^\circ_{K^+} = -2.92\text{ V}$$

$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad E^\circ_{H_2O} = -0.83\text{ V}$$

Water has a much less negative (and therefore more positive) standard reduction potential than K^+, which means H_2O is much easier to reduce than K^+. As a result, when the electrolysis is performed the more easily reduced substance is reduced and we observe H_2 being formed at the cathode.



(*a*) (*b*) (*c*)

Figure 20.21 | **Electrolysis of an aqueous solution of potassium sulfate in the presence of acid–base indicators.** (*a*) The initial yellow color indicates that the solution is neutral (neither acidic nor basic). (*b*) As the electrolysis proceeds, H^+ is produced at the anode (along with O_2) and causes the solution there to become pink. At the cathode, H_2 is evolved and OH^- ions are formed, which turns the solution around that electrode a bluish violet. (*c*) After the electrolysis is stopped and the solution is stirred, the color becomes yellow again as the H^+ and OH^- ions formed by the electrolysis neutralize each other. *(Michael Watson)*

At the anode we have the following possible oxidation half-reactions.

$$\begin{aligned} 2SO_4{}^{2-}(aq) &\longrightarrow S_2O_8{}^{2-}(aq) + 2e^- \\ 2H_2O &\longrightarrow 4H^+(aq) + O_2(g) + 2e^- \end{aligned}$$

In Table 20.1, we find them written in the opposite direction:

$$\begin{aligned} S_2O_8{}^{2-}(aq) + 2e^- &\longrightarrow 2SO_4{}^{2-}(aq) & E^\circ_{S_2O_8{}^{2-}} &= +2.01\text{ V} \\ O_2(g) + 4H^+(aq) + 4e^- &\longrightarrow 2H_2O & E^\circ_{O_2} &= +1.23\text{ V} \end{aligned}$$

The E° values tell us that $S_2O_8{}^{2-}$ is much more easily reduced than O_2. But if $S_2O_8{}^{2-}$ is the *more easily reduced*, then the product, $SO_4{}^{2-}$, must be *the less easily oxidized*. Stated another way, *the half-reaction with the smaller standard reduction potential is more easily reversed as an oxidation*. As a result, when electrolysis is performed, water is oxidized instead of $SO_4{}^{2-}$ and we observe O_2 being formed at the anode.

The overall cell reaction for the electrolysis of the K_2SO_4 solution can be obtained as before. Because the number of electrons lost has to equal the number gained, the cathode reaction must occur twice each time the anode reaction occurs once.

$$\begin{aligned} 2 \times [2H_2O(l) + 2e^- &\longrightarrow H_2(g) + 2OH^-(aq)] & &\text{(cathode)} \\ 2H_2O(l) &\longrightarrow O_2(g) + 4H^+(aq) + 4e^- & &\text{(anode)} \end{aligned}$$

After adding, we combine the coefficients for water and cancel the electrons from both sides to obtain the cell reaction.

$$6H_2O(l) \longrightarrow 2H_2(g) + O_2(g) + 4H^+(aq) + 4OH^-(aq)$$

Notice that hydrogen ions and hydroxide ions are produced in equal numbers. In Figure 20.21, we see that when the solution is stirred, they combine to form water.

$$6H_2O(l) \longrightarrow 2H_2(g) + O_2(g) + \underbrace{4H^+(aq) + 4OH^-(aq)}_{4H_2O}$$

The net change, then, is

$$2H_2O \xrightarrow{\text{electrolysis}} 2H_2(g) + O_2(g)$$

Function of Spectator Ions in Electrolysis

Although neither K^+ nor $SO_4{}^{2-}$ is changed by the reaction, K_2SO_4 or some other electrolyte is needed for the electrolysis to proceed. Its function is to maintain electrical neutrality at the electrodes. At the anode, H^+ ions are formed and their charge can be balanced by mixing with $SO_4{}^{2-}$ ions of the solute. Similarly, at the cathode the K^+ ions are able to mix with OH^- ions as they are formed, thereby balancing the charge and keeping the solution electrically neutral. In this way, at any moment, each small region of the solution is able to contain the same number of positive and negative charges and thereby remain neutral.

Standard Reduction Potentials and Electrolysis Products

Suppose we wish to know what products are expected in the electrolysis of an aqueous solution of copper(II) bromide, $CuBr_2$. Let's examine the possible electrode half-reactions and their respective standard reduction potentials.

At the cathode, possible reactions are the reduction of copper ion and the reduction of water. From Table 20.1,

$$\begin{aligned} Cu^{2+}(aq) + 2e^- &\longrightarrow Cu(s) & E^\circ_{Cu^{2+}} &= +0.34\text{ V} \\ 2H_2O(l) + 2e^- &\longrightarrow H_2(g) + 2OH^-(aq) & E^\circ_{H_2O} &= -0.83\text{ V} \end{aligned}$$

The much more positive reduction standard potential for Cu^{2+} tells us to anticipate that Cu^{2+} will be reduced at the cathode.

At the anode, possible reactions are the oxidation of Br^- and the oxidation of water. The half-reactions are

$$\begin{aligned} 2Br^-(aq) &\longrightarrow Br_2(aq) + 2e^- \\ 2H_2O(l) &\longrightarrow O_2(g) + 4H^+(aq) + 4e^- \end{aligned}$$

In Table 20.1, they are written as reductions with the following $E°$ values.

$$\begin{aligned} Br_2(aq) + 2e^- &\longrightarrow 2Br^-(aq) & E°_{Br_2} &= +1.07\text{ V} \\ O_2(g) + 4H^+(aq) + 4e^- &\longrightarrow 2H_2O(l) & E°_{O_2} &= +1.23\text{ V} \end{aligned}$$

The data tell us that O_2 is more easily reduced than Br_2, which means that Br^- is more easily oxidized than H_2O. Therefore, we expect that Br^- will be oxidized at the anode.

In fact, our predictions are confirmed when we perform the electrolysis. The cathode, anode, and net cell reactions are

$$\begin{aligned} Cu^{2+}(aq) + 2e^- &\longrightarrow Cu(s) & &\text{(cathode)} \\ 2Br^-(aq) &\longrightarrow Br_2(aq) + 2e^- & &\text{(anode)} \\ \hline Cu^{2+}(aq) + 2Br^-(aq) &\xrightarrow{\text{electrolysis}} Cu(s) + Br_2(aq) & &\text{(net reaction)} \end{aligned}$$

Example 20.12
Predicting the Products in an Electrolysis Reaction

Electrolysis is planned for an aqueous solution that contains a mixture of 0.50 *M* $ZnSO_4$ and 0.50 *M* $NiSO_4$. On the basis of standard reduction potentials, what products are expected to be observed at the electrodes? What is the expected net cell reaction?

■ **Analysis:** We need to consider the competing reactions at the cathode and the anode. At the cathode, the half-reaction with the *most positive* standard reduction potential will be the one most expected to occur. At the anode, the half-reaction with the *least positive* standard reduction potential is the one that will most readily occur in the reverse, or oxidation, direction.

■ **Assembling the Tools:** Our main tool will be a table of standard reduction potentials. We can use Table 20.1, the expanded table in Appendix Table C.9, or even more extensive tables in reference works.

■ **Solution:** At the cathode, the competing reduction reactions involve the two cations and water. The reactions and their standard reduction potentials are

$$\begin{aligned} Ni^{2+}(aq) + 2e^- &\rightleftharpoons Ni(s) & E° &= -0.25\text{ V} \\ Zn^{2+}(aq) + 2e^- &\rightleftharpoons Zn(s) & E° &= -0.76\text{ V} \\ 2H_2O + 2e^- &\rightleftharpoons H_2(g) + 2OH^-(aq) & E° &= -0.83\text{ V} \end{aligned}$$

The least negative standard reduction potential is that of Ni^{2+}, so we expect this ion to be reduced at the cathode, resulting in solid nickel deposited onto the cathode.

At the anode, the competing oxidation reactions are for water and SO_4^{2-} ion. In Table 20.1, substances oxidized are found on the right side of the half-reactions. The two half-reactions having these as products are

$$\begin{aligned} S_2O_8^{2-}(aq) + 2e^- &\rightleftharpoons 2SO_4^{2-}(aq) & E° &= +2.01\text{ V} \\ O_2(g) + 4H^+(aq) + 4e^- &\rightleftharpoons 2H_2O & E° &= +1.23\text{ V} \end{aligned}$$

The half-reaction with the least positive $E°$ (the second one here) is most easily reversed as an oxidation, so we expect the oxidation half-reaction to be

$$2\mathrm{H_2O} \rightleftharpoons \mathrm{O_2}(g) + 4\mathrm{H^+}(aq) + 4e^-$$

At the anode, we expect O_2 to be formed.

The predicted net cell reaction is obtained by combining the two expected electrode half-reactions, making the electron loss equal to the electron gain.

$$\begin{array}{rlr} 2\mathrm{H_2O} \longrightarrow \mathrm{O_2}(g) + 4\mathrm{H^+}(aq) + 4e^- & & \text{(anode)} \\ 2 \times [\mathrm{Ni^{2+}}(aq) + 2e^- \longrightarrow \mathrm{Ni}(s)] & & \text{(cathode)} \\ \hline 2\mathrm{H_2O} + 2\mathrm{Ni^{2+}}(aq) \longrightarrow \mathrm{O_2}(g) + 4\mathrm{H^+}(aq) + 2\mathrm{Ni}(s) & & \text{(net cell reaction)} \end{array}$$

■ **Are the Answers Reasonable?** We can check the locations of the half-reactions in Table 20.1 to confirm our conclusions. For the reduction step, the higher up in the table a half-reaction is, the greater its tendency to occur as reduction. Among the competing half-reactions at the cathode, the one for Ni^{2+} is highest, so we expect that Ni^{2+} is the easiest to reduce and Ni(*s*) should be formed at the cathode.

For the oxidation step, the lower down in the table a half-reaction is, the easier it is to reverse and cause to occur as oxidation. On this basis, the oxidation of water is easier than the oxidation of SO_4^{2-}, so we expect H_2O to be oxidized and O_2 to be formed at the anode.

Of course, we could also test our prediction by carrying out the electrolysis experimentally.

Practice Exercises

20.23 | In the electrolysis of an aqueous solution containing Fe^{2+} and I^-, what product do we expect at the anode? (*Hint*: Write the three oxidation half-reactions possible at the anode for Fe^{2+}, I^-, and H_2O.)

20.24 | In the electrolysis of an aqueous solution containing both Cd^{2+} and Sn^{2+}, what product do we expect at the cathode?

Sometimes Predictions Fail

Although we can use standard reduction potentials to predict electrolysis reactions most of the time, there are occasions when standard reduction potentials do not successfully predict electrolysis products. Sometimes concentrations, far from standard conditions, will change the sign of the cell potential. The formation of complex ions can also interfere and produce unexpected results. And sometimes the electrodes themselves are the culprits. For example, in the electrolysis of aqueous NaCl using inert platinum electrodes, we find experimentally that Cl_2 is formed at the anode. Is this what we would have expected? Let's examine the standard reduction potentials of O_2 and Cl_2 to find out.

$$\begin{array}{ll} \mathrm{Cl_2}(g) + 2e^- \rightleftharpoons 2\mathrm{Cl^-}(aq) & E° = +1.36\ \mathrm{V} \\ \mathrm{O_2}(g) + 4\mathrm{H^+}(aq) + 4e^- \rightleftharpoons 2\mathrm{H_2O} & E° = +1.23\ \mathrm{V} \end{array}$$

Because of its less-positive standard reduction potential, we would expect the oxygen half-reaction to be the easier to reverse (with water being oxidized to O_2). Thus, standard reduction potentials predict that O_2 should be formed, but experiment shows that Cl_2 is produced. The nature of the electrode surface and how it interacts with oxygen is part of the answer. Further explanation for why this happens is beyond the scope of this text, but the unexpected result does teach us that we must be cautious in predicting products in electrolysis reactions solely on the basis of standard reduction potentials.

20.8 | Electrolysis Stoichiometry

In about 1833, Michael Faraday discovered that the amount of chemical change that occurs during electrolysis is directly proportional to the amount of electrical charge that is passed through an electrolysis cell. For example, the reduction of copper ion at a cathode is given by the equation

$$\text{Cu}^{2+}(aq) + 2e^- \longrightarrow \text{Cu}(s)$$

The equation tells us that to deposit one mole of metallic copper requires two moles of electrons. Thus, the half-reaction for an oxidation or reduction relates the amount of chemical substance consumed or produced to the amount of electrons that the electric current must supply. To use this information, however, we must be able to relate it to electrical measurements that can be made in the laboratory.

The SI unit of electric current is the **ampere (A)** and the SI unit of charge is the *coulomb* (C). A coulomb is the amount of charge that passes by a given point in a wire when an electric current of one ampere flows for one second. This means that coulombs are the product of amperes of current multiplied by seconds. Thus

$$1 \text{ coulomb} = 1 \text{ ampere} \times 1 \text{ second}$$

$$1\ \text{C} = 1\ \text{A s} \tag{20.9}$$

For example, if a current of 4 A flows through a wire for 10 s, 40 C pass by a given point in the wire.

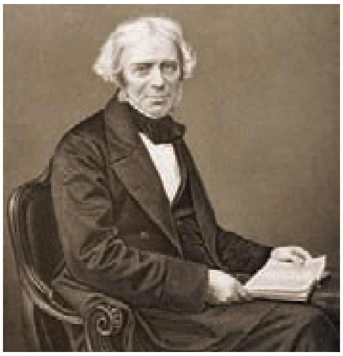
$$\begin{aligned}(4\ \text{A}) \times (10\ \text{s}) &= 40\ \text{A s}\\ &= 40\ \text{C}\end{aligned}$$

As we noted previously, it has been determined that 1 mol of electron carries a charge of 9.65×10^4 C, which, in honor of Michael Faraday, is often called the Faraday constant, $\mathscr{F}$.

$$1 \text{ mol } e^- \Leftrightarrow 9.65 \times 10^4 \text{ C} \quad \left(\begin{array}{c}\text{to three}\\ \text{significant figures}\end{array}\right)$$

$$1\ \mathscr{F} = 9.65 \times 10^4 \text{ C/mol } e^-$$

Now we have a way to relate laboratory measurements to the amount of chemical change that occurs during an electrolysis. Measuring the current in amperes and the time in seconds allows us to calculate the charge sent through the system in coulombs. From this we can get the amount of electrons (in moles), which we can then use to calculate the amount of chemical change produced. The following examples demonstrate the principles involved for electrolysis, but similar calculations also apply to reactions in galvanic cells. Figure 20.22 illustrates how this fits in with our previous stoichiometric calculations. We used similar pathways in Figures 4.6 and 5.27.



Michael Faraday (1791–1867), a British scientist and both a chemist and a physicist, made key discoveries leading to electric motors, generators, and transformers. *(© Classic Image/Alamy)*

Example 20.13

Calculations Related to Electrolysis

How many grams of copper are deposited on the cathode of an electrolytic cell if an electric current of 2.00 A is run through a solution of $CuSO_4$ for a period of 20.0 min?

■ **Analysis:** The wording of this question suggests that our solution will be related to a stoichiometry type of calculation in which we will convert the time and electric current to grams of copper.

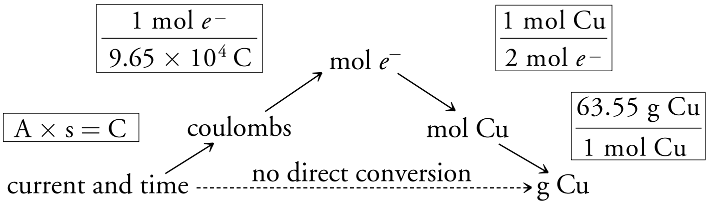
■ **Assembling the Tools:** Figure 20.22 helps us assemble the needed tools. Equation 20.9 is our tool for determining the coulombs of electrons used. Faraday's constant is used as a conversion factor to determine the moles of electrons. Next, the balanced half-reaction serves as our tool for relating moles of electrons to moles of Cu. The ion being reduced is Cu^{2+}, so the half-reaction is

$$Cu^{2+} + 2e^- \longrightarrow Cu$$

Therefore,

$$1 \text{ mol Cu} \Leftrightarrow 2 \text{ mol } e^-$$

Finally, we convert the moles of Cu to mass of Cu using the relationships from Chapter 4. Here's a diagram of the path to the solution.



Since the calculation will be done stepwise we will keep an extra significant figure, that will be rounded at the end.

■ **Solution:** First we convert minutes to seconds

■ $20.0 \text{ min} \times \frac{60 \text{ s}}{1 \text{ min}} = 1.20 \times 10^3 \text{ s}$

$$20.0 \text{ min} = 1.20 \times 10^3 \text{ s}$$

Then we multiply the current by the time to obtain the number of coulombs (1 A s = 1 C).

$$\begin{aligned}(1.20 \times 10^3 \text{ s}) \times (2.00 \text{ A}) &= 2.40 \times 10^3 \text{ A s}\\ &= 2.40 \times 10^3 \text{ C}\end{aligned}$$

Because 1 mol $e^- \Leftrightarrow 9.65 \times 10^4$ C,

$$2.40 \times 10^3 \cancel{\text{C}} \times \frac{1 \text{ mol } e^-}{9.65 \times 10^4 \cancel{\text{C}}} = 0.02487 \text{ mol } e^-$$

Next, we use the relationship between mol e^- and mol Cu from the balanced half-reaction along with the atomic mass of copper.

$$0.02487 \cancel{\text{mol } e^-} \times \left(\frac{1 \cancel{\text{mol Cu}}}{2 \cancel{\text{mol } e^-}}\right) \times \left(\frac{63.55 \text{ g Cu}}{1 \cancel{\text{mol Cu}}}\right) = 0.7903 \text{ g Cu}$$

With proper rounding the electrolysis will deposit 0.790 g of copper on the cathode.

We could have combined all these steps in a single calculation by stringing together the various conversion factors and using the factor-label method to cancel units. In the equation below we are writing 9.65×10^4 C as the equivalent 9.65×10^4 A s.

$$2.00 \cancel{\text{A}} \times 20.0 \cancel{\text{min}} \times \frac{60 \cancel{\text{s}}}{1 \cancel{\text{min}}} \times \frac{1 \cancel{\text{mol } e^-}}{9.65 \times 10^4 \cancel{\text{A}} \cancel{\text{s}}} \times \frac{1 \cancel{\text{mol Cu}}}{2 \cancel{\text{mol } e^-}} \times \frac{63.55 \text{ g Cu}}{1 \cancel{\text{mol Cu}}} = 0.790 \text{ g Cu}$$

Is the Answer Reasonable? As before, we round all numbers to one significant figure to estimate the answer. To be sure the problem is set up correctly, cancel the units as we did in the solution.

$$\text{g Cu} = 2\text{ A} \times 20\text{ min} \times \frac{60\text{ s}}{1\text{ min}} \times \frac{1\text{ mol } e^-}{10 \times 10^4\text{ A s}} \times \frac{1\text{ mol Cu}}{2\text{ mol } e^-} \times \frac{60\text{ g Cu}}{1\text{ mol Cu}}$$

$$= \frac{40 \times 3600}{200{,}000} = \frac{40 \times 0.36}{20} = 0.72\text{ g Cu}$$

This is very close to our answer, and we are even more confident that the calculation was correct when we supply the cancellation of units to our estimate.

Example 20.14
Calculations Related to Electrolysis

Electrolysis provides a useful way to deposit a thin metallic coating on an electrically conducting surface. This technique is called electroplating. How much time would it take, in minutes, to deposit 0.500 g of metallic nickel on a metal object using a current of 3.00 A? The nickel is reduced from the +2 oxidation state.

Analysis: This problem is essentially the reverse of Example 20.13. We will perform a stoichiometric calculation starting with the given mass of nickel and ending with the coulombs needed.

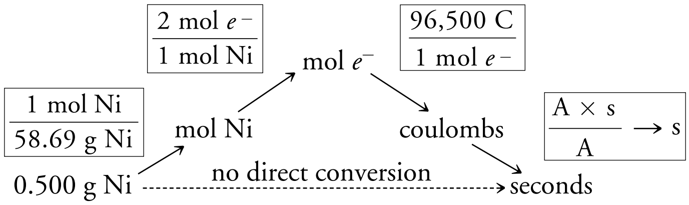
Assembling the Tools: We should be very familiar with converting mass to moles; the next step requires a balanced chemical equation. Because the nickel is reduced to the free metal from the +2 state, we can write

$$\text{Ni}^{2+} + 2e^- \longrightarrow \text{Ni}(s)$$

This gives the relationship

$$1\text{ mol Ni} \Leftrightarrow 2\text{ mol } e^-$$

which allows us to calculate the number of moles of electrons required. This, in turn, is used with the tool for the Faraday constant to determine the number of coulombs required. Equation 20.9 tells us that this is the product of amperes and seconds; so we can calculate the time needed to deposit the metal. The diagram below isolates our sequence of steps that can also be deduced from Figure 20.22.



$\frac{2\text{ mol } e^-}{1\text{ mol Ni}}$
mol e^-
$\frac{96{,}500\text{ C}}{1\text{ mol } e^-}$
$\frac{1\text{ mol Ni}}{58.69\text{ g Ni}}$
mol Ni
coulombs
$\frac{\text{A} \times \text{s}}{\text{A}} \rightarrow \text{s}$
0.500 g Ni
no direct conversion
seconds

Solution: First, we calculate the number of moles of electrons required (keeping at least one extra significant figure).

$$0.500\,\cancel{\text{g Ni}} \times \left(\frac{1\ \cancel{\text{mol Ni}}}{58.69\ \cancel{\text{g Ni}}}\right) \times \left(\frac{2\text{ mol } e^-}{1\ \cancel{\text{mol Ni}}}\right) = 0.01704\text{ mol } e^-$$

In stepwise calculations we usually carry one or more extra significant figures to minimize rounding errors.

Then we calculate the number of coulombs needed.

$$0.01704\ \cancel{\text{mol } e^-} \times \left(\frac{9.65 \times 10^4\ \text{C}}{1\ \cancel{\text{mol } e^-}}\right) = 1.644 \times 10^3\ \text{C}$$

$$= 1.644 \times 10^3\ \text{A s}$$

■ Once we've calculated the number of coulombs required, we can calculate the time required if we know the current, or the current needed to perform the electrolysis in a given time.

This tells us that the product of current multiplied by time equals 1.644×10^3 A s. The current is 3.00 A. Dividing 1.644×10^3 A s by 3.00 A gives the time required in seconds, which we then convert to minutes.

$$\left(\frac{1.644 \times 10^3\ \cancel{\text{A}}\ \cancel{\text{s}}}{3.00\ \cancel{\text{A}}}\right) \times \left(\frac{1\ \text{min}}{60\ \cancel{\text{s}}}\right) = 9.133\ \text{min}$$

Properly rounded, this becomes 9.13 min. We could also have combined these calculations in a single string of conversion factors.

$$0.500\ \cancel{\text{g Ni}} \times \frac{1\ \cancel{\text{mol Ni}}}{58.69\ \cancel{\text{g Ni}}} \times \frac{2\ \cancel{\text{mol}\ e^-}}{1\ \cancel{\text{mol Ni}}} \times \frac{9.65 \times 10^4\ \cancel{\text{A}}\ \cancel{\text{s}}}{1\ \cancel{\text{mol}\ e^-}} \times \frac{1}{3.00\ \cancel{\text{A}}} \times \frac{1\ \text{min}}{60\ \cancel{\text{s}}} = 9.13\ \text{min}$$

■ **Is the Answer Reasonable?** As in the preceding example, let's round all numbers to one digit as

$$\text{min} = 0.5\ \text{g Ni} \times \frac{1\ \text{mol Ni}}{60\ \text{g Ni}} \times \frac{2\ \text{mol}\ e^-}{1\ \text{mol Ni}} \times \frac{10 \times 10^4\ \text{A s}}{1\ \text{mol}\ e^-} \times \frac{1}{3\ \text{A}} \times \frac{1\ \text{min}}{60\ \text{s}}$$

$$= \frac{100{,}000}{3{,}600 \times 3} = \frac{100{,}000}{10{,}000} = 10\ \text{min}$$

This result, along with the proper cancellation of units, indicates that our setup and calculations were correct.

Practice Exercises

20.25 | How many moles of hydroxide ion will be produced at the cathode during the electrolysis of water with a current of 4.00 A for a period of 3.00 minutes? The cathode reaction is

$$2e^- + 2H_2O \longrightarrow H_2 + 2OH^-$$

(*Hint*: The stepwise diagram in Example 20.14 will be helpful.)

20.26 | How many minutes will it take for a current of 10.0 A to deposit 3.00 g of gold from a solution of $AuCl_3$?

20.27 | What current must be supplied to deposit 3.00 g of gold from a solution of $AuCl_3$ in 20.0 min?

20.28 | Suppose the solutions in the galvanic cell depicted in Figure 20.2 (page 920) have a volume of 125 mL and suppose the cell is operated for a period of 1.25 hr with a constant current of 0.100 A flowing through the external circuit. By how much will the concentration of the copper ion increase during this time period?

20.9 | Practical Applications of Electrolysis

Electrochemistry has many applications both in science and in our everyday lives. In this limited space, we can only touch on some of the more common and important examples of the industrial uses of electrolysis.

Industrial Applications

Besides being a useful tool in the chemistry laboratory, electrolysis has many important industrial applications. In this section we will briefly examine the chemistry of electroplating and the production of some of our most common chemicals.

Electroplating

Electroplating, which was mentioned in Examples 20.13 and 20.14, is a procedure in which electrolysis is used to apply a thin (generally 0.03 to 0.05 mm thick) ornamental or protective coating of one metal over another. It is a common technique for improving the appearance and durability of metal objects. For instance, a thin, shiny coating of metallic chromium is applied over steel objects to make them attractive and to prevent rusting.

The exact composition of the electroplating bath varies, depending on the metal to be deposited, and it can affect the appearance and durability of the finished surface. For example, silver deposited from a solution of silver nitrate ($AgNO_3$) does not stick to other metal surfaces very well. However, if it is deposited from a solution of silver cyanide containing $Ag(CN)_2^-$, the coating adheres well and is bright and shiny. Other metals that are electroplated from a cyanide bath are gold and cadmium. Nickel, which can also be applied as a protective coating, is plated from a nickel sulfate solution, and chromium is plated from a chromic acid (H_2CrO_4) solution.

This motorcycle sparkles with chrome plating that was deposited by electrolysis. The shiny, hard coating of chromium is both decorative and a barrier to corrosion. *(Syracuse Newspapers/The Image Works)*

■ Aluminum is used today as a structural metal, in alloys, and in such products as aluminum foil, electrical wire, window frames, and kitchen pots and pans.

Production of Aluminum

Aluminum is a useful but highly reactive metal. It is so difficult to reduce that ordinary metallurgical methods for obtaining it do not work. Early efforts to produce aluminum by electrolysis failed because its anhydrous halide salts (those with no water of hydration) are difficult to prepare and are volatile, tending to evaporate rather than melt. On the other hand, its oxide, Al_2O_3, has such a high melting point (over 2000 °C) that no practical method of melting it could be found.

In 1886, Charles M. Hall discovered that Al_2O_3 dissolves in the molten form of a mineral called cryolite, Na_3AlF_6, to give a conducting mixture with a relatively low melting point from which aluminum could be produced electrolytically. The process was also discovered by Paul Héroult in France at nearly the same time, and today this method for producing aluminum is usually called the **Hall–Héroult process** (see Figure 20.23). Purified aluminum oxide, which is obtained from an ore called *bauxite,* is dissolved in molten cryolite in which the oxide dissociates to give Al^{3+} and O^{2-} ions. At the cathode, aluminum ions are reduced to produce the free metal, which forms as a layer of molten aluminum below the less dense solvent. At the carbon anodes, the oxide ion is oxidized to give free O_2.

$$
\begin{array}{rlr}
Al^{3+} + 3e^- & \longrightarrow Al(l) & \text{(cathode)} \\
2O^{2-} & \longrightarrow O_2(g) + 4e^- & \text{(anode)} \\
\hline
4Al^{3+} + 6O^{2-} & \longrightarrow 4Al(l) + 3O_2(g) & \text{(cell reaction)}
\end{array}
$$

The oxygen formed at the anode attacks the carbon electrodes (producing CO_2), so the electrodes must be replaced frequently.

The production of aluminum consumes enormous amounts of electrical energy and is therefore very costly, not only in terms of dollars but also in terms of energy resources. For this reason, recycling of aluminum has a high priority as we seek to minimize our use of energy.

Molten Al can be drawn off here.

Figure 20.23 | **Production of aluminum by electrolysis.** In the apparatus used to produce aluminum electrolytically by the Hall–Héroult process, Al_2O_3 is dissolved in molten cryolite, Na_3AlF_6. The Al^{3+} is reduced to metallic Al, and O^{2-} is oxidized to O_2, which reacts with the carbon anodes to give CO_2. Periodically, molten aluminum is drawn off at the bottom of the cell and additional Al_2O_3 is added to the cryolite. The carbon anodes also must be replaced from time to time as they are consumed by their reaction with O_2.

Production of Sodium

Sodium is prepared by the electrolysis of molten sodium chloride (see Section 20.6). The metallic sodium and the chlorine gas that form must be kept apart or they will react violently and re-form NaCl. A specialized apparatus called a **Downs cell** accomplishes this separation.

Both sodium and chlorine are commercially important. Chlorine is used largely to manufacture plastics such as polyvinyl chloride (PVC), many solvents, and industrial chemicals. A small percentage of the annual chlorine production is used to chlorinate drinking water.

- PVC is used to make a large variety of products, from raincoats to wire insulation to pipes and conduits for water and sanitary systems. In the United States, the annual demand for PVC plastics is about 15 billion pounds.

Sodium has been used in the manufacture of tetraethyl lead, an octane booster for gasoline that has been phased out in the United States but is still used in many other countries. Sodium is also used in the production of energy-efficient sodium vapor lamps, which give street lights and other commercial lighting a bright yellow-orange color.

Refining Copper

When copper is first obtained from its ore, it is about 99% pure. The impurities—mostly silver, gold, platinum, iron, and zinc—decrease the electrical conductivity of the copper enough that even 99% pure copper must be further refined before it can be used in electrical wire.

Copper refining. Copper cathodes, 99.96% pure, are pulled from the electrolytic refining tanks at Kennecott's Utah copper refinery. It takes about 28 days for the impure copper anodes to dissolve and deposit the pure metal on the cathodes. *(Courtesy James Brady)*

The impure copper is used as the anode in an electrolysis cell that contains a solution of copper sulfate and sulfuric acid as the electrolyte (see Figure 20.24). The cathode is a thin sheet of very pure copper. When the cell is operated at the correct voltage, only copper and impurities more easily oxidized than copper (iron and zinc) dissolve at the anode. The less active metals simply fall off the electrode and settle to the bottom of the container. At the cathode, copper ions are reduced, but the zinc ions and iron ions remain in solution because they are more difficult to reduce than copper. Gradually, the impure copper anode dissolves and the copper cathode, about 99.96% pure, grows larger. The accumulating sludge—called anode mud—is removed periodically, and the value of the silver, gold, and platinum recovered from it virtually pays for the entire refining operation.

- Copper refining provides one-fourth of the silver and one-eighth of the gold produced annually in the United States.

Electrolysis of Brine

One of the most important commercial electrolysis reactions is the electrolysis of concentrated aqueous sodium chloride solutions called **brine**. Water is much more easily reduced than sodium ions, so H_2 forms at the cathode.

$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad \text{(cathode)}$$

As we noted earlier, even though water is more easily oxidized than chloride ions, complicating factors at the electrode surface actually allow chloride ions to be oxidized more readily than water. At the anode, therefore, we observe the formation of Cl_2.

$$2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^- \qquad \text{(anode)}$$

Figure 20.24 | **Purification of copper by electrolysis.** Impure copper anodes dissolve and pure copper is deposited on the cathodes. Metals less easily oxidized than copper settle to the bottom of the apparatus as "anode mud," while metals less easily reduced than copper remain in solution.

The net cell reaction is therefore

$$2\text{Cl}^-(aq) + 2\text{H}_2\text{O}(l) \longrightarrow \text{H}_2(g) + \text{Cl}_2(g) + 2\text{OH}^-(aq)$$

If we include the sodium ion, already in the solution as a spectator ion and not involved in the electrolysis directly, we can see why this is such an important reaction.

$$\underbrace{2\text{Na}^+(aq) + 2\text{Cl}^-(aq)}_{2\text{NaCl}(aq)} + 2\text{H}_2\text{O} \xrightarrow{\text{electrolysis}} \text{H}_2(g) + \text{Cl}_2(g) + \underbrace{2\text{Na}^+(aq) + 2\text{OH}^-(aq)}_{2\text{NaOH}(aq)}$$

Thus, the electrolysis converts inexpensive salt to valuable chemicals: H_2, Cl_2, and NaOH. The hydrogen is used to make other chemicals, including hydrogenated vegetable oils. The chlorine is used for the purposes mentioned earlier. Among the uses of sodium hydroxide, one of industry's most important bases, are the manufacture of soap and paper, the neutralization of acids in industrial reactions, and the purification of aluminum ores.

■ Sodium hydroxide is commonly known as *lye* or *caustic soda*.

In the industrial electrolysis of brine, it is necessary to capture the H_2 and Cl_2 separately to prevent them from mixing and reacting (explosively). Second, the NaOH from the reaction is contaminated with unreacted NaCl. Third, if Cl_2 is left in the presence of NaOH, the solution becomes contaminated by hypochlorite ions (OCl^-), which form when Cl_2 reacts with OH^-.

$$\text{Cl}_2(g) + 2\text{OH}^-(aq) \longrightarrow \text{Cl}^-(aq) + \text{OCl}^-(aq) + \text{H}_2\text{O}$$

In one manufacturing operation, however, the Cl_2 is not removed as it forms, and its reaction with hydroxide ion is used to manufacture aqueous sodium hypochlorite. For this purpose, the solution is stirred vigorously during the electrolysis so that very little Cl_2 escapes. As a result, a stirred solution of NaCl gradually changes during electrolysis to a solution of NaOCl, a dilute, 5% solution of which is sold as liquid laundry bleach (e.g., Clorox).

Most of the pure NaOH manufactured today is made in an apparatus called a **diaphragm cell**. The design varies somewhat, but Figure 20.25 illustrates its basic features. The cell consists of an iron wire mesh cathode that encloses a porous asbestos shell—

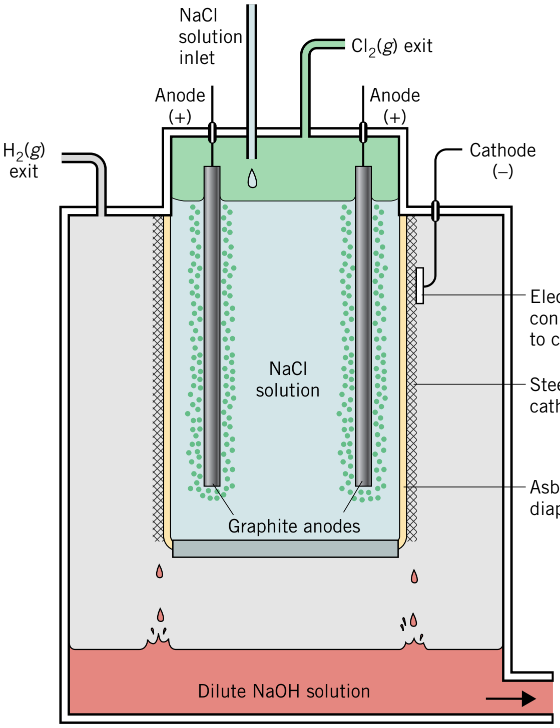

Figure 20.25 | **A diaphragm cell used in the commercial production of NaOH by the electrolysis of aqueous NaCl.** This is a cross section of a cylindrical cell in which the NaCl solution is surrounded by an asbestos diaphragm supported by a steel mesh cathode. *(From J. E. Brady and G. E. Humiston,* General Chemistry: Principles and Structure, *5th ed. Copyright © 1986, John Wiley & Sons, New York. Used by permission.)*

the diaphragm. The NaCl solution is added to the top of the cell and seeps slowly through the diaphragm. When it contacts the iron cathode, hydrogen is evolved and is pumped out of the surrounding space. The solution, now containing dilute NaOH, drips off the cell into the reservoir below. Meanwhile, within the cell, chlorine is generated at the anodes. Because there is no OH^- near the anodes, the Cl_2 can't react to form the OCl^- ion and simply bubbles out of the solution and is captured as illustrated in the figure.

Summary

Galvanic Cells. A **galvanic cell** is composed of two **half-cells,** each containing an **electrode** in contact with an electrolyte reactant. A spontaneous redox reaction is thus divided into separate oxidation and reduction half-reactions, with the electron transfer occurring through an external electrical circuit. Reduction occurs at the **cathode;** oxidation occurs at the **anode.** In a galvanic cell, the cathode is positively charged and the anode is negatively charged. The half-cells must be connected electrolytically by a **salt bridge** to complete the electrical circuit, which permits electrical neutrality to be maintained by allowing cations to move toward the cathode and anions toward the anode.

The **potential** (expressed in volts) produced by a cell is equal to the **standard cell potential** when all ion concentrations are 1.00 *M* and the partial pressures of any gases involved equal 1.00 atm and the temperature is 25.0 °C. The **standard cell potential** is the difference between the **standard reduction potentials** of the half-cells. In the spontaneous reaction, the half-cell with the higher standard reduction potential undergoes reduction and forces the other to undergo oxidation. The standard reduction potentials of isolated half-cells can't be measured, but values are assigned by choosing the **hydrogen electrode** as a reference electrode; its standard reduction potential is assigned a value of exactly 0.00 V. Species more easily reduced than H^+ have positive standard reduction potentials; those less easily reduced have negative standard reduction potentials. Standard reduction potentials are used to calculate $\boldsymbol{E^\circ_{\text{cell}}}$. Standard reduction potentials can be used to predict whether or not a redox reaction will be spontaneous, whether or not the reaction is carried out in a galvanic cell. Often, standard reduction potentials can be used to determine the products of electrolysis reactions. Since reduction potentials under nonstandard conditions are often numerically close to standard reduction potentials, we can usually use standard reduction potentials to make predictions about reactions with nonstandard conditions.

Thermodynamics and Cell Potentials. The values of ΔG° and K_c for a reaction can be calculated from E°_{cell}. They all involve the **faraday,** $\mathscr{F}$, a constant equal to the number of **coulombs (C)** of charge per mole of electrons ($1\mathscr{F} = 96{,}485$ C/mol e^-). The **Nernst equation** relates the cell potential to the standard cell potential and the reaction quotient. It is used to calculate the cell potential under nonstandard conditions. If the cell potential is measured, the Nernst equation may be used to determine concentrations.

Electrolysis. In an **electrolytic cell,** a flow of electricity causes an otherwise nonspontaneous reaction to occur. A negatively charged **cathode** causes reduction of one reactant and a positively charged **anode** causes oxidation of another. Ion movement instead of electron transport occurs in the electrolyte. The electrode reactions are determined by which species is most easily reduced and which is most easily oxidized, but in aqueous solutions complex surface effects at the electrodes can alter the natural order. In the electrolysis of water, an electrolyte must be present to maintain electrical neutrality at the electrodes.

Quantitative Aspects of Electrochemical Reactions. The product of current (**amperes**) and time (seconds) gives coulombs. This relationship and the half-reactions that occur at the anode or cathode permit us to relate the amount of chemical change to measurements of current and time.

Practical Galvanic Cells. The **lead storage battery** and the **nickel–cadmium (nicad) battery** are **secondary cells** and are rechargeable. The state of charge of the lead storage battery can be tested with a **hydrometer**, which measures the density of the sulfuric acid electrolyte. The **zinc–manganese dioxide cell** (the **Leclanché cell** or common dry cell) and the common **alkaline battery** (which uses essentially the same reactions as the less expensive dry cell) are **primary cells** and are not rechargeable. The rechargeable **nickel–metal hydride** (Ni–MH) battery uses hydrogen contained in a metal alloy as its anode reactant and has a higher **energy density** than the nicad battery. Primary **lithium–manganese dioxide cells** and rechargeable **lithium ion cells** produce a large cell potential and have a very large energy density. Lithium ion cells store and release energy by transferring lithium ions between electrodes where the Li^+ are **intercalated** between layers of atoms in the electrode materials. **Fuel cells**, which have high thermodynamic efficiencies, are able to provide continuous power because they consume fuel that can be fed continuously. **Photovoltaic cells** are based on semiconductor technology where the junction between a **p-type** and an **n-type** semiconductor produces a device called a **diode** that allows electrons to flow in only one direction. Once photons separate an electron from the semiconductor material, the properties of a diode make it easier for electrons to flow through an external circuit.

Applications of Electrolysis. **Electroplating,** the production of aluminum, the **refining** of copper, and the electrolysis of molten and aqueous sodium chloride are examples of practical applications of electrolysis.

Tools for Problem Solving

The following tools were introduced in this chapter. Study them carefully so you can select the appropriate tool when needed.

Electrode names and reactions (page 921)

Scientists have agreed to name electrodes based on the reaction that occurs. The **cathode** is the electrode at which reduction (electron gain) occurs. The **anode** is the electrode at which oxidation (electron loss) occurs.

Standard reduction potentials used to calculate E°_{cell} (page 925)

In a galvanic cell, the difference between two standard reduction potentials equals the standard cell potential

$$E^\circ_{\text{cell}} = E^\circ_{\text{reduction}} - E^\circ_{\text{oxidation}}$$

Standard cell potentials are always positive, and the reaction that gives us a positive standard cell potential will be a spontaneous reaction at standard state (page 934). Comparing standard reduction potentials also lets us predict the electrode reactions in electrolysis (page 956).

Faraday constant (page 936)

Besides being a constant in the equations below, the Faraday constant allows us to relate coulombs (obtained from the product of current and time) to moles of chemical change in electrochemical reactions.

$$1\mathscr{F} = 96{,}485.340 \text{ C/mol } e^-$$

Standard cell potentials are related to thermodynamic quantities

The relationship between the cell potential E_{cell} and the free energy, ΔG is: $\Delta G = -n\mathscr{F}E$ (page 937)
The relationship between the standard cell potential, E°_{cell}, and the standard free energy, ΔG° is: $\Delta G^\circ = -n\mathscr{F}E^\circ$ (page 937).

The relationship between the standard cell potential, E°_{cell}, and the equilibrium constant, K_c, is: $E^\circ_{\text{cell}} = \dfrac{RT}{n\mathscr{F}}\ln K_c$ (page 938).

Standard cell potentials are also needed to solve the Nernst equation (below) to relate concentrations of species in galvanic cells to the cell potential.

Nernst equation (page 940)

The Nernst equation lets us relate the cell potential, E_{cell}, the standard cell potential, E°_{cell}, and concentration data.

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{RT}{n\mathscr{F}}\ln Q$$

We can also calculate the concentration of a species in solution from E°_{cell} and a measured value for E_{cell} (page 943).

Coulombs are related to current in amperes and time in seconds (page 959)

Coulombs, C, can be experimentally determined as the current, A, multiplied by time, t, in seconds. Combined with the faraday, the moles of electrons can be determined.

$$\text{C} = \text{A} \times t$$

PLUS = *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com.** ILW = An Interactive Learningware solution is available for this problem. Review Questions

Galvanic Cells

20.1 What is a galvanic cell? What is a half-cell?

20.2 What is the function of a *salt bridge*?

20.3 In the copper–silver cell, why must the Cu^{2+} and Ag^+ solutions be kept in separate containers?

20.4 Which redox processes take place at the anode and cathode in a galvanic cell? What is the sign of the electrical charges on the anode and cathode in a galvanic cell?

20.5 In a galvanic cell, do electrons travel from anode to cathode, or from cathode to anode? Explain.

20.6 Explain how the movement of the ions relative to the electrodes is the same in both galvanic and electrolytic cells.

20.7 Aluminum will displace tin from solution according to the equation $2Al(s) + 3Sn^{2+}(aq) \longrightarrow 2Al^{3+}(aq) + 3Sn(s)$. What would be the individual half-cell reactions if this were the cell reaction for a galvanic cell? Which metal would be the anode and which the cathode?

Cell Potentials and Reduction Potentials

20.8 What is the difference between a *cell potential* and a *standard cell potential*?

20.9 How are standard reduction potentials combined to give the standard cell potential for a spontaneous reaction?

20.10 Describe the hydrogen electrode. What is the value of its standard reduction potential?

20.11 What do the positive and negative signs of reduction potentials tell us?

20.12 If $E°_{Cu^{2+}}$ had been chosen as the standard reference electrode and had been assigned a potential of 0.00 V, what would the reduction potential of the hydrogen electrode be relative to it?

20.13 If you set up a galvanic cell using metals not found in Table 20.1, what experimental information will tell you which is the anode and which is the cathode in the cell?

Using Standard Reduction Potentials

20.14 Compare Table 6.3 with Table 20.1. What can you say about the basis for the activity series for metals?

20.15 Make a sketch of a galvanic cell for which the cell notation is

$$Fe(s) \,|\, Fe^{3+}(aq) \,||\, Ag^+(aq) \,|\, Ag(s)$$

(a) Label the anode and the cathode.

(b) Indicate the charge on each electrode.

(c) Indicate the direction of electron flow in the external circuit.

(d) Write the equation for the net cell reaction.

20.16 Make a sketch of a galvanic cell in which inert platinum electrodes are used in the half-cells for the system

$$Pt(s) \,|\, Fe^{2+}(aq), Fe^{3+}(aq) \,||\, Br_2(aq), Br^-(aq) \,|\, Pt(s)$$

Label the diagram and indicate the composition of the electrolytes in the two cell compartments. Show the signs of the electrodes and label the anode and cathode. Write the equation for the net cell reaction.

Cell Potentials and Thermodynamics

20.17 Write the equation that relates the standard cell potential to the standard free energy change for a reaction.

20.18 What is the equation that relates the equilibrium constant to the cell potential?

20.19 Show how the equation that relates the equilibrium constant to the cell potential (Equation 20.7) can be derived from the Nernst equation (Equation 20.8).

The Effect of Concentration on Cell Potential

20.20 The cell reaction during the discharge of a lead storage battery is

$$Pb(s) + PbO_2(s) + 2H^+(aq) + 2HSO_4^-(aq) \longrightarrow 2PbSO_4(s) + 2H_2O$$

The standard cell potential is 2.05 V. What is the correct form of the Nernst equation for this reaction at 25 °C?

20.21 What is a concentration cell? Why is the $E°_{cell}$ for such a cell equal to zero?

Practical Galvanic Cells

20.22 What are the anode and cathode reactions during the discharge of a lead storage battery? How can a battery produce a potential of 12 V if the cell reaction has a standard potential of only 2 V?

20.23 What are the anode and cathode reactions during the charging of a lead storage battery?

20.24 How is a hydrometer constructed? How does it measure density? Why can a hydrometer be used to check the state of charge of a lead storage battery?

20.25 What reactions occur at the electrodes in the ordinary dry cell?

20.26 What chemical reactions take place at the electrodes in an alkaline dry cell?

20.27 Give the half-cell reactions and the cell reaction that take place in a nicad battery during discharge. What are the reactions that take place during the charging of the cell?

20.28 How is hydrogen held as a reactant in a nickel–metal hydride battery? Write the chemical formula for a typical alloy used in this battery. What is the electrolyte?

20.29 What are the anode, cathode, and net cell reactions that take place in a nickel–metal hydride battery during discharge? What are the reactions when the battery is charged?

20.30 Give two reasons why lithium is such an attractive anode material for use in a battery. What are the problems associated with using lithium for this purpose?

20.31 What are the electrode materials in a typical primary lithium cell? Write the equations for the anode, cathode, and cell reactions.

20.32 What are the electrode materials in a typical lithium ion cell? Explain what happens when the cell is charged. Explain what happens when the cell is discharged.

20.33 Write the cathode, anode, and net cell reaction in a hydrogen–oxygen fuel cell.

20.34 What advantages do fuel cells offer over conventional means of obtaining electrical power by the combustion of fuels?

Electrolysis

20.35 What electrical charges do the anode and the cathode carry in an electrolytic cell? What does the term *inert electrode* mean?

20.36 Why must electrolysis reactions occur at the electrodes in order for electrolytic conduction to continue?

20.37 Why must NaCl be melted before it is electrolyzed to give Na and Cl_2? Write the anode, cathode, and overall cell reactions for the electrolysis of molten NaCl.

20.38 Write half-reactions for the oxidation and the reduction of water.

20.39 What happens to the pH of the solution near the cathode and anode during the electrolysis of K_2SO_4? What function does K_2SO_4 serve in the electrolysis of a K_2SO_4 solution?

Stoichiometric Relationships in Electrolysis

20.40 What is a *faraday*? What relationships relate faradays to current and time measurements?

20.41 Using the same current, which will require the greater length of time, depositing 0.10 mol Cu from a Cu^{2+} solution, or depositing 0.10 mol of Cr from a Cr^{3+} solution? Explain your reasoning.

20.42 An electric current is passed through two electrolysis cells connected in series (so the same amount of current passes through each of them). One cell contains Cu^{2+} and the other contains Ag^+. In which cell will the larger number of moles of metal be deposited? Explain your answer.

20.43 An electric current is passed through two electrolysis cells connected in series (so the same amount of current passes through each of them). One cell contains Cu^{2+} and the other contains Fe^{2+}. In which cell will the greater mass of metal be deposited? Explain your answer.

Applications of Electrolysis

20.44 What is *electroplating*? Sketch an apparatus to electroplate silver.

20.45 Describe the Hall–Héroult process for producing metallic aluminum. What half-reaction occurs at the anode? What half-reaction occurs at the cathode? What is the overall cell reaction?

20.46 In the Hall–Héroult process, why must the carbon anodes be replaced frequently?

20.47 How is metallic sodium produced? Write equations for the anode and cathode reactions. What are some uses of metallic sodium?

20.48 Describe the electrolytic refining of copper. What economic advantages offset the cost of electricity for this process? What chemical reactions occur at (a) the anode and (b) the cathode?

20.49 Describe the electrolysis of aqueous sodium chloride. How do the products of the electrolysis compare for stirred and unstirred reactions? Write chemical equations for the reactions that occur at the electrodes.

Review Problems

Cell Notation

20.50 Write the half-reactions and the balanced cell reaction for the following galvanic cells.

(a) $Cd(s) | Cd^{2+}(aq) \| Au^{3+}(aq) | Au(s)$

(b) $Fe(s) | Fe^{2+}(aq) \| Br_2(aq), Br^-(aq) | Pt(s)$

(c) $Cr(s) | Cr^{3+}(aq) \| Cu^{2+}(aq) | Cu(s)$

OH **20.51** Write the half-reactions and the balanced cell reaction for the following galvanic cells.

(a) $Zn(s) | Zn^{2+}(aq) \| Cr^{3+}(aq) | Cr(s)$

(b) $Pb(s), PbSO_4(s) | HSO_4^-(aq) \| H^+(aq), HSO_4^-(aq) | PbO_2(s), PbSO_4(s)$

(c) $Mg(s) | Mg^{2+}(aq) \| Sn^{2+}(aq) | Sn(s)$

20.52 Write the cell notation for the following galvanic cells. For half-reactions in which all the reactants are in solution or are gases, assume the use of inert platinum electrodes.

(a) $NO_3^-(aq) + 4H^+(aq) + 3Fe^{2+}(aq) \longrightarrow 3Fe^{3+}(aq) + NO(g) + 2H_2O$

(b) $Cl_2(g) + 2Br^-(aq) \longrightarrow Br_2(aq) + 2Cl^-(aq)$

(c) $Au^{3+}(aq) + 3Ag(s) \longrightarrow Au(s) + 3Ag^+(aq)$

20.53 Write the cell notation for the following galvanic cells. For half-reactions in which all the reactants are in solution or are gases, assume the use of inert platinum electrodes.

(a) $Cd^{2+}(aq) + Fe(s) \longrightarrow Cd(s) + Fe^{2+}(aq)$

(b) $NiO_2(s) + 4H^+(aq) + 2Ag(s) \longrightarrow Ni^{2+}(aq) + 2H_2O + 2Ag^+(aq)$

(c) $Mg(s) + Cd^{2+}(aq) \longrightarrow Mg^{2+}(aq) + Cd(s)$

Reduction Potentials

20.54 For each pair of substances, use Table 20.1 to choose the better reducing agent.

(a) $Sn(s)$ or $Ag(s)$

(b) $Cl^-(aq)$ or $Br^-(aq)$

(c) $Co(s)$ or $Zn(s)$

(d) $I^-(aq)$ or $Au(s)$

20.55 For each pair of substances, use Table 20.1 to choose the better oxidizing agent.

(a) $NO_3^-(aq)$ or $MnO_4^-(aq)$

(b) $Au^{3+}(aq)$ or $Co^{2+}(aq)$

(c) $PbO_2(s)$ or $Cl_2(g)$

(d) $NiO_2(s)$ or $HOCl(aq)$

OH **20.56** Use the data in Table 20.1 to calculate the standard cell potential for each of the following reactions:

(a) $NO_3^-(aq) + 4H^+(aq) + 3Fe^{2+}(aq) \longrightarrow 3Fe^{3+}(aq) + NO(g) + 2H_2O$

(b) $Br_2(aq) + 2Cl^-(aq) \longrightarrow Cl_2(g) + 2Br^-(aq)$

(c) $Au^{3+}(aq) + 3Ag(s) \longrightarrow Au(s) + 3Ag^+(aq)$

20.57 Use the data in Table 20.1 to calculate the standard cell potential for each of the following reactions:

(a) $Cd^{2+}(aq) + Fe(s) \longrightarrow Cd(s) + Fe^{2+}(aq)$

(b) $NiO_2(s) + 4H^+(aq) + 2Ag(s) \longrightarrow Ni^{2+}(aq) + 2H_2O + 2Ag^+(aq)$

(c) $Mg(s) + Cd^{2+}(aq) \longrightarrow Mg^{2+}(aq) + Cd(s)$

20.58 From the positions of the half-reactions in Table 20.1, determine whether the following reactions are spontaneous under standard state conditions.

(a) $2Au^{3+} + 6I^- \longrightarrow 3I_2 + 2Au$

(b) $H_2SO_3 + H_2O + Br_2 \longrightarrow 4H^+ + SO_4^{2-} + 2Br^-$

(c) $3Ca + 2Cr^{3+} \longrightarrow 2Cr + 3Ca^{2+}$

20.59 Use the data in Table 20.1 to determine which of the following reactions should occur spontaneously under standard state conditions.

(a) $Br_2 + 2Cl^- \longrightarrow Cl_2 + 2Br^-$

(b) $3Fe^{2+} + 2NO + 4H_2O \longrightarrow 3Fe + 2NO_3^- + 8H^+$

(c) $Ni^{2+} + Fe \longrightarrow Fe^{2+} + Ni$

ILW **20.60** From the half-reactions below, determine the cell reaction and standard cell potential.

$$BrO_3^- + 6H^+ + 6e^- \rightleftharpoons Br^- + 3H_2O \qquad E^\circ_{BrO_3^-} = 1.44 \text{ V}$$

$$I_2 + 2e^- \rightleftharpoons 2I^- \qquad E^\circ_{I_2} = 0.54 \text{ V}$$

20.61 What is the standard cell potential and the net reaction in a galvanic cell that has the following half-reactions?

$$MnO_2 + 4H^+ + 2e^- \rightleftharpoons Mn^{2+} + 2H_2O \qquad E^\circ_{MnO_2} = 1.23 \text{ V}$$

$$PbCl_2 + 2e^- \rightleftharpoons Pb + 2Cl^- \qquad E^\circ_{PbCl_2} = -0.27 \text{ V}$$

OH **20.62** What will be the spontaneous reaction among H_2SO_3, $S_2O_3^{2-}$, HOCl, and Cl_2? The half-reactions involved are

$$2H_2SO_3 + 2H^+ + 4e^- \rightleftharpoons S_2O_3^{2-} + 3H_2O \qquad E^\circ_{H_2SO_3} = 0.40 \text{ V}$$

$$2HOCl + 2H^+ + 2e^- \rightleftharpoons Cl_2 + 2H_2O \qquad E^\circ_{HOCl} = 1.63 \text{ V}$$

20.63 What will be the spontaneous reaction among Br_2, I_2, Br^-, and I^-?

20.64 Will the following reaction occur spontaneously under standard state conditions?

$$SO_4^{2-} + 4H^+ + 2I^- \longrightarrow H_2SO_3 + I_2 + H_2O$$

Use E°_{cell} calculated from data in Table 20.1 to answer this question.

20.65 Determine whether the reaction

$$S_2O_8^{2-} + Ni(OH)_2 + 2OH^- \longrightarrow 2SO_4^{2-} + NiO_2 + 2H_2O$$

will occur spontaneously under standard state conditions. Use E°_{cell} calculated from the data below to answer the question.

$$NiO_2 + 2H_2O + 2e^- \rightleftharpoons Ni(OH)_2 + 2OH^- \qquad E^\circ_{NiO_2} = 0.49 \text{ V}$$

$$S_2O_8^{2-} + 2e^- \rightleftharpoons 2SO_4^{2-} \qquad E^\circ_{S_2O_8^{2-}} = 2.01 \text{ V}$$

Cell Potentials and Thermodynamics

ILW **20.66** Calculate ΔG° for the following reaction *as written*

$$2Br^- + I_2 \longrightarrow 2I^- + Br_2$$

OH **20.67** Calculate ΔG° for the reaction

$$2MnO_4^- + 6H^+ + 5HCHO_2 \longrightarrow 2Mn^{2+} + 8H_2O + 5CO_2$$

for which $E^\circ_{cell} = 1.69$ V.

20.68 Given the following half-reactions and their standard reduction potentials,

$$2ClO_3^- + 12H^+ + 10e^- \rightleftharpoons Cl_2 + 6H_2O \qquad E^\circ_{ClO_3^-} = 0.47 \text{ V}$$

$$S_2O_8^{2-} + 2e^- \rightleftharpoons 2SO_4^{2-} \qquad E^\circ_{S_2O_8^{2-}} = 2.01 \text{ V}$$

calculate **(a)** E°_{cell}, **(b)** ΔG° for the cell reaction, and **(c)** the value of K_c for the cell reaction.

20.69 Calculate K_c for the system $Ni^{2+} + Co \rightleftharpoons Ni + Co^{2+}$. Use the data in Table 20.1 and assume $T = 298$ K.

20.70 The system $2AgI + Sn \rightleftharpoons Sn^{2+} + 2Ag + 2I^-$ has a calculated $E^\circ_{cell} = -0.015$ V. What is the value of K_c for this system?

20.71 Determine the value of K_c at 25 °C for the reaction

$$2H_2O + 2Cl_2 \rightleftharpoons 4H^+ + 4Cl^- + O_2$$

Cell Potentials and Concentration

20.72 The cell reaction

$$NiO_2(s) + 4H^+(aq) + 2Ag(s) \longrightarrow Ni^{2+}(aq) + 2H_2O + 2Ag^+(aq)$$

has $E^\circ_{cell} = 2.48$ V. What will be the cell potential at a pH of 2.00 when the concentrations of Ni^{2+} and Ag^+ are each 0.030 *M*?

20.73 The $E^\circ_{cell} = 0.135$ V for the reaction

$$3I_2(s) + 5Cr_2O_7{}^{2-}(aq) + 34H^+ \longrightarrow 6IO_3{}^-(aq) + 10Cr^{3+}(aq) + 17H_2O$$

What is E_{cell} if $[Cr_2O_7{}^{2-}] = 0.010\ M$, $[H^+] = 0.10\ M$, $[IO_3{}^-] = 0.00010\ M$, and $[Cr^{3+}] = 0.0010\ M$?

OH ***20.74** A cell was set up having the following reaction.

$$Mg(s) + Cd^{2+}(aq) \longrightarrow Mg^{2+}(aq) + Cd(s) \qquad E^\circ_{cell} = 1.97 \text{ V}$$

The magnesium electrode was dipped into a 1.00 *M* solution of $MgSO_4$ and the cadmium electrode was dipped into a solution of unknown Cd^{2+} concentration. The potential of the cell was measured to be 1.54 V. What was the unknown Cd^{2+} concentration?

***20.75** A silver wire coated with AgCl is sensitive to the presence of chloride ion because of the half-cell reaction

$$AgCl(s) + e^- \rightleftharpoons Ag(s) + Cl^- \qquad E^\circ_{AgCl} = 0.2223 \text{ V}$$

A student, wishing to measure the chloride ion concentration in a number of water samples, constructed a galvanic cell using the AgCl electrode as one half-cell and a copper wire dipping into 1.00 *M* $CuSO_4$ solution as the other half-cell. In one analysis, the potential of the cell was measured to be 0.0895 V with the copper half-cell serving as the cathode. What was the chloride ion concentration in the water? (Take $E^\circ_{Cu^{2+}} = 0.3419$ V.)

***20.76** At 25 °C, a galvanic cell was set up having the following half-reactions.

$$Fe^{2+}(aq) + 2e^- \rightleftharpoons Fe(s) \qquad E^\circ_{Fe^{2+}} = -0.447 \text{ V}$$
$$Cu^{2+}(aq) + 2e^- \rightleftharpoons Cu(s) \qquad E^\circ_{Cu^{2+}} = +0.3419 \text{ V}$$

The copper half-cell contained 100 mL of 1.00 *M* $CuSO_4$. The iron half-cell contained 50.0 mL of 0.100 *M* $FeSO_4$. To the iron half-cell was added 50.0 mL of 0.500 *M* NaOH solution. The mixture was stirred and the cell potential was measured to be 1.175 V. Calculate the concentration of Fe^{2+} in the solution.

***20.77** Suppose a galvanic cell was constructed at 25 °C using a Cu/Cu^{2+} half-cell (in which the molar concentration of Cu^{2+} was 1.00 *M*) and a hydrogen electrode having a partial pressure of H_2 equal to 1 atm. The hydrogen electrode dips into a solution of unknown hydrogen ion concentration, and the two half-cells are connected by a salt bridge. The precise value of $E^\circ_{Cu^{2+}}$ is +0.3419 V.

(a) Derive an equation for the pH of the solution with the unknown hydrogen ion concentration, expressed in terms of E_{cell} and E°_{cell}.

(b) If the pH of the solution were 5.15, what would be the observed potential of the cell?

(c) If the potential of the cell were 0.645 V, what would be the pH of the solution?

***20.78** What is the potential of a concentration cell at 25.0 °C if it consists of silver electrodes dipping into two different solutions of $AgNO_3$, one with a concentration of 0.015 *M* and the other with a concentration of 0.50 *M*? What would be the potential of the cell if the temperature of the cell were 75 °C?

***20.79** What is the potential of a concentration cell at 25.0 °C if it consists of copper electrodes dipping into two different solutions of $Cu(NO_3)_2$, one with a concentration of 0.015 *M* and the other with a concentration of 0.50 *M*? What would be the potential of the cell if the temperature of the cell were 75 °C?

Quantitative Aspects of Electrochemical Reactions

20.80 How many moles of electrons are required to: **(a)** Reduce 0.20 mol Fe^{2+} to Fe? **(b)** Oxidize 0.70 mol Cl^- to Cl_2? **(c)** Reduce 1.50 mol Cr^{3+} to Cr? **(d)** Oxidize 1.0×10^{-2} mol Mn^{2+} to $MnO_4{}^-$?

20.81 How many moles of electrons are required to: **(a)** Produce 5.00 g Mg from molten $MgCl_2$? **(b)** Form 41.0 g Cu from a $CuSO_4$ solution?

ILW **20.82** How many grams of $Fe(OH)_2$ are produced at an iron anode when a basic solution undergoes electrolysis at a current of 8.00 A for 12.0 min?

20.83 How many grams of Cl_2 would be produced in the electrolysis of molten NaCl by a current of 4.25 A for 35.0 min?

ILW **20.84** How many hours would it take to produce 75.0 g of metallic chromium by the electrolytic reduction of Cr^{3+} with a current of 2.25 A?

20.85 How many hours would it take to generate 35.0 g of lead from $PbSO_4$ during the charging of a lead storage battery using a current of 1.50 A? The half-reaction is

$$Pb + HSO_4{}^- \longrightarrow PbSO_4 + H^+ + 2e^-$$

OH **20.86** How many amperes would be needed to produce 60.0 g of magnesium during the electrolysis of molten $MgCl_2$ in 2.00 hr?

20.87 A large electrolysis cell that produces metallic aluminum from Al_2O_3 by the Hall–Héroult process is capable of yielding 900 lb (409 kg) of aluminum in 24 hr. What current is required?

*20.88 The electrolysis of 250 mL of a brine solution (NaCl) was carried out for a period of 20.00 min with a current of 2.00 A in an apparatus that prevented Cl_2 from reacting with other products of the electrolysis. What is the concentration of hydroxide ions in the solution?

*20.89 A 100.0 mL sample of 2.00 *M* NaCl was electrolyzed for a period of 25.0 min with a current of 1.45 amperes, with stirring. What is the concentration of sodium hypochlorite produced?

Predicting Electrolysis Reactions

20.90 If electrolysis is carried out on an aqueous solution of aluminum sulfate, what products are expected at the electrodes? Write the equation for the net cell reaction.

20.91 If electrolysis is carried out on an aqueous solution of cadmium iodide, what products are expected at the electrodes? Write the equation for the net cell reaction.

OH 20.92 What products would we expect at the electrodes if a solution containing both KBr and $CuSO_4$ were electrolyzed? Write the equation for the net cell reaction.

20.93 What products would we expect at the electrodes if a solution containing both $BaCl_2$ and CuI_2 were electrolyzed? Write the equation for the net cell reaction.

20.94 Using Table 20.1, list the ions in aqueous solution that we would not expect to be reduced at the cathode.

20.95 Using Table 20.1, list the ions, in aqueous solution, that we would not expect to be oxidized at the anode.

Additional Exercises

*20.96 A watt is a unit of electrical power and is equal to one joule per second ($1 \text{ watt} = 1 \text{ J s}^{-1}$). How many hours can a calculator drawing 2.0×10^{-3} watt be operated by a mercury battery having a cell potential equal to 1.34 V if a mass of 1.00 g of HgO is available at the cathode? The cell reaction is

$$\text{HgO}(s) + \text{Zn}(s) \longrightarrow \text{ZnO}(s) + \text{Hg}(l)$$

*20.97 Suppose that a galvanic cell were set up having the net cell reaction

$$\text{Zn}(s) + 2\text{Ag}^+(aq) \longrightarrow \text{Zn}^{2+}(aq) + 2\text{Ag}(s)$$

The Ag^+ and Zn^{2+} concentrations in their respective half-cells initially are 1.00 *M*, and each half-cell contains 100 mL of electrolyte solution. If this cell delivers current at a constant rate of 0.10 A, what will the cell potential be after 15.00 hr?

*20.98 The value of K_{sp} for AgBr is 5.4×10^{-13}. What will be the potential of a cell constructed of a standard hydrogen electrode as one half-cell and a silver wire coated with AgBr dipping into 0.10 *M* HBr as the other half-cell. For the Ag/AgBr electrode,

$$\text{AgBr}(s) + e^- \rightleftharpoons \text{Ag}(s) + \text{Br}^-(aq) \qquad E^\circ_{\text{AgBr}} = +0.070 \text{ V}$$

*20.99 A student set up an electrolysis apparatus and passed a current of 1.22 A through a 3 *M* H_2SO_4 solution for 30.0 min. The H_2 formed at the cathode was collected and found to have a volume, over water at 27 °C, of 288 mL at a total pressure of 767 torr. Use these data to calculate the charge on the electron, expressed in coulombs.

*20.100 A hydrogen electrode is immersed in a 0.10 *M* solution of acetic acid at 25 °C. This electrode is connected to another consisting of an iron nail dipping into 0.10 *M* $FeCl_2$. What will be the measured potential of this cell? Assume $P_{H_2} = 1.00$ atm.

*20.101 What current would be required to deposit 1.00 m^2 of chrome plate having a thickness of 0.050 mm in 4.50 hr from a solution of H_2CrO_4? The density of chromium is 7.19 g cm^{-3}.

*20.102 A solution containing vanadium (chemical symbol V) in an unknown oxidation state was electrolyzed with a current of 1.50 A for 30.0 min. It was found that 0.475 g of V was deposited on the cathode. What was the original oxidation state of the vanadium ion?

*20.103 Consider the reduction potentials of the following sets of substances: **(a)** F_2, Cl_2, Br_2, and I_2 **(b)** Li^+, Na^+, K^+, Rb^-, and Cs^+ **(c)** Mg^{2+}, Ca^{2+}, Sr^{2+}, and Ba^{2+}. How do the reduction potentials correlate with properties such as electron affinities, ionization energies, and electronegativities? If necessary, suggest why a correlation does not occur.

*20.104 An Ag/AgCl electrode dipping into 1.00 *M* HCl has a standard reduction potential of +0.2223 V. The half-reaction is

$$\text{AgCl}(s) + e^- \rightleftharpoons \text{Ag}(s) + \text{Cl}^-(aq)$$

A second Ag/AgCl electrode is dipped into a solution containing Cl^- at an unknown concentration. The cell generates a potential of 0.0478 V, with the electrode in the solution of unknown concentration having a negative charge. What is the molar concentration of Cl^- in the unknown solution?

20.105 Consider the following galvanic cell:

$$\text{Ag}(s) \,|\, \text{Ag}^+(3.0 \times 10^{-4}\ M) \,\|\, \text{Fe}^{3+}(1.1 \times 10^{-3}\ M),\ \text{Fe}^{2+}(0.040\ M) \,|\, \text{Pt}(s)$$

Calculate the cell potential. Determine the sign of the electrodes in the cell. Write the equation for the spontaneous cell reaction.

Multi-Concept Problems

***20.106** The electrolysis of 0.250 L of a brine solution (NaCl) was carried out for a period of 20.00 min with a current of 2.00 A in an apparatus that prevented Cl_2 from reacting with other products of the electrolysis. The resulting solution was titrated with 0.620 *M* HCl. How many mL of the HCl solution was required for the titration?

OH ***20.107** A solution of NaCl in water was electrolyzed with a current of 2.50 A for 15.0 min. How many milliliters of dry Cl_2 gas would be formed if it was collected over water at 25 °C and a total pressure of 750 torr?

***20.108** How many milliliters of dry gaseous H_2, measured at 20.0 °C and 735 torr, would be produced at the cathode in the electrolysis of dilute H_2SO_4 with a current of 0.750 A for 15.00 min?

***20.109** At 25 °C, a galvanic cell was set up having the following half-reactions.

$$\mathrm{Fe}^{2+}(aq) + 2e^- \rightleftharpoons \mathrm{Fe}(s) \qquad E^\circ_{\mathrm{Fe}^{2+}} = -0.447\ \mathrm{V}$$
$$\mathrm{Cu}^{2+}(aq) + 2e^- \rightleftharpoons \mathrm{Cu}(s) \qquad E^\circ_{\mathrm{Cu}^{2+}} = +0.3419\ \mathrm{V}$$

The copper half-cell contained 100 mL of 1.00 *M* $CuSO_4$. The iron half-cell contained 50.0 mL of 0.100 *M* $FeSO_4$. To the iron half-cell was added 50.0 mL of 0.500 *M* NaOH solution. The mixture was stirred and the cell potential was measured to be 1.175 V. Calculate the value of K_{sp} for $Fe(OH)_2$.

***20.110** Given the following reduction half-reactions and their standard potentials, what is the molar solubility of silver bromide?

$$\mathrm{Ag}^+ + \mathrm{e}^- \longrightarrow \mathrm{Ag} \qquad E^\circ_{\mathrm{Ag}^+} = +0.80\ \mathrm{V}$$
$$\mathrm{AgBr} + \mathrm{e}^- \longrightarrow \mathrm{Ag} + \mathrm{Br}^- \qquad E^\circ_{\mathrm{AgBr}} = +0.07\ \mathrm{V}$$

***20.111** The normal range of chloride ions in blood serum (serum is the fluid left after the red blood cells clot) ranges from 0.096 to 0.106 *M*. An electrolysis apparatus can be set up to generate silver ions from a silver anode to precipitate the chloride ions. If the current used in the experiment is 0.500 ampere and if 3.00 mL of serum is transferred to the electrolysis cell, what range of time, in seconds, will a normal sample take to precipitate all of the chloride ions?

***20.112** An unstirred solution of 2.00 *M* NaCl was electrolyzed for a period of 25.0 min and then titrated with 0.250 *M* HCl. The titration required 15.5 mL of the acid. What was the average current in amperes during the electrolysis?

20.113 What masses of H_2 and O_2 in grams would have to react each second in a fuel cell at 110 °C to provide 1.00 kilowatt (kW) of power if we assume a thermodynamic efficiency of 70%? (*Hint*: Use data in Chapters 6 and 18 to compute the value of ΔG° for the reaction $H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(g)$ at 110 °C. 1 watt = 1 J s^{-1}.)

Exercises in Critical Thinking

20.114 In biochemical systems, the normal standard state that requires $[H^+] = 1.00\ M$ is not realistic. **(a)** Which half-reactions in Table 20.1 will have different potentials if pH = 7.00 is defined as the standard state for hydronium ions? **(b)** What will the new standard reduction potentials be at pH = 7.00 for these reactions? These are called $E^{\circ\prime}_{\mathrm{cell}}$ with the prime indicating the potential at pH = 7.00.

20.115 Calculate a new version of Table 20.1 using the lithium half-reaction to define zero. Does this change the results of any problems involving standard cell potentials?

20.116 In Problem 20.79, the potential at 75 °C was calculated. Does the change in molarity of the solutions, due to the change in density of water, have an effect on the potentials?

20.117 There are a variety of methods available for generating electricity. List as many methods as you can. Rank each of these methods based on your knowledge of **(a)** the efficiency of the method and **(b)** the environmental pollution caused by each method.

20.118 Using the cost of electricity in your area, how much will it cost to produce a case of 24 soda cans, each weighing 0.45 ounce? Assume that alternating current can be converted to direct current with 100% efficiency.

***20.119** Most flashlights use two or more batteries in series. Use the concepts of galvanic cells in this chapter to explain why a flashlight with two new batteries and one "dead" battery will give only a dim light if any light is obtained at all.

***20.120** If two electrolytic cells are placed in series, the same number of electrons must pass through both cells. One student argues you can get twice as much product if two cells are placed in series compared to a single cell and therefore the cost of production (i.e., the cost of electricity) will decrease greatly and profits will increase. Is the student correct? Explain your reasoning based on the principles of electrochemistry.

Chapters 17–20

Bringing It Together

Again we pause to provide you with an opportunity to see how well you have grasped concepts, how familiar you are with important terms, and how able you are at working chemistry problems. Keep in mind that many of the problems require tools developed in more than one chapter, including tools from Chapters 1–16. As you proceed, we encourage you to follow the approach taken by the worked examples you've studied.

1. At 60 °C, $K_w = 9.5 \times 10^{-14}$. What is the pH of pure water at this temperature? Why can we say that this water is neither acidic nor basic?

2. At 25 °C, the water in a natural pool of water in one of the western states was found to contain hydroxide ions at a concentration of 4.7×10^{-7} g OH^- per liter. Calculate the pH of this water and state if it is acidic, basic, or neutral.

3. The first antiseptic to be used in surgical operating rooms was phenol, C_6H_5OH, a weak acid and a potent bactericide. A 0.550 *M* solution of phenol in water was found to have a pH of 5.07.

(a) Write the chemical equation for the equilibrium involving C_6H_5OH in the solution.

(b) Write the equilibrium law corresponding to K_a for C_6H_5OH.

(c) Calculate the values of K_a and pK_a for phenol.

(d) Calculate the values of K_b and pK_b for the phenoxide ion, $C_6H_5O^-$.

4. The pK_a of saccharin, $HC_7H_5SO_3$, a sweetening agent, is 11.68.

(a) What is the pK_b of the saccharinate ion, $C_7H_5SO_3^-$?

(b) Does a solution of sodium saccharinate in water have a pH of 7, or is the solution acidic or basic? If the pH is not 7, calculate the pH of a 0.010 *M* solution of sodium saccharinate in water.

5. At 25 °C the value of K_b for codeine, a pain-killing drug, is 1.63×10^{-6}. Calculate the pH of a 0.0115 *M* solution of codeine in water.

6. Methylamine, CH_3NH_2, is a weak base. Write the chemical equation for the equilibrium that occurs in an aqueous solution of this solute. Write the equilibrium law corresponding to K_b for CH_3NH_2.

7. The pK_b of methylamine, CH_3NH_2, is 3.36. Calculate the pK_a of its conjugate acid, $CH_3NH_3^+$.

8. Ascorbic acid, $H_2C_6H_6O_6$, is a diprotic acid usually known as vitamin C. For this acid, pK_{a_1} is 4.10 and pK_{a_2} is 11.80. When 125 mL of a solution of ascorbic acid was evaporated to dryness, the residue of pure ascorbic acid had a mass of 3.12 g.

(a) Calculate the molar concentration of ascorbic acid in the solution before it was evaporated.

(b) Calculate the pH of the solution and the molar concentration of the ascorbate ion, $C_6H_6O_6^{2-}$, before the solution was evaporated.

9. What ratio of molar concentrations of sodium acetate to acetic acid can buffer a solution at a pH of 4.50?

10. Write a chemical equation for the reaction that would occur in a buffer composed of $NaC_2H_3O_2$ and $HC_2H_3O_2$ if

(a) some HCl were added.

(b) some NaOH were added.

11. If 0.020 mol of NaOH were added to 500 mL of a sodium acetate–acetic acid buffer that contains 0.10 *M* $NaC_2H_3O_2$ and 0.15 *M* $HC_2H_3O_2$, by how many pH units will the pH of the buffer change?

12. A biology experiment requires the use of a nutrient fluid buffered at a pH of 4.85, and 625 mL of this solution is needed. It has to be buffered to be able to hold the pH to within ±0.10 pH unit of 5.00 even if 5.00×10^{-3} mol of OH^- or 5.00×10^{-3} mol of H^+ ion enter.

(a) Using tabulated data, pick the best acid and its sodium salt that could be used to prepare this solution.

(b) Calculate the minimum number of grams of the pure acid and its salt that are needed to prepare this buffer solution.

(c) What are the molar concentrations of the acid and of its salt in this solution?

13. Would each of the following aqueous solutions test acidic, basic, or neutral? (Assume that each is at least 0.2 *M*.) (a) KNO_3, (b) $CrCl_3$, (c) NH_4I, (d) K_2HPO_4

14. When 50.00 mL of an acid with a concentration of 0.115 *M* (for which $pK_a = 4.87$) is titrated with 0.100 *M* NaOH, what is the pH at the equivalence point? What would be a good indicator for this titration?

15. Calculate the pH of a 0.050 *M* solution of sodium ascorbate, $NaC_6H_6O_6$. For ascorbic acid, $H_2C_6H_6O_6$, $K_{a_1} = 8.0 \times 10^{-5}$ and $K_{a_2} = 1.6 \times 10^{-12}$.

16. When 25.0 mL of 0.100 *M* NaOH was added to 50.0 mL of a 0.100 *M* solution of a weak acid, HX, the pH of the mixture reached a value of 3.56. What is the value of K_a for the weak acid?

17. How many grams of solid NaOH would have to be added to 100 mL of a 0.100 *M* solution of NH_4Cl to give a mixture with a pH of 9.26?

18. The molar solubility of silver chromate, Ag_2CrO_4, in water is 6.5×10^{-5} *M*. What is K_{sp} for Ag_2CrO_4?

19. What is the pH of a saturated solution of $Mg(OH)_2$?

20. What is the solubility of $Fe(OH)_2$ in grams per liter if the solution is buffered to a pH of 10.00?

21. Which of the following states has the greatest entropy?

(a) $2H_2O(l)$, (c) $2H_2(l) + O_2(g)$,

(b) $2H_2O(s)$, (d) $2H_2(g) + O_2(g)$,

(e) $4H(g) + 2O(g)$

22. Suppose 30.0 mL of a solution containing 1.040 g $Pb(NO_3)_2$ is added to 20.0 mL of 0.500 *M* KI.

(a) How many grams of PbI_2 will be formed?

(b) What will the molar concentrations of all the ions be in the mixture after equilibrium has been reached?

(c) If a lead electrode is immersed in the mixture and the resulting half-cell is connected to another half-cell composed of a copper electrode dipping into 1.00 *M* $CuSO_4$, what will be the potential of the cell?

23. How many moles of NH_3 must be added to 1.00 L of solution to dissolve 1.00 g of $CuCO_3$? For $CuCO_3$, $K_{sp} = 2.5 \times 10^{-10}$. Ignore hydrolysis of CO_3^{2-}, but consider the formation of the complex ion, $Cu(NH_3)_4^{2+}$.

24. Over what pH range must a solution be buffered to achieve a selective separation of the carbonates of barium, $BaCO_3$, ($K_{sp} = 2.6 \times 10^{-9}$), and lead, $PbCO_3$ ($K_{sp} = 7.4 \times 10^{-14}$)? The solution is initially 0.010 *M* in Ba^{2+} and 0.010 *M* in Pb^{2+}.

25. A solution containing 0.10 *M* Pb^{2+} and 0.10 *M* Ni^{2+} is to be saturated with H_2S. What range of pH values could this solution have so that when the procedure is completed one of the ions remains in solution while the other is precipitated as its sulfide?

26. A solution that contains 0.10 *M* Fe^{2+} and 0.10 *M* Sn^{2+} is maintained at a pH of 3.00 while H_2S is gradually added to it. What will be the concentration of Sn^{2+} in the solution when FeS just begins to precipitate?

27. A metal sulfide *M*S has a value of K_{sp} of 4.0×10^{-29}. (a) What is the value of K_{spa} for this compound? (b) Calculate the molar solubility of *M*S in 0.30 *M* HCl. (c) Does *M*S fall into cation group 2 or cation group 3?

28. Use thermodynamic data and other information available in previous chapters to calculate K_c at 200 °C for the reaction

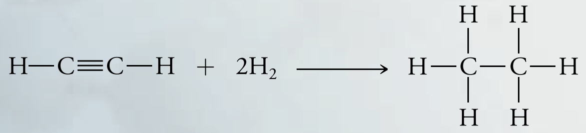
$$3NO(g) \rightleftharpoons NO_2(g) + N_2O(g)$$

29. Suppose 4.56 g of CH_4 and 8.67 g of HCl were placed in a 2.00 L container at 200 °C where the following equilibrium is established.

$$CH_4(g) + Cl_2(g) \rightleftharpoons CH_3Cl(g) + HCl(g)$$

Use thermodynamic data and other information available in this book to calculate the concentrations of all the gases at equilibrium.

30. Use bond energies to calculate the approximate energy that would be absorbed or given off in the formation of 25.0 g of C_2H_6 by the following reaction in the gas phase.



$$H{-}C{\equiv}C{-}H + 2H_2 \longrightarrow H{-}\overset{\displaystyle H}{\underset{\displaystyle H}{C}}{-}\overset{\displaystyle H}{\underset{\displaystyle H}{C}}{-}H$$

31. Consider an electrolytic cell in which 250 mL of a concentrated solution of NaCl is undergoing electrolysis.

(a) What will be the pH of the solution if the electrolysis is carried out for 20.0 minutes using a current of 1.00 A?

(b) How many milliliters of H_2, measured at STP, would be evolved if the cell were operated at 5.00 A for 10.0 minutes?

32. Sketch a diagram of a galvanic cell consisting of a copper electrode dipping into 1.00 *M* $CuSO_4$ solution and an iron electrode dipping into 1.00 *M* $FeSO_4$ solution.

(a) Identify the cathode and the anode. Indicate the charge carried by each.

(b) Write the equation for the net cell reaction.

(c) Describe the cell by writing its standard cell notation.

(d) What is the potential of the cell?

(e) If the cell contains 100 mL of each solution and is operated for a period of 50.0 hr at a constant current of 0.10 A, what will be the cell potential at this point?

33. A galvanic cell was constructed in which one half-cell consists of a silver electrode coated with silver chloride dipping into a solution that contains 0.050 *M* Cl^- and the second half-cell consists of a nickel electrode dipping into a solution buffered to a pH of 12.00 that contains insoluble $Ni(OH)_2$. The half-cell reactions and their reduction potentials are

$$AgCl(s) + e^- \rightleftharpoons Ag(s) + Cl^-(aq) \qquad E° = +0.222\ V$$

$$Ni^{2+}(aq) + 2e^- \rightleftharpoons Ni(s) \qquad E° = -0.257\ V$$

(a) Write the equation for the spontaneous cell reaction.

(b) Calculate E_{cell} for the galvanic cell described above.

34. Suppose a galvanic cell was established using the following cell reaction,

$$Cu(s) + 2Ag^+(0.100\ M) \longrightarrow Cu^{2+}(0.200\ M) + 2Ag(s)$$

What is the potential of the cell at 25 °C? How long would it take at a constant current of 0.10 A for the potential to drop by 10%? By how many grams will the total mass of the two electrodes change during this time period? Will the entire mass of the galvanic cell change?

21 Nuclear Reactions and Their Role in Chemistry

Chapter Outline

21.1 | Conservation of Mass and Energy

21.2 | Nuclear Binding Energy

21.3 | Radioactivity

21.4 | Band of Stability

21.5 | Transmutation

21.6 | Measuring Radioactivity

21.7 | Medical and Analytical Applications of Radionuclides

21.8 | Nuclear Fission and Fusion

What is the Asian brown cloud? This large brown cloud of pollution hangs over southeast Asia from January to March. While atmospheric chemists know it is formed from particulates created when fuels are not completely burned, they are also interested in the source of the fuels. By using the nuclear reactions of the elements of the Asian brown cloud, these scientists are able to determine the age of the material that was burned to form the cloud. Johannes Mann/©Corbis

This Chapter in Context

From the standpoint of chemistry, our interest in the atomic nucleus stems primarily from its role in determining the number and energies of an atom's electrons. This is because it is the electron distribution in an atom that controls chemical properties. Although the nuclei of most isotopes are exceptionally stable, many of the elements also have one or more isotopes with unstable nuclei that have unique properties which make them particularly useful and interesting. These unstable nuclei are able to undergo *nuclear reactions*, and tend to emit radiation consisting of particles and/or energy. In the pages ahead you will learn about the different kinds of nuclear radiation, how this radiation is detected and measured, and how the properties of unstable nuclei can be applied to practical problems.

One of the benefits of studying nuclear transformations is an understanding of the enormous amounts of energy associated with certain nuclear changes. As you study this chapter you will come to appreciate the origin of the energy given off by stars, including our own sun. You will also learn how nuclear reactors work and how nuclear reactions have been applied to produce nuclear weapons.

21.1 | Conservation of Mass and Energy

Changes involving unstable atomic nuclei generally involve large amounts of energy, amounts that are considerably greater than in chemical reactions. To understand how these energy changes arise, we begin our study by reexamining two physical laws that, until this chapter, have been assumed to be separate and independent—namely, the laws of conservation of energy and conservation of mass. They may be safely treated as distinct for chemical reactions but not for nuclear reactions. These two laws, however, are only different aspects of a deeper, more general law.

As atomic and nuclear physics developed in the early 1900s, physicists realized that the mass of a particle cannot be treated as a constant in all circumstances. The mass, m, of a particle depends on the particle's velocity, v, relative to the observer. A particle's mass is related to this velocity, and to the velocity of light, c, by Equation 21.1.

$$m = \frac{m_0}{\sqrt{1 - (v/c)^2}} \tag{21.1}$$

■ $c = 2.99792458 \times 10^8$ m s^{-1}, the speed of light.

Notice what happens when v is zero and the particle has no velocity relative to the observer. The ratio v/c is then zero, the entire denominator reduces to a value of 1, and Equation 21.1 becomes

$$m = m_0$$

Thus the symbol m_0 stands for the particle's *rest mass*.

Rest mass is what we measure in all lab operations, because any object, like a chemical sample, is either at rest (from our viewpoint) or is not moving extraordinarily rapidly. Only as the particle's velocity approaches the speed of light, c, does the v/c term in Equation 21.1 become important. As v approaches c, the ratio v/c approaches 1, and so $[1 - (v/c)^2]$ gets closer and closer to 0. The whole denominator, in other words, approaches a value of 0. If it actually reached 0, then m, which would be $(m_0 \div 0)$, would become infinity. In other words, the mass, m, of the particle moving at the velocity of light would be infinitely great, a physical impossibility. Thus the speed of light is seen as the absolute upper limit of the speed that any particle can approach.

■ Even at $v = 1000$ m s^{-1} (about 2250 mph), the denominator (not rounded) is 0.99999333, or within 7×10^{-4}% of 1.

At the velocities of everyday experience, the mass of anything calculated by Equation 21.1 equals the rest mass to four or five significant figures. The difference cannot be detected by weighing devices. Thus, in all of our normal work, mass appears to be conserved, and the law of conservation of mass functions this way in chemistry.

Practice Exercises

21.1 | What is the mass of a golf ball traveling at 75 m s^{-1}? The rest mass of a golf ball is 45.9 g, as regulated by the United States Golf Association. (*Hint*: How does the velocity of the golf ball affect the speed?)

21.2 | What is the mass of the same golf ball in Practice Exercise 21.1 if the velocity of the ball is increased to 7.5×10^6 m s^{-1}?

Law of Conservation of Mass–Energy

We know that matter cannot appear from nothing, so the extra mass an object acquires as it goes faster must come from the energy supplied to increase the object's velocity. Physicists, therefore, realized that mass and energy are interconvertible and that in the world of high-energy physics, the laws of conservation of mass and conservation of energy are not separate and independent. What emerged was a single law now called the **law of conservation of mass–energy**.

> **Law of Conservation of Mass–Energy**
> The sum of all of the energy in the universe and of all of the mass (expressed as an equivalent in energy) is a constant.

The Einstein Equation

The Einstein equation is given as $E = mc^2$ in the popular press.

TOOLS Einstein equation

Albert Einstein was able to show that when mass converts to energy, the change in energy, ΔE, is related to the change in rest mass, Δm_0, by the following equation, now called the **Einstein equation:**

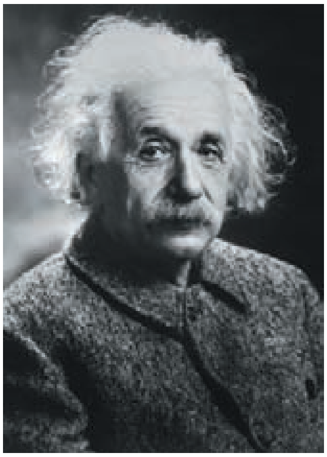
$$\Delta E = \Delta m_0 c^2 \tag{21.2}$$

Again, c is the velocity of light, 3.00×10^8 m s^{-1}.

Because the velocity of light is very large, even if an energy change is enormous, the change in mass, Δm_0, is extremely small. For example, the combustion of methane releases considerable heat per mole:

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l) \qquad \Delta H° = -890 \text{ kJ}$$

The release of 890 kJ of heat energy corresponds to a loss of mass, which by the Einstein equation equals a loss of 9.89 ng. This is about 1×10^{-7}% of the total mass of 1 mol of CH_4 and 2 mol of O_2. Such a tiny change in mass is not detectable by laboratory balances, so for all practical purposes, mass is conserved. Although the Einstein equation has no direct applications in chemistry involving the rearrangement of electrons in chemical reactions, its importance became clear when atomic fission (i.e., the breaking apart of heavy atoms to form lighter fragments) was first observed in 1939.



Albert Einstein (1879–1955); Nobel Prize, 1921 (physics) *(Photo Researchers)*

21.2 | Nuclear Binding Energy

As we will discuss further in Section 21.3, an atomic nucleus is held together by extremely powerful forces of attraction that are able to overcome the repulsions between protons. To break a nucleus into its individual **nucleons**—that is, protons and neutrons—therefore requires an enormous input of energy. This energy is called the **nuclear binding energy.**

Absorption of the binding energy would produce the individual nucleons that had made up the nucleus. These nucleons would now carry extra mass corresponding to the mass-equivalent of the energy they had absorbed. If we add up their masses, the sum should be larger than the mass of the nucleus from which they had come. And this is exactly what is observed. *For a given atomic nucleus, the sum of the rest masses of all of its nucleons is always a little larger than the actual mass of the nucleus.* The mass difference is called the **mass defect**, and its energy equivalance is the nuclear binding energy.

Keep in mind that nuclear binding energy is not energy actually possessed by the nucleus but is, instead, the energy the nucleus would have to absorb to break apart. Thus, the *higher* the binding energy, the *more stable* is the nucleus.

Calculating Nuclear Binding Energies

We can calculate nuclear binding energy with the Einstein equation, using helium-4 as an example. The rest mass of an isolated proton is 1.0072764669 u and that of a neutron is 1.0086649156 u. Helium-4 has atomic number 2, so its nucleus consists of four nucleons (two protons and two neutrons). The rest mass of one helium-4 nucleus is known to be 4.0015061792 u. However, the sum of the rest masses of its four separated nucleons is slightly more, 4.0318827650 u, which we can show as follows:

$$\begin{aligned}\text{For 2 protons: } 2 \times 1.0072764669\text{ u} &= 2.0145529338\text{ u}\\ \text{For 2 neutrons: } 2 \times 1.0086649156\text{ u} &= \underline{2.0173298312\text{ u}}\\ \text{Total rest mass of nucleons in } {}^{4}\text{He} &= 4.0318827650\text{ u}\end{aligned}$$

The mass defect, the difference between the calculated and measured rest masses for the helium-4 nucleus, is 0.030375858 u:

$$\underset{\text{mass of the 4 nucleons}}{4.0318827650\text{ u}} - \underset{\text{mass of nucleus}}{4.0015061792\text{ u}} = \underset{\text{mass defect}}{0.030375858\text{ u}}$$

Using Einstein's equation, let's calculate to four significant figures the nuclear binding energy that is equivalent to the mass defect for the ^{4}He nucleus. We will round the mass defect to 0.03038 u. To obtain the energy in joules, we have to remember that 1 J = 1 kg m^{2} s^{-2}, so the mass in atomic mass units (u) must be converted to kilograms. The table of constants inside the rear cover of the book gives 1 u = $1.66053878 \times 10^{-24}$ g, which equals $1.66053878 \times 10^{-27}$ kg. Substituting into the Einstein equation gives

$$\begin{aligned}\Delta E = \Delta mc^{2} &= \underbrace{(0.03038\ \cancel{\text{u}}) \times \frac{1.660653878 \times 10^{-27}\text{ kg}}{1\ \cancel{\text{u}}}}_{\Delta m\text{ (in kg)}} \times \underbrace{(2.9979 \times 10^{8}\text{ m s}^{-1})^{2}}_{c^{2}}\\ &= 4.534 \times 10^{-12}\text{ kg m}^{2}\text{ s}^{-2}\\ &= 4.534 \times 10^{-12}\text{ J}\end{aligned}$$

There are four nucleons in the helium-4 nucleus, so the binding energy *per* nucleon is (4.534×10^{-12} J/4 nucleons) or 1.134×10^{-12} J/nucleon.

The formation of just one nucleus of ^{4}He releases 4.534×10^{-12} J, which is a very small amount of energy. If we could make Avogadro's number or 1 mol of ^{4}He nuclei (with a total mass of only 4 g), the net release of energy would be

$$(6.022 \times 10^{23}\text{ nuclei}) \times (4.534 \times 10^{-12}\text{ J/nucleus}) = 2.731 \times 10^{12}\text{ J}$$

This is a huge amount of energy from forming only 4 g of helium. It could keep a 100 watt incandescent light bulb lit for nearly 900 years!

Practice Exercises

21.3 | Calculate the mass defect for the neon-20 nucleus. The mass of neon-20 is 19.992440 u. (*Hint*: How many protons and neutrons does neon-20 have?)

21.4 | Calculate the binding energy per nucleon for the boron-10 nucleus, whose mass is 10.012937 u.

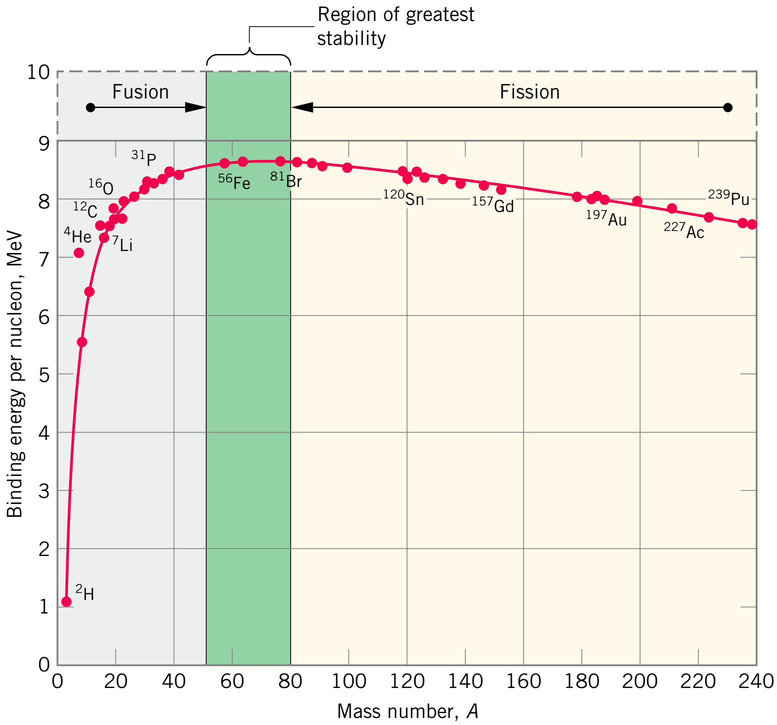


Figure 21.1 | **Binding energies per nucleon.** ES: Can we update this reference since it has been in more recent editions of the book. (*From D. Halliday, R. Resnick, and J. Walker,* Fundamentals of Physics, *9th ed., revised, 2011. John Wiley & Sons, Inc. Used by permission*).

Binding Energy and Nuclear Stability

Figure 21.1 shows a plot of binding energies per nucleon versus mass numbers for most of the elements. We are interested in this because the larger the binding energy per nucleon, the more stable the nucleus. The curve passes through a maximum at iron-56, which means that the iron-56 nuclei are the most stable of all. The plot in Figure 21.1, however, does not have a sharp maximum. Thus, a large number of elements with intermediate mass numbers in the broad center of the periodic table include the most stable isotopes in nature.

Nuclei of low mass number have small binding energies per nucleon. Joining two such nuclei to form a heavier nucleus, a process called **nuclear fusion**, leads to a more stable nucleus and a large increase in binding energy per nucleon. This extra energy is released when the two lighter nuclei fuse (join) and is the origin of the energy released in the cores of stars and the detonation of a hydrogen bomb. Nuclear fusion is discussed further in Section 21.8.

As we follow the plot of Figure 21.1 to the higher mass numbers, the nuclei decrease in stability as the binding energies decrease. Among the heaviest atoms, therefore, we might expect to find isotopes that could change to more stable forms by breaking up into lighter nuclei, by undergoing nuclear fission. **Nuclear fission**, the subject of Section 21.8, is the spontaneous breaking apart of a nucleus to form isotopes of intermediate mass number.

21.3 | Radioactivity

Except for hydrogen, all atomic nuclei have more than one proton, each of which carries a positive charge. Because like charges repel, we might wonder how any nucleus could be stable. However, the electrostatic forces of attraction and repulsion, such as the kinds present among the ions in a crystal of sodium chloride, are not the only forces at work in the nucleus. Protons do, indeed, repel each other electrostatically, but another force, a force of attraction called the *nuclear strong force,* also acts in the nucleus. The nuclear strong force, effective only at very short distances, overcomes the electrostatic force of repulsion between protons, and it binds both protons and neutrons into a nuclear package. Moreover, the neutrons, by helping to keep the protons farther apart, also lessen repulsions between protons.

■ Quite often you'll see the terms "atomic fusion" and "atomic fission" used for nuclear fusion and nuclear fission, respectively.

■ Adjacent neutrons experience no electrostatic repulsion between each other, only the attractive strong force.

One consequence of the difference between the nuclear strong force and the electrostatic force occurs among nuclei that have large numbers of protons but too few intermingled neutrons to dilute the electrostatic repulsions between protons. Such nuclei are often unstable because their nuclei carry excess energy. To achieve a lower energy and thus more stability, unstable nuclei have a tendency to eject small nuclear fragments, and many simultaneously release high-energy electromagnetic radiation. The stream of particles (or photons) coming from the sample is called **nuclear radiation** or **atomic radiation** and the phenomenon is called **radioactivity.** Isotopes that exhibit this property are called **radionuclides.** About 60 of the approximately 350 naturally occurring isotopes are radioactive.

In a sample of a given radionuclide, not all of the atoms undergo change at once. The rate at which radiation is emitted (which translates into the intensity of the radiation) depends on the identity of the isotope in the sample. Over time, as radioactive nuclei change into stable ones, the number of atoms of the radionuclide remaining in the sample decreases, causing the intensity of the radiation to drop, or *decay*. The radionuclide is said to undergo **radioactive decay.**

Naturally occurring atomic radiation consists principally of three kinds: alpha, beta, and gamma radiation, as discussed below. Other types of radiation also occur. They are summarized in Table 21.1 and are described on the pages ahead.

Alpha Radiation

Alpha radiation consists of a stream of helium nuclei called **alpha particles**, symbolized as ${}^{4}_{2}\text{He}$, where 4 is the mass number and 2 is the atomic number. The alpha particle bears a charge of 2+, but the charge is omitted from the symbol.

Alpha particles are the most massive of those commonly emitted by radionuclides. When ejected (Figure 21.2), alpha particles move through the atom's electron orbitals,

■ In Chapter 3 you learned that an isotope is identified by writing its mass number, *A*, as a superscript and its atomic number, *Z*, as a subscript in front of the chemical symbol, *X*, as in ${}^{A}_{Z}X$. We use this same notation in representing particles involved in nuclear reactions. For particles that are not atomic nuclei, *Z* stands for the charge on the particle.

Table 21.1 Nuclear Reactions

Type of Radioactivity	Particle	Symbol	Equation Example	Example
Alpha Radiation	${}^{4}_{2}\text{He}$	${}^{4}_{2}\alpha$	${}^{A}_{Z}X \rightarrow {}^{A-4}_{Z-2}Y + {}^{4}_{2}\text{He}$ ${}^{263}_{106}\text{Sg} \rightarrow {}^{259}_{104}\text{Rf} + {}^{4}_{2}\text{He}$	 Parent Nuclide Daughter Nuclide Alpha Particle +
Beta Radiation	${}^{0}_{-1}e$	${}^{0}_{-1}\beta$	${}^{A}_{Z}X \rightarrow {}^{A}_{Z+1}Y + {}^{0}_{-1}e$ ${}^{14}_{6}\text{C} \rightarrow {}^{14}_{7}\text{N} + {}^{0}_{-1}e$	 Parent Nuclide Daughter Nuclide + Neutron Proton Electron
Gamma Radiation	${}^{0}_{0}\gamma$	γ	${}^{A}_{Z}X^{*} \rightarrow {}^{A}_{Z}X + \gamma$ ${}^{60}_{28}\text{Ni}^{*} \rightarrow {}^{60}_{28}\text{Ni} + \gamma$	 * + γ Excited State Nucleus Ground State Nucleus
Positron Emission	${}^{0}_{1}e$	${}^{0}_{+1}\beta$	${}^{A}_{Z}X \rightarrow {}^{A}_{Z-1}Z + {}^{0}_{1}e$ ${}^{54}_{27}\text{Co} \rightarrow {}^{54}_{26}\text{Fe} + {}^{0}_{1}e$	 Parent Nuclide Daughter Nuclide Positron + Proton Proton became a neutron
Neutron Emission	${}^{1}_{0}n$	${}^{1}_{0}n$	${}^{A}_{Z}X \rightarrow {}^{A-1}_{Z}X + {}^{1}_{0}n$ ${}^{87}_{36}\text{Kr} \rightarrow {}^{86}_{36}\text{Kr} + {}^{1}_{0}n$	 Parent Nuclide Daughter Nuclide Neutron + Neutron to be lost
Electron Capture	${}^{0}_{-1}e$	${}^{0}_{-1}e$	${}^{A}_{Z}X + {}^{0}_{-1}e \rightarrow {}^{A}_{Z-1}Y$ ${}^{50}_{23}V + {}^{0}_{-1}e \rightarrow {}^{50}_{22}\text{Ti}$	 Parent Nuclide Electron Daughter Nuclide + Proton Neutron

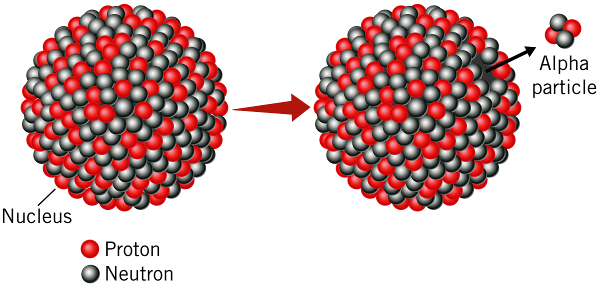

Figure 21.2 | **Emission of an alpha particle from an atomic nucleus.** Removal of ^4_2He from a nucleus decreases the atomic number by 2 and the mass number by 4.

emerging from the atom at speeds of up to one-tenth the speed of light. Their size, however, prevents them from going far. After traveling at most only a few centimeters in air, alpha particles collide with air molecules, lose kinetic energy, pick up electrons, and become neutral helium atoms. Alpha particles themselves cannot penetrate the skin, although enough exposure causes a severe skin burn. If carried in air or on food into the soft tissues of the lungs or the intestinal tract, emitters of alpha particles can cause serious harm, including cancer.

Nuclear Equations

■ A nuclear transformation such as the alpha decay of ^{238}U does not depend on the chemical environment. The same nuclear equation applies whether the uranium is in the form of the free element or in a compound.

To symbolize the decay of a nucleus, we construct a **nuclear equation**, which we can illustrate by the alpha decay of uranium-238 to thorium-234:

$$^{238}_{92}\text{U} \longrightarrow {}^{234}_{90}\text{Th} + {}^{4}_{2}\text{He}$$

Unlike chemical reactions, nuclear reactions produce new isotopes, so we need separate rules for balancing nuclear equations.

TOOLS

Balancing nuclear equations

Rules for balancing a nuclear equation:

1. *The sum of the mass numbers on each side of the arrow must be the same.*
2. *The sum of the atomic numbers (nuclear charge) on each side of the arrow must be the same.*

In the nuclear equation for the decay of uranium-238, the atomic numbers balance ($90 + 2 = 92$), and the mass numbers balance ($234 + 4 = 238$). Notice that electrical charges are not shown, even though they are there (initially). The alpha particle, for example, has a charge of 2+. If it was emitted by a neutral uranium atom, then the thorium particle initially has a charge of 2−. These charged particles, however, eventually pick up or lose electrons either from each other or from molecules in the matter through which they travel.

Beta Radiation

Naturally occurring **beta radiation** consists of a stream of electrons, which in this context are called **beta particles**. In a nuclear equation, the beta particle has the symbol $^{0}_{-1}e$, because the electron's mass number is 0 and its charge is 1−. Hydrogen-3 (tritium) is a beta emitter that decays by the following equation:

■ Sometimes the beta particle is given the symbol $^{0}_{-1}\beta$, or simply $\beta-$.

$$\underset{\text{tritium}}{^3_1\text{H}} \longrightarrow \underset{\text{helium-3}}{^3_2\text{He}} + \underset{\substack{\text{beta-particle}\\\text{(electron)}}}{^{0}_{-1}e} + \underset{\text{antineutrino}}{\overline{\nu}}$$

Both the antineutrino (to be described further shortly) and the beta particle come from the atom's nucleus, not its electron shells. We do not think of them as having a prior existence in the nucleus, any more than a photon exists before its emission from an excited

Figure 21.3 | **Emission of a beta particle from a tritium nucleus.** Emission of a beta particle changes a neutron into a proton. This results in a positively charged ion, which picks up an electron to become a neutral atom.

atom (see Figure 21.3). Both the beta particle and the antineutrino are created during the decay process in which a neutron is transformed into a proton:

$$\underset{\substack{\text{neutron}\\ \text{(in the}\\ \text{nucleus)}}}{{}^{1}_{0}n} \longrightarrow \underset{\substack{\text{beta particle}\\ \text{(emitted)}}}{{}^{0}_{-1}e} + \underset{\substack{\text{proton}\\ \text{(remains in}\\ \text{the nucleus)}}}{{}^{1}_{1}p} + \underset{\substack{\text{antineutrino}\\ \text{(emitted)}}}{\overline{\nu}}$$

Unlike alpha particles, which are all emitted with the same discrete energy from a given radionuclide, beta particles emerge from a given beta emitter with a continuous spectrum of energies. Their energies vary from zero to some characteristic fixed upper limit for each radionuclide. This fact once gave nuclear physicists considerable trouble, partly because it was an apparent violation of energy conservation. To solve this problem, Wolfgang Pauli proposed in 1927 that beta emission is accompanied by emission of yet another decay particle, this one electrically neutral and almost massless. Enrico Fermi suggested the name *neutrino* ("little neutral one"), but eventually it was named the *antineutrino*, symbolized by $\overline{\nu}$.

An electron is extremely small, so a beta particle is less likely to collide with any atoms or molecules in the medium through which it travels. Depending on its initial kinetic energy, a beta particle can travel up to 300 cm (about 10 ft) in dry air, much farther than alpha particles. However, only the highest energy beta particles can penetrate the skin.

Gamma Radiation

Gamma radiation, which often accompanies most nuclear decays, consists of high-energy photons given the symbol ${}^{0}_{0}\gamma$ or, often, simply γ in equations. Gamma radiation is extremely penetrating and is effectively blocked only by very dense materials, like lead.

■ Gamma photons have the symbol ${}^{0}_{0}\gamma$ because they have no charge or mass.

The emission of gamma radiation involves transitions between energy levels *within* the nucleus. Nuclei have energy levels of their own, much as atoms have orbital energy levels. When a nucleus emits an alpha or beta particle, it sometimes is left in an excited energy state. By the emission of a gamma-ray photon, the nucleus relaxes into a more stable state. For example, cobalt-60 emits a beta particle and forms a nickel-60 isotope in a nuclear excited state, which then emits two γ particles.

$${}^{60}_{27}\text{Co} \longrightarrow {}^{60}_{28}\text{Ni}^{*} + {}^{0}_{-1}e \longrightarrow {}^{60}_{28}\text{Ni} + 2\gamma$$

The excited state is indicated by an asterisk.

The Electron Volt

The energy carried by a given radiation is usually described by an energy unit new to our study, the **electron volt**, abbreviated **eV**; 1 eV is the energy an electron receives when accelerated under the influence of 1 volt. It is related to the joule as follows:

$$1\ \text{eV} = 1.602 \times 10^{-19}\ \text{J}$$

■ In the interconversion of mass and energy,

$$1 \text{ eV} \Leftrightarrow 1.783 \times 10^{-36} \text{ kg}$$
$$1 \text{ MeV} \Leftrightarrow 1.78 \times 10^{-27} \text{ g}$$
$$1 \text{ GeV} \Leftrightarrow 1.783 \times 10^{-24} \text{ g}$$

As you can see, the electron volt is an extremely small amount of energy, so multiples are commonly used, such as the kilo-, mega-, and gigaelectron volt.

$$1 \text{ keV} = 10^3 \text{ eV}$$
$$1 \text{ MeV} = 10^6 \text{ eV}$$
$$1 \text{ GeV} = 10^9 \text{ eV}$$

An alpha particle emitted by radium-224 has an energy of 5 MeV. Hydrogen-3 (tritium) emits beta radiation at an energy of 0.05 to 1 MeV. The gamma radiation from cobalt-60, the radiation currently used to kill bacteria and other pests in certain foods, consists of photons with energies of 1.173 MeV and 1.332 MeV.

Example 21.1
Writing a Balanced Nuclear Equation

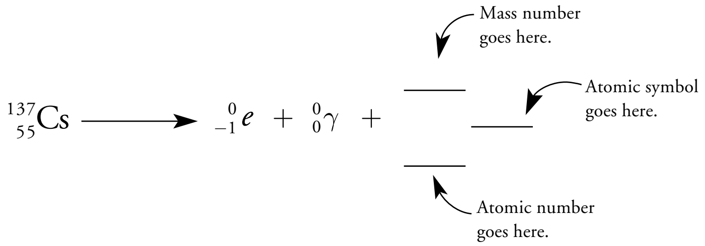
■ Ions of cesium, which is in the same family as sodium, travel in the body to many of the same sites where sodium ions go.

Cesium-137, ${}^{137}_{55}\text{Cs}$, one of the radioactive wastes from a nuclear power plant or an atomic bomb explosion, emits beta and gamma radiation. Write the nuclear equation for the decay of cesium-137.

■ Analysis: We are being asked to balance a nuclear equation, and when we do this, we need to keep track of the atomic numbers and the mass numbers.

■ Assembling the Tools: We will start with an incomplete equation using the given information. Then we will use the requirements for a balanced nuclear equation as a tool to figure out any other data needed to complete the equation. We also have to realize that a beta particle is an electron emitted from the nucleus as a neutron is converted into a proton and an electron, and its symbol is ${}^{0}_{-1}e$. Therefore, the atomic number will have to go up by one.

■ Solution: The incomplete nuclear equation is



Mass number goes here.
${}^{137}_{55}\text{Cs} \longrightarrow {}^{0}_{-1}e + {}^{0}_{0}\gamma +$
Atomic symbol goes here.
Atomic number goes here.

After we have determined the atomic number, Z, the atomic symbol can be obtained from the periodic table. Z is found using the fact that the atomic number (55) on the left side of the equation must equal the sum of the atomic numbers on the right side.

$$55 = -1 + 0 + Z$$
$$Z = 56$$

According to the periodic table, element 56 is Ba (barium). To determine which isotope of barium forms, we use the requirement that the sums of the mass numbers on either side of the equation must also be equal. Letting A be the mass number of the barium isotope,

$$137 = 0 + 0 + A$$
$$A = 137$$

The balanced nuclear equation, therefore, is

$${}^{137}_{55}\text{Cs} \longrightarrow {}^{0}_{-1}e + {}^{0}_{0}\gamma + {}^{137}_{56}\text{Ba}$$

■ **Is the Answer Reasonable?** Besides double-checking that element 56 is barium, the answer satisfies the requirements of a nuclear equation—namely, the sums of the mass numbers, 137, are the same on both sides, as are the sums of the atomic numbers.

Practice Exercises

21.5 | Marie Curie earned one of her two Nobel Prizes for isolating the element radium, which soon became widely used to treat cancer. Radium-226, ${}^{226}_{88}\text{Ra}$, emits a gamma photon plus an alpha particle to give radon-222. Write a balanced nuclear equation for its decay and identify the particle that's emitted. (*Hint*: Be sure to balance atomic numbers and mass numbers.)

21.6 | Write the balanced nuclear equation for the decay of strontium-90, a beta emitter. (Strontium-90 is one of the many radionuclides present in the wastes of operating nuclear power plants.)

Positron and Neutron Emission

Many *synthetic isotopes* (isotopes not found in nature, but synthesized by methods discussed in Section 21.5) emit *positrons*, which are particles with the mass of an electron but a positive instead of a negative charge. A **positron** is a positive beta particle, a positive electron, and its symbol is ${}^{0}_{1}e$. It forms in the nucleus by the conversion of a proton to a neutron (Figure 21.4). Positron emission, like beta emission, is accompanied by a chargeless and virtually massless particle, a *neutrino* (ν), the counterpart of the antineutrino ($\overline{\nu}$) in the realm of *antimatter* (defined below). Cobalt-54, for example, is a positron emitter and changes to a stable isotope of iron:

■ The symbol ${}^{+}\beta$ is sometimes used for the positron.

$$ {}^{54}_{27}\text{Co} \longrightarrow {}^{54}_{26}\text{Fe} + \underset{\text{positron}}{{}^{0}_{1}e} + \underset{\text{neutrino}}{\nu} $$

A positron, when emitted, eventually collides with an electron, and the two annihilate each other (Figure 21.5). Their masses change entirely into the energy of two gamma-ray photons called *annihilation radiation photons*, each with an energy of 511 keV.

$$ {}^{0}_{-1}e + {}^{0}_{1}e \longrightarrow 2\,{}^{0}_{0}\gamma $$

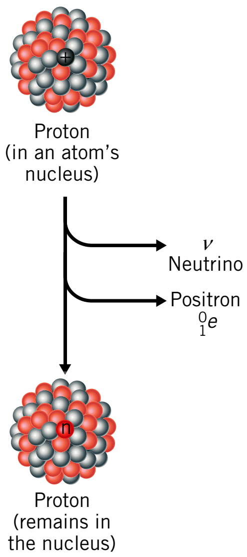


Figure 21.4 | **The emission of a positron replaces a proton by a neutron.**

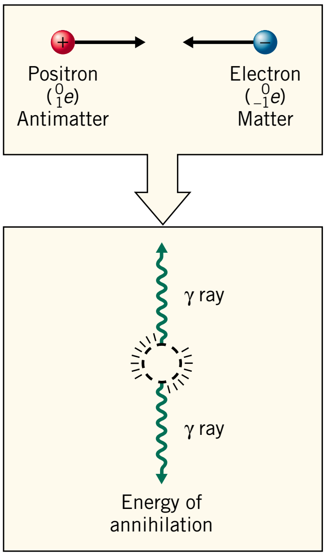

Figure 21.5 | **Gamma radiation is produced when a positron and an electron collide.** The annihilation of a positron and an electron leads to two gamma ray photons that go in exactly opposite directions.

Because a positron destroys a particle of ordinary matter (an electron), it is called a particle of antimatter. To be classified as **antimatter**, a particle must have a counterpart among one of ordinary matter, and the two must annihilate each other when they collide. For example, a neutron and an antineutron represent such a pair and annihilate each other when they come in contact.

Neutron emission, another kind of nuclear reaction, leads to a different isotope of the same element. Neutron emission occurs when an isotope has an excess of neutrons. Krypton-87, for example, decays as follows to krypton-86:

$$^{87}_{36}\mathrm{Kr} \longrightarrow {}^{86}_{36}\mathrm{Kr} + \underset{\text{neutron}}{^{1}_{0}n}$$

X-rays and Electron Capture

X rays, like gamma rays, consist of high-energy electromagnetic radiation, but their energies are usually less than those of gamma radiation. Although X rays are emitted by some synthetic radionuclides, when needed for medical diagnostic work they are generated by focusing a high-energy electron beam onto a metal target.

■ X rays used in diagnosis typically have energies of 100 keV or less.

Electron capture, yet another kind of nuclear reaction, is very rare among natural isotopes but common among synthetic radionuclides. For example, an electron can be captured from the orbital electron shell having $n = 1$ or $n = 2$ by a vanadium-50 nucleus, causing it to change to a stable ^{50}Ti nucleus. The transformation is accompanied by the emission of X rays and a neutrino.

$$^{50}_{23}\mathrm{V} + {}^{0}_{-1}e \xrightarrow{\text{Electron capture}} {}^{50}_{22}\mathrm{Ti} + \text{X rays} + \nu$$

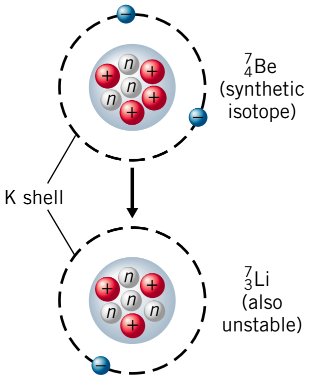

Figure 21.6 | **Electron capture.** Electron capture is the collapse of an orbital electron into the nucleus, and this changes a proton into a neutron. A gap is left in a low-energy electron orbital. When an electron drops from a higher orbital to fill the gap, an X-ray photon is emitted.

The net effect in the nucleus of electron capture is the conversion of a proton into a neutron (Figure 21.6):

$$\underset{\substack{\text{proton}\\\text{(in the nucleus)}}}{^{1}_{1}p} + \underset{\substack{\text{electron (captured}\\\text{from the 1}s\text{ orbital)}}}{^{0}_{-1}e} \longrightarrow \underset{\substack{\text{neutron}\\\text{(in the nucleus)}}}{^{1}_{0}n}$$

Electron capture does not change an atom's mass number, only its atomic number. It also leaves a hole in the first or second electron shell, and the atom emits photons of X rays as other orbital electrons drop down to fill the hole. Moreover, the nucleus that has just captured an orbital electron may be in an excited energy state and so can emit a gamma-ray photon.

Radioactive Disintegration Series

Sometimes a radionuclide does not decay directly to a stable isotope, but decays instead to another unstable radionuclide. The decay of one radionuclide after another will continue until a stable isotope forms. The sequence of such successive nuclear reactions is called a **radioactive disintegration series**. Four such series occur naturally. Uranium-238 is at the head of one of them (Figure 21.7).

The rates of decay of radionuclides vary and are usually described by specifying their half-lives, $t_{1/2}$, a topic we studied in Section 14.4. One *half-life* period in nuclear science is the time it takes for a given sample of a radionuclide to decay to one-half of its initial amount. Radioactive decay is a first-order process, so the period of time taken by one half-life is independent of the initial number of nuclei. The huge variations in the half-lives of several radionuclides are shown in Table 21.2.

Practice Exercises

21.7 | Carbon-11 is an isotope with a neutron-poor nucleus and is a positron emitter. Write the balanced nuclear equation for the decay of carbon-11. (*Hint*: What nuclide is formed when a positron is emitted?)

21.8 | Beryllium-13 is neutron rich and is a neutron emitter. Write the balanced nuclear equation for the decay of beryllium-13.

21.9 | Selenium-72 decays to arsenic-72 by electron capture, which in turn is used for PET imaging. Write a balanced nuclear equation for the decay of selenium-72.

21.4 | Band of Stability

Figure 21.8 plots all of the known isotopes of all of the elements, both stable and unstable, according to their numbers of protons and neutrons. The two curved lines in Figure 21.8 enclose a zone, called the **band of stability**, within which lie all stable nuclei. (No isotope above element 83, bismuth, is included in Figure 21.8 because none has a *stable* isotope.) Within the band of stability are also some unstable isotopes, because smooth lines cannot be drawn to exclude them.

Any isotope not represented anywhere on the array, inside or outside the band of stability, probably has a half-life too short to permit its detection. For example, an isotope with 50 neutrons and 60 protons would lie well below the band of stability and would likely be

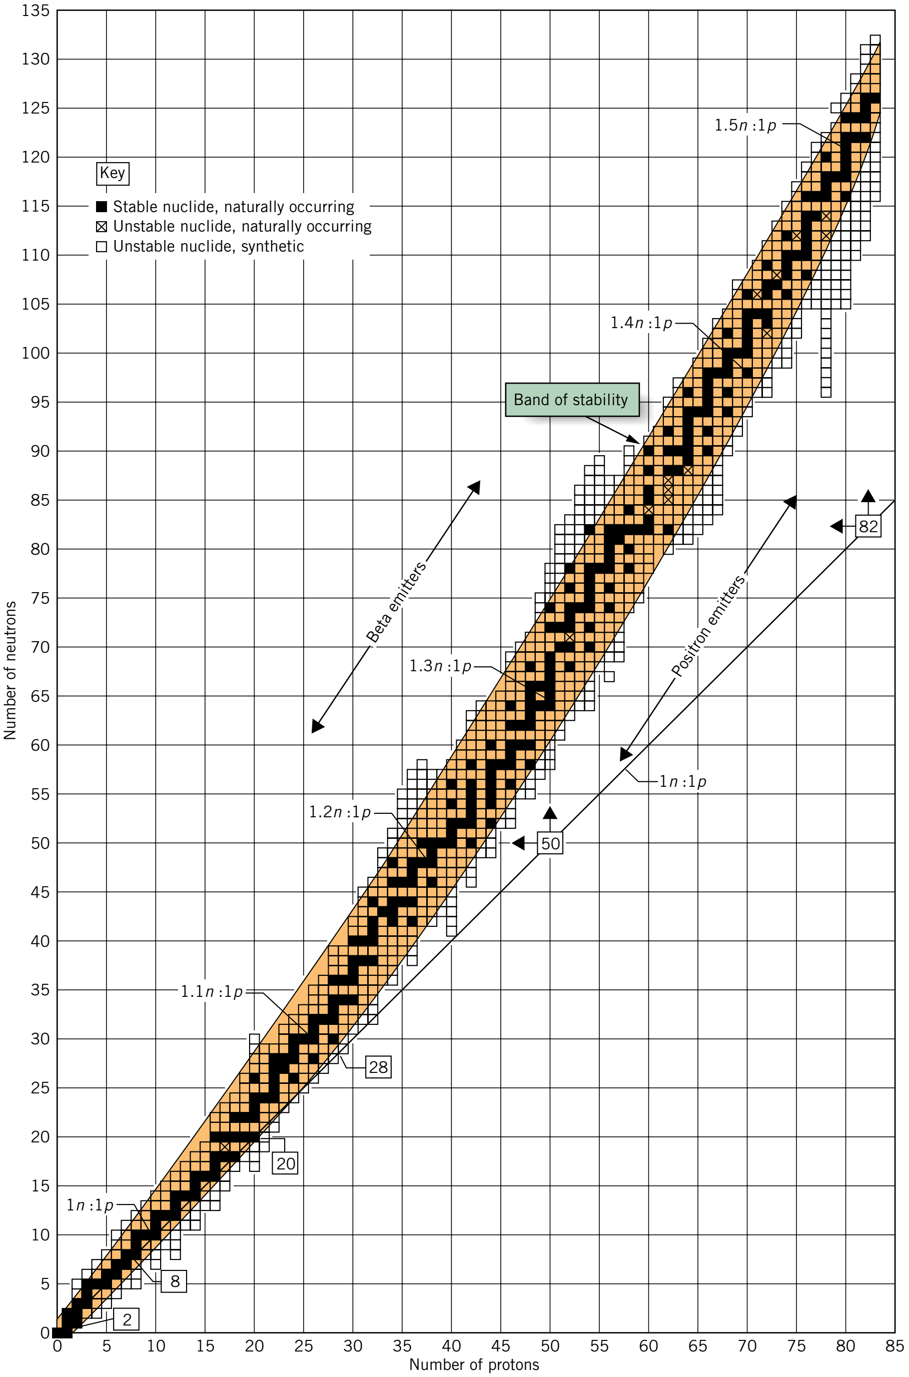

Figure 21.8 | **The band of stability.** Stable nuclei fall within a narrow band in a plot of the number of neutrons versus the number of protons. Nuclei far outside the band are too unstable to exist.

extremely unstable. Any attempt to synthesize it would likely be a waste of time and money.

Notice that the band curves slightly upward as the number of protons increases. The curvature means that the *ratio* of neutrons to protons gradually increases from 1:1, a ratio indicated by the straight line in Figure 21.8. This occurs because more protons require more neutrons to provide a compensating nuclear strong force and to dilute electrostatic proton–proton repulsions.

Nuclear Reactions of Unstable Nuclei

The isotopes with atomic numbers above 83 tend to be alpha emitters. Isotopes occurring above and to the left of the band of stability tend to be beta emitters. Isotopes lying below and to the right of the band are positron emitters. Are there any reasons for these tendencies?

Alpha Emitters

The alpha emitters, as we said, occur mostly among the radionuclides above atomic number 83. Their nuclei have too many protons, and the most efficient way to lose protons is by the loss of an alpha particle.

Beta Emitters

Beta emitters are generally above the band of stability and so have neutron-to-proton ratios that evidently are too high. By beta decay, a nucleus loses a neutron and gains a proton, thus decreasing the ratio:

$$^{1}_{0}n \longrightarrow {}^{1}_{1}p + {}^{0}_{-1}e + \overline{\nu}$$

■ The proton can also be given the symbol $^{1}_{1}\mathrm{H}$ in nuclear equations.

For example, by beta decay, fluorine-20 decreases its neutron-to-proton ratio from 11/9 to 10/10:

$$^{20}_{9}\mathrm{F} \longrightarrow {}^{20}_{10}\mathrm{Ne} + {}^{0}_{-1}e + \overline{\nu}$$

$$\frac{\text{neutron}}{\text{proton}} = \frac{11}{9} \longrightarrow \frac{10}{10}$$

The surviving nucleus, neon-10, is closer to the center of the band of stability. Figure 21.9, an enlargement of the fluorine part of Figure 21.8, explains this change

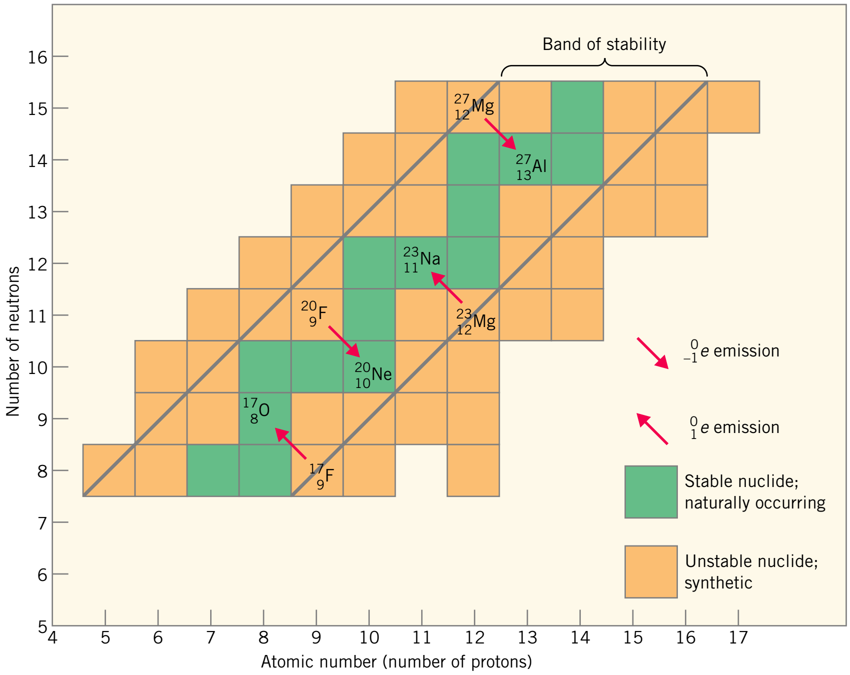

Figure 21.9 | An enlarged section of the band of stability. Beta decay from magnesium-27 and fluorine-20 reduces their neutron-to-proton ratio and moves them closer to the band of stability. Positron decay from magnesium-23 and fluorine-17 increases this ratio and moves these nuclides closer to the band of stability, too.

further. Figure 21.9 also shows how the beta decay of magnesium-27 to aluminum-27 lowers the neutron-to-proton ratio.

Positron Emitters

In nuclei with too few neutrons to be stable, positron emission increases the neutron-to-proton ratio by changing a proton into a neutron. A fluorine-17 nucleus, for example, increases its neutron-to-proton ratio, improves its stability, and moves into the band of stability by emitting a positron and a neutrino and changing to oxygen-17 (see Figure 21.9):

$$^{17}_{9}\mathrm{F} \longrightarrow {}^{17}_{8}\mathrm{O} + {}^{0}_{1}e + v$$

$$\frac{\text{neutron}}{\text{proton}} = \frac{8}{9} \longrightarrow \frac{9}{8}$$

Positron decay by magnesium-23 to sodium-23 produces a similarly favorable shift (also shown in Figure 21.9).

Odd–Even Rule

Study of the compositions of stable nuclei reveals that nature favors even numbers for protons and neutrons. This is summarized by the **odd–even rule**.

Odd–even rule

Odd–Even Rule
When the numbers of neutrons and protons in a nucleus are both even, the isotope is far more likely to be stable than when both numbers are odd.

CHEMISTRY ON THE CUTTING EDGE 21.1

Positron Emission Tomography (PET)

Positron emitters are used in an important method for studying brain function called the PET scan, for *positron emission tomography*. The technique begins by chemically incorporating positron-emitting radionuclides into molecules, like glucose, that can be absorbed by the brain directly from the blood. It's like inserting radiation generators that act from within the brain rather than focusing X rays or gamma rays from the outside. Carbon-11, for example, is a positron emitter whose atoms can be used in place of carbon-12 atoms in glucose molecules, $C_6H_{12}O_6$. (One way to prepare such glucose is to let a leafy vegetable, Swiss chard, use $^{11}CO_2$ to make the glucose by photosynthesis.)

A PET scan using tiny amounts of carbon-11 glucose detects situations where glucose is not taken up normally—for example, in manic depression, schizophrenia, and Alzheimer's disease. After the carbon-11 glucose is ingested by the patient, radiation detectors outside the body pick up the annihilation radiation produced when electrons react with positrons emitted at specifically those brain sites that use glucose. These positrons emit gamma rays in opposite directions. When the pairs of gamma rays are detected 180 degrees apart, the acquisition time can be used to back calculate exactly where the radiation came from. By mapping the locations of the brain sites using the tagged glucose, a picture showing brain function can be formed. PET scan technology, for example, demonstrated that the uptake of glucose by the brains of smokers is less than that of nonsmokers, as shown in Figure 1.

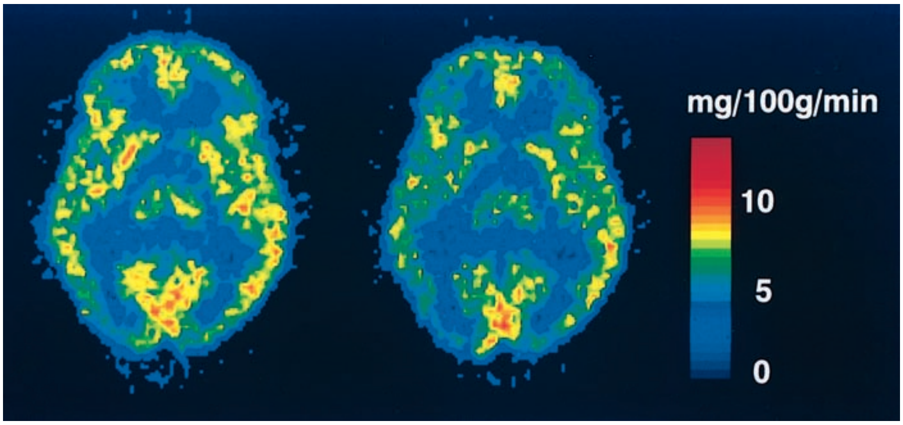

Figure 1 **Positron emission tomography (PET) in the study of brain activity.** (Left) Nonsmoker. (Right) Smoker. The PET scan reveals widespread reduction in the rate of glucose metabolism when nicotine is present. *(Courtesy of E. D. London, National Institute on Drug Abuse)*

Of the 264 stable isotopes, only five have odd numbers of both protons and neutrons, whereas 157 have even numbers of both. The rest have an odd number of one nucleon and an even number of the other. To see this, notice in Figure 21.8 how the horizontal lines with the largest numbers of dark squares (stable isotopes) most commonly correspond to even numbers of neutrons. Similarly, the vertical lines with the most dark squares most often correspond to even numbers of protons.

■ These five stable isotopes, ${}^{2}_{1}\mathrm{H}$, ${}^{6}_{3}\mathrm{Li}$, ${}^{10}_{5}\mathrm{B}$, ${}^{14}_{7}\mathrm{N}$, and ${}^{138}_{57}\mathrm{La}$, all have odd numbers of both protons and neutrons.

The odd–even rule is related to the spins of nucleons. Both protons and neutrons behave as though they spin like orbital electrons. When two protons or two neutrons have paired spins, meaning the spins are opposite, their combined energy is less than when the spins are unpaired. Only when there are even numbers of protons and neutrons can all of the spins be paired and so give the nucleus a lower energy and greater stability. The least stable nuclei tend to be those with both an odd number of protons and an odd number of neutrons.

Nuclear Magic Numbers

Another rule of thumb for nuclear stability is based on *magic numbers* of nucleons. Isotopes with specific numbers of protons or neutrons, the **magic numbers,** are more stable than the rest. The magic numbers of nucleons are 2, 8, 20, 28, 50, 82, and 126, and where they fall is shown in Figure 21.8 (except for magic number 126).

When the numbers of both protons and neutrons are the same magic number, as they are in ${}^{4}_{2}\mathrm{He}$, ${}^{16}_{8}\mathrm{O}$, and ${}^{40}_{20}\mathrm{Ca}$, the isotope is very stable. ${}^{100}_{50}\mathrm{Sn}$ also has two identical magic numbers. Although this isotope of tin is unstable, having a half-life of only several seconds, it is much more stable than nearby radionuclides, whose half-lives are in milliseconds. Thus, although tin-100 lies well outside the band of stability, it is stable enough to be observed. One stable isotope of lead, ${}^{208}_{82}\mathrm{Pb}$, involves two different magic numbers—namely, 82 protons and 126 neutrons.

■ Magic numbers do not cancel the need for a favorable neutron/proton ratio. An atom with 82 protons and 82 neutrons lies far outside the band of stability, and yet 82 is a magic number.

The existence of magic numbers supports the hypothesis that a nucleus has a shell structure with energy levels analogous to electron energy levels. Electron levels, as you already know, are associated with their own special numbers, those that equal the maximum number of electrons allowed in a principal energy level: 2, 8, 18, 32, 50, 72, and 98 (for principal levels with n equal to 1, 2, 3, 4, 5, 6, and 7, respectively). The total numbers of electrons in the atoms of the most chemically stable elements—the noble gases—also make up a special set: 2, 10, 18, 36, 54, and 86 electrons. Thus, special sets of numbers are not unique to nuclei.

Practice Exercises

21.10 | Curium-242 has 96 protons and 146 neutrons. What is the most probable form of radioactive decay for Cm-242? (*Hint*: Where would Cm-242 be found relative to the band of stability in Figure 21.8?)

21.11 | What is the most probable radioactive decay route for the iron-59 isotope of iron?

21.5 | Transmutation

The change of one isotope into another is called **transmutation**, and radioactive decay is only one cause. Transmutation can also be forced by the bombardment of nuclei with high-energy particles, such as alpha particles from natural emitters, neutrons from atomic reactors, or protons made by stripping electrons from hydrogen. To make them better bombarding missiles, protons and alpha particles can be accelerated in an electrical field (Figure 21.10). This gives them greater energy and enables them to sweep through the target atom's orbital electrons and become buried in its nucleus. Although beta particles can also be accelerated, they are repelled by a target atom's own electrons.

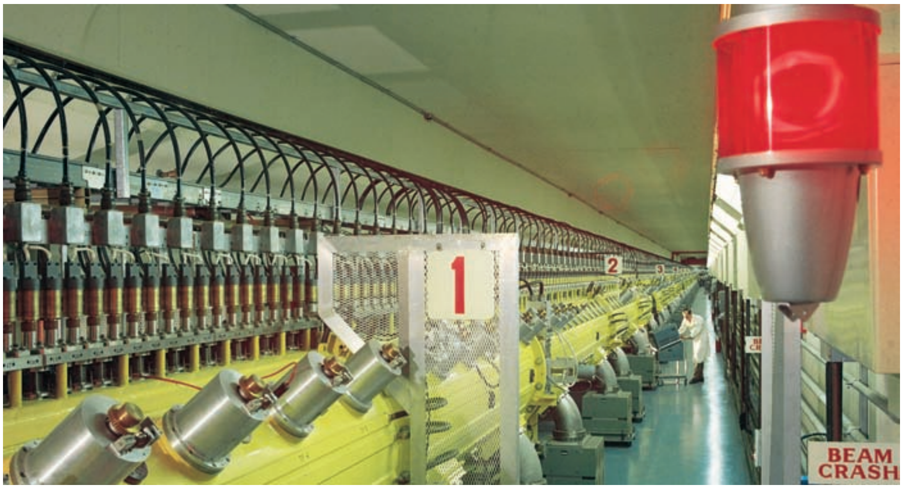

Figure 21.10 | **Linear accelerator.** In this linear accelerator at Brookhaven National Laboratory on Long Island, New York, protons can be accelerated to just under the speed of light and given up to 33 GeV of energy before they strike their target. (1 GeV = 10^9 eV) *(Courtesy Brookhaven National Laboratory)*

Compound Nuclei

■ *Compound* here refers only to the idea of *combination*, not to a chemical.

Both the energy and the mass of a bombarding particle enter the target nucleus at the moment of capture. The new nucleus, called a **compound nucleus**, has excess energy that quickly becomes distributed among all of the nucleons, but the nucleus is nevertheless rendered somewhat unstable. To get rid of the excess energy, a compound nucleus generally ejects something (e.g., a neutron, proton, or electron) and often emits gamma radiation as well. This leaves a new nucleus of an isotope different from the original target, so a transmutation has occurred overall.

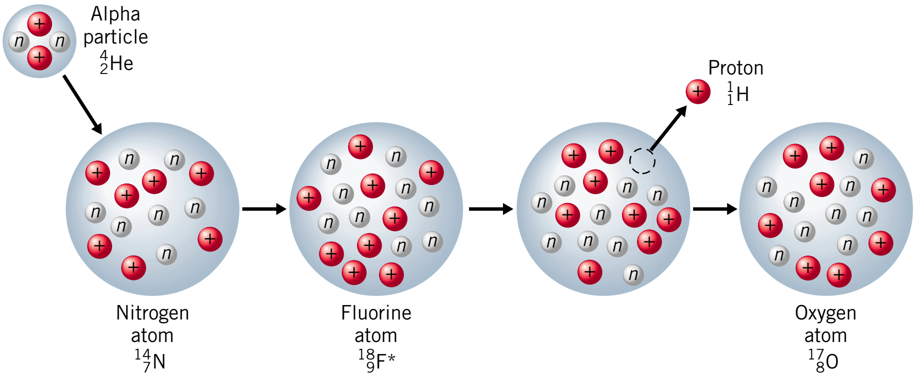
Ernest Rutherford observed the first example of artificial transmutation. When he let alpha particles pass through a chamber containing nitrogen atoms, an entirely new radiation was generated, one much more penetrating than alpha radiation. It proved to be a stream of protons (Figure 21.11). Rutherford was able to show that the protons came from the decay of the compound nuclei of fluorine-18, produced when nitrogen-14 nuclei captured bombarding alpha particles:

■ The asterisk, *, symbolizes a high-energy nucleus—a *compound nucleus.*

$$\underset{\substack{\text{alpha}\\\text{particle}}}{{}_{2}^{4}\text{He}} + \underset{\substack{\text{nitrogen}\\\text{nucleus}}}{{}_{7}^{14}\text{N}} \longrightarrow \underset{\substack{\text{fluorine}\\\text{(compound nucleus)}}}{{}_{9}^{18}\text{F}^*} \longrightarrow \underset{\substack{\text{oxygen (a rare}\\\text{but stable isotope)}}}{{}_{8}^{17}\text{O}} + \underset{\substack{\text{proton}\\\text{(high-energy)}}}{{}_{1}^{1}p}$$

Another example is the synthesis of alpha particles from lithium-7, in which protons are used as bombarding particles. The resulting compound nucleus, beryllium-8, splits in two.

$$\underset{\text{proton}}{{}_{1}^{1}p} + \underset{\text{lithium}}{{}_{3}^{7}\text{Li}} \longrightarrow \underset{\text{beryllium}}{{}_{4}^{8}\text{Be}^*} \longrightarrow \underset{\text{alpha particles}}{2\,{}_{2}^{4}\text{He}}$$



Alpha particle ${}_{2}^{4}$He
Proton ${}_{1}^{1}$H
Nitrogen atom ${}_{7}^{14}$N
Fluorine atom ${}_{9}^{18}$F*
Oxygen atom ${}_{8}^{17}$O

Figure 21.11 | **Transmutation of nitrogen into oxygen.** When the nucleus of nitrogen-14 captures an alpha particle, it becomes a compound nucleus of fluorine-18. This then expels a proton and becomes the nucleus of oxygen-17.

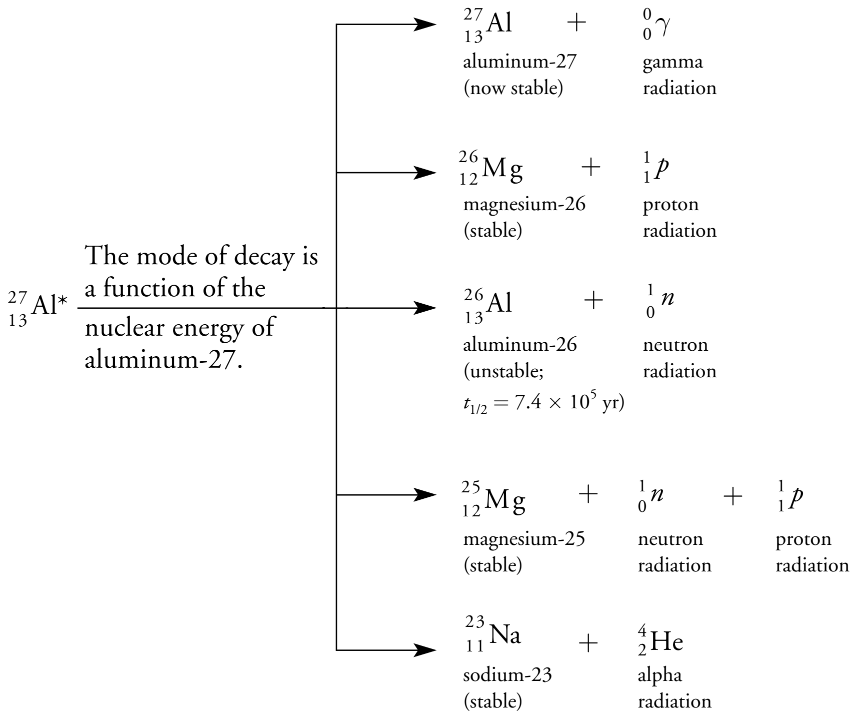
Modes of Decay

A given compound nucleus can be made in a variety of ways. Aluminum-27, for example, forms by any of the following routes:

$$
\begin{aligned}
{}^{4}_{2}\text{He} + {}^{23}_{11}\text{Na} &\longrightarrow {}^{27}_{13}\text{Al}^* \\
{}^{1}_{1}p + {}^{26}_{12}\text{Mg} &\longrightarrow {}^{27}_{13}\text{Al}^* \\
{}^{2}_{1}\text{H} + {}^{25}_{12}\text{Mg} &\longrightarrow {}^{27}_{13}\text{Al}^*
\end{aligned}
$$

■ ${}^{2}_{1}\text{H}$ is a deuteron. It is the nucleus of a deuterium atom, just as a proton is the nucleus of a hydrogen (protium) atom.

Each path gives the compound nucleus ${}^{27}_{13}\text{Al}^*$ a different amount of energy. Depending on this energy, different paths of decay are available, and all of the following routes have been observed. They illustrate how the synthesis of such a large number of synthetic isotopes, some stable and others unstable, has been possible.



${}^{27}_{13}\text{Al}^*$
The mode of decay is a function of the nuclear energy of aluminum-27.
${}^{27}_{13}\text{Al}$ + ${}^{0}_{0}\gamma$
aluminum-27 (now stable)
gamma radiation
${}^{26}_{12}\text{Mg}$ + ${}^{1}_{1}p$
magnesium-26 (stable)
proton radiation
${}^{26}_{13}\text{Al}$ + ${}^{1}_{0}n$
aluminum-26 (unstable; $t_{1/2} = 7.4 \times 10^5$ yr)
neutron radiation
${}^{25}_{12}\text{Mg}$ + ${}^{1}_{0}n$ + ${}^{1}_{1}p$
magnesium-25 (stable)
neutron radiation
proton radiation
${}^{23}_{11}\text{Na}$ + ${}^{4}_{2}\text{He}$
sodium-23 (stable)
alpha radiation

Synthetic Elements

Over a thousand isotopes have been made by transmutations. Most, nearly 900 in number, do not occur naturally; they appear in the band of stability (Figure 21.8) as open squares. The naturally occurring radioactive isotopes above atomic number 83 all have very long half-lives. Others might have existed, but their half-lives probably were too short to permit them to last into our era. All of the elements beyond neptunium (atomic number 93 and higher, known as the **transuranium elements**) are synthetic. Elements from atomic numbers 93 to 103 complete the actinide series of the periodic table, which starts with element 90 (thorium). Beyond this series, elements 104 through 118 have also been made.

To make the heaviest elements, bombarding particles larger than neutrons are used, such as alpha particles or the nuclei of heavier atoms. For example, element 110—darmstadtium, Ds—was made from the compound nucleus formed by the fusion of nickel-62 and lead-208. Darmstadtium-270 decayed to darmstadtium-269 when a neutron was ejected:

■ Element 110 was named after the place of its discovery, Darmstadt, Germany. Element 111 was named in honor of Wilhelm Roentgen, who discovered X rays in 1895.

$${}^{62}_{28}\text{Ni} + {}^{208}_{82}\text{Pb} \longrightarrow {}^{270}_{110}\text{Ds} \longrightarrow {}^{269}_{110}\text{Ds} + {}^{1}_{0}n$$

Similarly, some atoms of element 111 (roentgenium, Rg) formed when a neutron was lost from the compound nucleus made by bombarding bismuth-209 with nickel-64. Most of these heavy atoms are extremely unstable, with half-lives measured in fractions of milliseconds. An exception is element 114; two isotopes have been detected with half-lives reported to be in the tens of seconds.

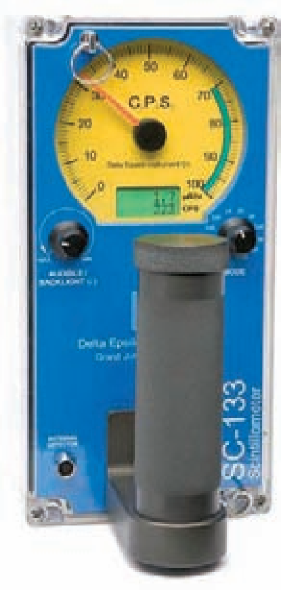


Figure 21.12 | **Scintillation probe.** Energy received from radiations striking the phosphor at the end of this probe is processed by the photomultiplier unit and the counts are measured on the dial. *(Delta Epsilon Instruments, Inc.)*

21.6 | Measuring Radioactivity

Atomic radiation is often described as **ionizing radiation** because it creates ions by knocking electrons from molecules in the matter through which the radiation travels. The generation of ions is behind some of the devices for detecting radiation.

The Geiger–Müller tube, one part of a **Geiger counter**, detects beta and gamma radiation having energy high enough to penetrate the tube's window. Inside the tube is a gas under low pressure in which ions form when radiation enters. The ions permit a pulse of electricity to flow, which activates a current amplifier, a pulse counter, and an audible click.

A **scintillation counter** (Figure 21.12) contains a sensor composed of a substance called a *phosphor* that emits a tiny flash of light when struck by a particle of ionizing radiation. These flashes can be magnified electronically and automatically counted.

The darkening of a photographic film exposed to radiation over a period of time is proportional to the total quantity of radiation received. **Film dosimeters** work on this principle (Figure 21.13), and people who work near radiation sources use them. Each person keeps a log of total exposure, and if a predetermined limit is exceeded, the worker must be reassigned to an unexposed workplace.

Units of Radiation

The **activity** of a radioactive material is the number of disintegrations per second. The SI unit of activity is the **becquerel (Bq)**, and it equals one disintegration per second. For example, a liter of air has an activity of about 0.04 Bq, due to the carbon-14 in its carbon dioxide. A gram of natural uranium has an activity of about 2.6×10^4 Bq.

■ The becquerel is named after Henri Becquerel (1852–1908), the discoverer of radioactivity, who won a Nobel Prize in 1903.

The **curie (Ci)**, named after Marie Curie, who discovered radium, is an older unit, being equal to the activity of a 1.0 g sample of radium-226:

$$1 \text{ Ci} = 3.7 \times 10^{10} \text{ disintegrations s}^{-1} = 3.7 \times 10^{10} \text{ Bq} \quad \textbf{(21.3)}$$

Marie Curie (1867–1934); Nobel Prizes 1903 (physics) and 1911 (chemistry) *(Courtesy College of Physicians of Philadelphia)*

Figure 21.13 | **Badge dosimeter.** *(Cliff Moore/Photo Researchers, Inc.)*

For a sufficiently large sample of a radioactive material, the activity is experimentally found to be proportional to the number of radioactive nuclei, N:

$$\text{activity} = k\,N$$

The constant of proportionality, k, is called the **decay constant**. The decay constant is characteristic of the particular radioactive nuclide, and it gives the activity per nuclide in the sample. Since activity is the number of disintegrations per second, and therefore the change in the number of nuclei per second, we can write

■ In this discussion, a *disintegration* refers to a single nuclear change that results in the emission of a burst of radiation, which could consist of an alpha particle, beta particle, or gamma photon.

$$\text{activity} = -\frac{\Delta N}{\Delta t} = k\,N \tag{21.4}$$

TOOLS

Law of radioactive decay

which is called the **law of radioactive decay**.[1] The law shows that radioactive decay is a first-order kinetic process, and the decay constant is really just a first-order rate constant in terms of number of nuclei, rather than concentrations.

Recall from Chapter 14 that the half-life of a first-order reaction is given by Equation 14.7:

$$t_{1/2} = \frac{\ln\,2}{k}$$

TOOLS

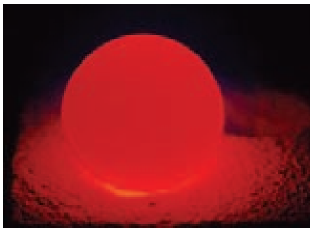
Half-life of a radionuclide

If we know the half-life of a radioisotope, we can use this relationship to compute its decay constant and also the activity of a known mass of the radioisotope, as Example 21.2 demonstrates.

Example 21.2

Using the Law of Radioactive Decay

Deep-space probes such as NASA's Cassini spacecraft need to keep their instruments warm enough to operate effectively. Since solar power is not available in the darkness of deep space, these craft generate heat from the radioactive decay of small pellets of plutonium dioxide, pictured in the margin. Each pellet is about the size of a pencil eraser and weighs about 2.7 g. If the pellets are pure PuO_2, with the plutonium being ^{238}Pu, what is the activity of one of the fuel pellets, in becquerels?



U.S. Department of Energy/ Photo Researchers

■ **Analysis:** We are looking for the activity of a fuel pellet, and to do this, we will need to know how much material there is and the rate of decay. We can find the number of ^{238}Pu atoms in the sample and then we will need to find the rate constant, k, from the half-life of ^{238}Pu, since it is a first-order process.

■ **Assembling the Tools:** The tool for finding the activity is Equation 21.4. But to use the equation, we'll need the decay constant, k, and the number of plutonium-238 atoms, N, in the fuel pellet.

From Table 21.2, the half-life of ^{238}Pu is 87.8 years. We can rearrange Equation 14.7 to compute the decay constant k from the half-life:

$$k = \frac{\ln\,2}{t_{1/2}}$$

We'll want to convert the decay constant into seconds, because the becquerel is defined as disintegrations per second.

We know that the pellet contains 2.7 g of PuO_2. To calculate N, we'll have to perform the following stoichiometric conversion:

$$2.7 \text{ g } PuO_2 \Leftrightarrow \text{? atoms Pu}$$

---

[1] The minus sign is introduced to make the activity a positive number, since the change in the number of radioactive nuclei, ΔN, is negative.

The tools here come from Chapter 4. We'll use the molar mass of PuO_2 (270 g mol^{-1}) to find moles of PuO_2, the chemical formula to relate this to moles of Pu, and then Avogadro's number to find the number of atoms of Pu. Our strategy is to perform the following conversions:

$$2.7\ \mathrm{g\ PuO_2} \longrightarrow \mathrm{mol\ PuO_2} \longrightarrow \mathrm{mol\ Pu} \longrightarrow \mathrm{atoms\ Pu}$$

■ **Solution:** First, let's compute the decay constant from the half-life. We must convert the half-life into seconds:

$$87.8\ \cancel{\mathrm{years}} \times \frac{365\ \cancel{\mathrm{days}}}{1\ \cancel{\mathrm{year}}} \times \frac{24\ \cancel{\mathrm{hours}}}{1\ \cancel{\mathrm{day}}} \times \frac{60\ \cancel{\mathrm{min}}}{1\ \cancel{\mathrm{hour}}} \times \frac{60\ \mathrm{s}}{1\ \cancel{\mathrm{min}}} = 2.77 \times 10^9\ \mathrm{s}$$

Now, we can solve Equation 14.7 for the decay constant:

$$\begin{aligned} k &= \frac{\ln 2}{t_{1/2}} \\ &= \frac{0.693}{2.77 \times 10^9\ \mathrm{s}} \\ &= 2.50 \times 10^{-10}\ \mathrm{s}^{-1} \end{aligned}$$

Next, we need the number of ^{238}Pu atoms in the fuel pellet:

$$2.7\ \cancel{\mathrm{g\ PuO_2}} \times \frac{1\ \cancel{\mathrm{mol\ PuO_2}}}{270\ \cancel{\mathrm{g\ PuO_2}}} \times \frac{1\ \cancel{\mathrm{mol\ Pu}}}{1\ \cancel{\mathrm{mol\ PuO_2}}} \times \frac{6.02 \times 10^{23}\ \mathrm{atoms\ Pu}}{1\ \cancel{\mathrm{mol\ Pu}}}$$
$$= 6.0 \times 10^{21}\ \mathrm{atoms\ Pu}$$

From the law of radioactive decay, Equation 21.4, the activity of the fuel pellet is

$$\mathrm{activity} = kN = (2.50 \times 10^{-10}\ \mathrm{s}^{-1}) \times (6.0 \times 10^{21}\ \mathrm{atoms\ Pu}) = 1.5 \times 10^{12}\ \mathrm{atoms\ Pu/s}$$

Since the becquerel is defined as the number of disintegrations per second, and each plutonium atom corresponds to one disintegration, we can report the activity as 1.5×10^{12} Bq.

■ **Is the Answer Reasonable?** There is no easy way to check the size of the decay constant beyond checking the arithmetic. The number of Pu atoms in the pellet makes sense, because if we have 2.7 g PuO_2 and the formula mass is 270 g mol^{-1}, we have 1/100th of a mole of PuO_2 and so 1/100 a mole of Pu. We should have (1/100) of 6.02×10^{23} atoms, or 6.02×10^{21} atoms of Pu.

The fuel pellet has about 40 times the activity of a gram of radium-226, as indicated by Equation 21.3, so the activity of ^{238}Pu per gram is about 15 times the activity of ^{226}Ra per gram.

Practice Exercises

21.12 | A 2.00 g sample of a mixture of plutonium with a nonradioactive metal has an activity of 6.22×10^{11} Bq. What is the percentage by mass of plutonium in the sample? (*Hint*: How many atoms of Pu are in the sample?)

21.13 | The EPA limit for radon-222 is 4 pCi (picocuries) per liter of air. How many atoms of ^{222}Rn per liter of air will produce this activity?

■ The *gray* is named after Harold Gray, a British radiologist. *Rad* stands for **r**adiation **a**bsorbed **d**ose.

Nuclear radiation can have varying effects depending on the energy of the radiation and its ability to be absorbed. The **gray (Gy)** is the SI unit of *absorbed dose*, and 1 gray corresponds to 1 joule of energy absorbed per kilogram of absorbing material. The **rad** is an older unit of absorbed dose, where 1 rad is the absorption of 10^{-2} joule per kilogram of tissue. Thus, 1 Gy equals 100 rad. In terms of danger, if every individual in a large population received 4.5 Gy (450 rad), roughly half of the population would die in 60 days.

The gray is not a good basis for comparing the biological effects of radiation in tissue, because these effects depend not just on the energy absorbed but also on the kind of radiation and the tissue itself. The **sievert (Sv)**, the SI unit of *dose equivalent,* was invented to meet this problem. The **rem** is an older unit of dose equivalent, one still used in medicine. Its value is generally taken to equal 10^{-2} Sv. The U.S. government has set guidelines of 0.3 rem per week as the maximum exposure workers may receive. (For comparison, a chest X ray typically involves about 0.004 rem or 4 mrem.) Table 21.3 lists some sources of radiation and their doses.

■ *Rem* stands for **r**oentgen **e**quivalent for **m**an, where the *roentgen* is a unit related to X ray and gamma radiation.

Radiation and Living Tissue

A whole-body dose of 25 rem (0.25 Sv) induces noticeable changes in human blood. A set of symptoms called *radiation sickness* develops at about 100 rem, becoming severe at 200 rem. Among the symptoms are nausea, vomiting, a drop in the white cell count, diarrhea, dehydration, prostration, hemorrhaging, and loss of hair. If each person in a large population absorbed 400 rem, half would die in 60 days. A 600 rem dose would kill everyone in the group in a week. Many workers received at least 400 rem in the moments following the steam explosion that tore apart one of the nuclear reactors at the Ukraine energy park near Chernobyl in 1986.

Table 21.3 Sources of Radiation

Radiation Source	Dose
Living near a nuclear power station	<0.001 rem
Chest X ray	0.004 rem
Cosmic radiation at sea level	0.024 rem
Terrestrial radioactivity	0.028 rem
Mammogram	0.030 rem
Natural radioactivity in the body	0.040 rem
Cosmic radiation living in Denver	0.050 rem
Diagnostic radiology	0.050 rem
Radon in average home	0.200 rem
Gastrointestinal series	1.400 rem

Data from: U.S. EPA Office of Air and Radiation, EPA-402-K-07-006, May 2007.

Free Radical Formation

Even small absorbed doses can be biologically harmful. The danger does not lie in the heat energy associated with the dose, which is usually very small. Rather, the harm is in the ability of ionizing radiation to create unstable ions or neutral species with odd (unpaired) electrons, species that can set off other reactions. Water, for example, can interact as follows with ionizing radiation:

$$\mathrm{H{-}\underset{\cdot\cdot}{\overset{\cdot\cdot}{O}}{-}H} \xrightarrow{\text{radiation}} \left[\mathrm{H{-}\underset{\cdot\cdot}{\overset{\cdot}{O}}{-}H}\right]^{+} + {}^{\;\,0}_{-1}e$$

The new cation, $\left[\mathrm{H{-}\underset{\cdot\cdot}{\overset{\cdot}{O}}{-}H}\right]^{+}$, is unstable and one breakup path is

$$\left[\mathrm{H{-}\underset{\cdot\cdot}{\overset{\cdot}{O}}{-}H}\right]^{+} \longrightarrow \underset{\text{proton}}{\mathrm{H}^{+}} + \underset{\substack{\text{hydroxyl}\\ \text{radical}}}{:\mathrm{\underset{\cdot\cdot}{\overset{\cdot}{O}}{-}H}}$$

The proton might pick up a stray electron to become a hydrogen atom, H•.

Both the hydrogen atom and the hydroxyl radical are examples of **free radicals** (often simply called *radicals*), which are neutral or charged particles having one or more unpaired electrons. They are chemically very reactive. What they do once formed depends on the other chemical species nearby, but radicals can set off a series of totally undesirable chemical reactions inside a living cell. This is what makes the injury from absorbed radiation of far greater magnitude than what the energy alone could inflict. A dose of 600 rem is a lethal dose in a human, but the same dose absorbed by pure water causes the ionization of only one water molecule in every 36 million.

Background Radiation

The presence of radionuclides in nature makes it impossible for us to be free from all exposure to ionizing radiation. Cosmic rays composed of high-energy photons shower on us from the sun and interstellar space. They interact with the air's nitrogen molecules to produce carbon-14, a beta emitter, which enters the food chain via photosynthesis, which converts CO_2 to sugars and starch. From the earth's crust comes the radiation of radionuclides naturally present. The top 40 cm of earth's soil holds an average of 1 gram of radium, an alpha emitter, per square kilometer. Naturally occurring potassium-40, a beta emitter, adds its radiation wherever potassium ions are found in the body. The presence of carbon-14 and potassium-40 together produce about 5×10^5 nuclear disintegrations per minute inside an adult human. Radon gas seeps into basements from underground formations. In fact, the World Nuclear Organization estimates that a little over half of the radiation we experience, on average, is from radon-222 and its decay products.

Diagnostic X rays, both medical and dental, also expose us to ionizing radiation. All of these sources produce a combined **background radiation** that averages 360 mrem per person annually in the United States. The averages are roughly 82% from natural radiation and 18% from medical sources.

Radiation Protection

Gamma radiation and X rays are so powerful that they are effectively shielded only by very dense materials, like lead. Otherwise, one should stay as far from a source as possible, because the intensity of radiation diminishes with the *square* of the distance. This relationship is the **inverse square law**, which can be written mathematically as follows, where *d* is the distance from the source:

$$\text{Radiation intensity} \propto \frac{1}{d^2}$$

■ When the ratio is taken, the proportionality constant cancels, so we don't have to know what its value is.

When the intensity, I_1, is known at distance d_1, then the intensity I_2 at distance d_2 can be calculated by Equation 21.5:

TOOLS

Inverse square law

$$\frac{I_1}{I_2} = \frac{d_2^2}{d_1^2} \tag{21.5}$$

This law applies only to a small source that radiates equally in all directions, with no intervening shields.

Practice Exercises

21.14 | If the intensity of radiation from a radioactive sources is 4.8 units at a distance of 5.0 m, how far from the source would you have to move to reduce the intensity to 0.30 unit? (*Hint*: How does intensity vary with distance?)

21.15 | If an operator 10 m from a small source is exposed to 1.4 units of radiation, what will be the intensity of the radiation if he moves to 1.2 m from the source?

21.7 | Medical and Analytical Applications of Radionuclides

Because chemical properties depend on the number and arrangement of orbital electrons and not on the specific makeup of nuclei, both radioactive and stable isotopes of an element behave the same chemically. This fact forms the basis for some uses of radionuclides. The chemical and physical properties enable scientists to get radionuclides into place in systems of interest. Then the radiation is exploited for medical or analytical purposes. Tracer analysis, neutron activation analysis, and radiological dating are three examples we will discuss.

Tracer Analysis

In **tracer analysis,** the chemical form and properties of a radionuclide enable the system to distribute it to a particular location. The intensity of the radiation then tells something about how that site is working. In the form of the iodide ion, for example, iodine-131 is carried by the body to the thyroid gland, the only user of iodide ion in the body. The thyroid takes up the iodide ion to synthesize the hormone thyroxine. The activity of the thyroid can be monitored since an underactive thyroid gland is unable to concentrate iodide ion normally and will emit less intense radiation than a normal thyroid.

Tracer analyses are also used to pinpoint the locations of brain tumors, which are uniquely able to concentrate the pertechnetate ion, TcO_4^-, made from technetium-99*m*.[2] This strong gamma emitter, which resembles the chloride ion in some respects, is one of the most widely used radionuclides in medicine.

■ Technetium-99*m* is also used in bone scans to detect and locate bone cancer. Active cancer sites concentrate the Tc, which can be detected using external scanning devices.

Neutron Activation Analysis

A number of stable nuclei can be changed into emitters of gamma radiation by capturing neutrons, and this makes possible a procedure called **neutron activation analysis**. Neutron capture followed by gamma emission can be represented by the following equation, where *A* is a mass number and *X* is a hypothetical atomic symbol:

$$^{A}X \;+\; {}^{1}_{0}n \;+\; \longrightarrow \; {}^{(A+1)}X^{*} \;\longrightarrow\; {}^{(A+1)}X \;+\; {}^{0}_{0}\gamma$$

^{A}X	$^{1}_{0}n$	$^{(A+1)}X^{*}$	$^{(A+1)}X$	$^{0}_{0}\gamma$
isotope of element *X* being analyzed	neutron	compound nucleus (unstable)	more stable form of a new isotope of *X*	gamma radiation

A neutron-enriched compound nucleus emits gamma radiation at its own set of unique frequencies, and these sets of frequencies are now known for each isotope. (Not all isotopes, however, become gamma emitters by neutron capture.) The element can be identified by measuring the specific *frequencies* of gamma radiation emitted. The *concentration* of the element can be determined by measuring the *intensity* of the gamma radiation.

Neutron activation analysis is so sensitive that concentrations as low as $10^{-9}\%$ can be determined. A museum might have a lock of hair of some famous but long-dead person suspected of having been slowly murdered by arsenic poisoning. If so, some arsenic would be in the hair, and neutron activation analysis could find it without destroying the specimen of hair.

Radiological Dating

The determination of the age of a geological deposit or an archaeological find by the use of the radionuclides that are naturally present is called **radiological dating**. It is based partly on the premise that the half-lives of radionuclides have been constant throughout the entire geological period. This premise is supported by the finding that half-lives are insensitive to all environmental forces such as heat, pressure, magnetism, or electrical stresses. Radiological dating of archaeological objects by carbon-14 analyses was described in Chapter 14 (page 659).

In geological dating, a pair of isotopes is sought that are related as a "parent" to a "daughter" in a radioactive disintegration series, like the uranium-238 series (Figure 21.7). Uranium-238 (as "parent") and lead-206 (as "daughter") have thus been used as a radiological dating pair of isotopes. The half-life of uranium-238 is very long, a necessary criterion for geological dating. Put simply, after the concentrations of uranium-238 and lead-206 are determined in a rock specimen, the *ratio* of the concentrations together with the half-life of uranium-238 is used to calculate the age of the rock. This works since there is no lead in magma, and rocks come from magma.

Probably the most widely used isotopes for dating rock are the potassium-40/argon-40 pair. Potassium-40 is a naturally occurring radionuclide with a half-life nearly as long as that of uranium-238. One of its modes of decay is electron capture in which argon-40 is formed:

$$^{40}_{19}K + {}^{0}_{-1}e \longrightarrow {}^{40}_{18}Ar$$

---

[2] The *m* in technetium-99*m* means that the isotope is in a metastable form. Its nucleus is at a higher energy level than the nucleus in technetium-99, to which technetium-99*m* decays.

The argon produced by this reaction remains trapped within the crystal lattices of the rock and is freed only when the rock sample is melted. How much has accumulated is measured with a mass spectrometer (page 66), and the observed ratio of argon-40 to potassium-40, together with the half-life of the parent, permits the age of the specimen to be estimated. Because the half-lives of uranium-238 and potassium-40 are so long, samples have to be at least 300,000 years old for either of the two parent–daughter isotope pairs to provide reliable results.

■ For ^{238}U, $t_{1/2} = 4.51 \times 10^9$ yr
For ^{40}K, $t_{1/2} = 1.3 \times 10^9$ yr

Carbon-14 and the Asian Brown Cloud

As discussed in detail in Chapter 14, measurements of the ^{14}C to ^{12}C ratio in an ancient organic sample, such as an object made of wood or bone, permits calculation of the sample's age.

There are two approaches to carbon-14 dating. The older method, introduced by its discoverer, Willard F. Libby (Nobel Prize in Chemistry, 1960), measures the *radioactivity* of a sample taken from the specimen. The radioactivity is proportional to the concentration of carbon-14.

■ For carbon dating to be accurate, extraordinary precautions must be taken to ensure that specimens are not contaminated by more recent sources of carbon or carbon compounds.

The newer and current method of carbon-14 dating relies on a mass spectrometer that is able to separate the atoms of carbon-14 from the other isotopes of carbon (as well as from nitrogen-14) *and count all of them*, not just the carbon-14 atoms that decay. This approach permits the use of smaller samples (0.5–5 mg vs. 1–20 g for the Libby method), it works at much higher efficiencies, and it gives more precise dates. Objects of up to 70,000 years old can be dated, but the highest accuracy involves systems no older than 7000 years.

Using ^{14}C measurements, scientists determined the origin of the carbon-containing aerosols in the Asian brown cloud. If the particles came from the burning of coal and oil, then the amount of ^{14}C in the sample would be very small since coal and oil are more than 70,000 years old. On the other hand, if the amount of ^{14}C in the samples were measurable, then the age of the carbon could be determined. In this case, the carbon was "young" carbon, so the source of the carbon-containing aerosols had to be recently harvested biomass, or plants.

21.8 | Nuclear Fission and Fusion

Nuclear fission is a process whereby a heavy atomic nucleus splits into two lighter fragments. **Nuclear fusion**, on the other hand, is a process whereby very light nuclei join to form a heavier nucleus. Both processes release large amounts of energy, as we will discuss shortly.

Nuclear Fission Reactions

Because of their electrical neutrality, neutrons penetrate an atom's electron cloud relatively easily and so are able to enter the nucleus. Enrico Fermi discovered in the early 1930s that even slow-moving, *thermal neutrons* can be captured. (Thermal neutrons are those whose average kinetic energy is the same as any other group of particles at room temperature.) When he directed them at a uranium target, he discovered that several different species of nuclei, all much lighter than uranium, were produced.

Without realizing it, what Fermi had observed was the nuclear fission of one particular isotope, uranium-235, present in small concentrations in naturally occurring uranium. The general reaction can be represented as follows.

$$^{235}_{92}\mathrm{U} + ^{1}_{0}n \longrightarrow X + Y + b\,^{1}_{0}n$$

X and Y can be a large variety of nuclei with intermediate atomic numbers. Over 30 have been identified. The coefficient b has an average value of 2.47, the average number of neutrons produced by fission events. A typical specific fission is

$$^{235}_{92}\mathrm{U} + ^{1}_{0}n \longrightarrow ^{236}_{92}\mathrm{U}^* \longrightarrow ^{94}_{36}\mathrm{Kr} + ^{139}_{56}\mathrm{Ba} + 3\,^{1}_{0}n$$

What actually undergoes fission is the compound nucleus of uranium-236. It has 144 neutrons and 92 protons, giving it a neutron-to-proton ratio of roughly 1.6. Initially, the emerging krypton and barium isotopes have the same ratio, and this is much too high for them. The neutron-to-proton ratio for stable isotopes with 36 to 56 protons is nearer 1.2 to 1.3 (Figure 21.8). Therefore, the initially formed, neutron-rich krypton and barium nuclides promptly eject neutrons, called *secondary neutrons,* that generally have much higher energies than thermal neutrons.

An isotope that can undergo fission after neutron capture is called a **fissile isotope**. The naturally occurring fissile isotope of uranium used in reactors is uranium-235, whose abundance among the uranium isotopes today is only 0.72%. Two other fissile isotopes, uranium-233 and plutonium-239, can be made in nuclear reactors.

Nuclear Chain Reactions

The secondary neutrons released by fission become thermal neutrons as they are slowed by collisions with surrounding materials. They can now be captured by unchanged uranium-235 atoms. Because each fission event produces, on the average, more than two new neutrons, the potential exists for a **nuclear chain reaction** (Figure 21.14). A *chain reaction* is a self-sustaining process whereby products from one event cause one or more repetitions of the process.

If the sample of uranium-235 is small enough, the loss of neutrons to the surroundings is sufficiently rapid to prevent a chain reaction. However, at a certain **critical mass** of uranium-235 (i.e., about 50 kilograms), this loss of neutrons is insufficient to prevent a sustained reaction. A virtually instantaneous fission of the sample ensues—in other words, an atomic bomb explosion. To trigger an atomic bomb, therefore, two subcritical masses of uranium-235 (or plutonium-239) are forced together to form a critical mass.

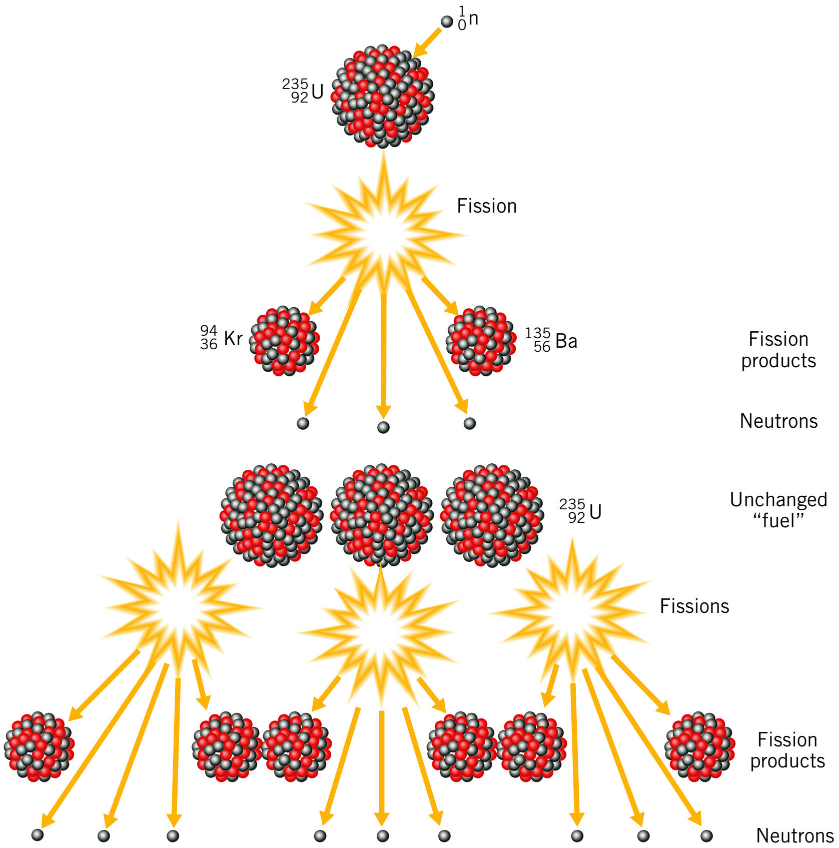


Figure 21.14 | **Nuclear chain reaction.** Whenever the concentration of a fissile isotope is high enough (i.e., at or above the critical mass), the neutrons released by one fission can be captured by enough unchanged nuclei to cause more than one additional fission event. In civilian nuclear reactors, the fissile isotope is too dilute for this to get out of control. In addition, control rods of nonfissile materials that are able to capture excess neutrons can be inserted or withdrawn from the reactor core to make sure that the heat generated can be removed as fast as it forms.

Nuclear Power

The binding energy per nucleon (Figure 21.1) in uranium-235 (about 7.6 MeV) is less than the binding energies of the new nuclides (about 8.5 MeV). The net change for a single fission event can be calculated as follows (where we intend only *two* significant figures in each result):

■ 1 MeV = 1.602×10^{-13} J

Binding energy in krypton-94:

$$(8.5 \text{ MeV/nucleon}) \times 94 \text{ nucleons} = 800 \text{ MeV}$$

Binding energy in barium-139:

$$(8.5 \text{ MeV/nucleon}) \times 139 \text{ nucleons} = \underline{1200 \text{ MeV}}$$

$$\text{Total binding energy of products:} \quad 2000 \text{ MeV}$$

Binding energy in uranium-235:

$$(7.6 \text{ MeV/nucleon}) \times 235 \text{ nucleons} = 1800 \text{ MeV}$$

The difference in total binding energy is (2000 MeV − 1800 MeV), or 200 MeV (3.2×10^{-11} J), which has to be taken as just a rough calculation. This is the energy released by each fission event going by the equation given. The energy produced by the fission of 1 kg (4.25 mole) of uranium-235 is calculated to be roughly 8×10^{13} J, enough to keep a 100 watt light bulb in energy for 3000 years.

■ The energy available from 1 kg of uranium-235 is equivalent to the energy of combustion of 3000 tons of soft coal or 13,200 barrels of oil.

Nuclear Power Plants

Virtually all civilian nuclear power plants throughout the world operate on the same general principles. The energy of fission is used, as heat, either directly or indirectly to increase the pressure of some gas that then drives an electrical generator.

The heart of a nuclear power plant is the *reactor,* where fission takes place in the *fuel core*. The nuclear fuel is generally uranium oxide, enriched to 2–4% in uranium-235 and formed into glasslike pellets. These are housed in long, sealed metal tubes called *cladding*. Groups of tubes are assembled with spacers that permit a coolant to circulate around the tubes. A reactor has several such assemblies in its fuel core. The coolant carries away the heat of fission.

There is no danger of a nuclear power plant undergoing an atomic bomb explosion. An atomic bomb requires uranium-235 at a concentration of 85% or greater or plutonium-239 at a concentration of at least 93%. The concentration of fissile isotopes in a reactor is in the range of 2 to 4%, and much of the remainder is the common, nonfissile uranium-238. However, if the coolant fails to carry away the heat of fission, the reactor core can melt, and the molten mass might even go through the thick-walled containment vessel in which the reactor is kept. Alternatively, the high heat of the fission might split molecules of coolant water into hydrogen and oxygen, which, on recombining, would produce an immense explosion.

To convert secondary neutrons to thermal neutrons, the fuel core has a *moderator*, which is the coolant water itself in nearly all civilian reactors. Collisions between secondary neutrons and moderator molecules heats up the moderator. This heat energy eventually generates steam that enables an electric turbine to run. Ordinary water is a good moderator, but so are heavy water (D_2O) and graphite.

■ D_2O is deuterium oxide. Deuterium is an isotope of hydrogen, $^{2}_{1}H$.

Two main types of reactors dominate civilian nuclear power: the *boiling water reactor* and the *pressurized water reactor*. Both use ordinary water as the moderator and so are sometimes called *light water reactors*. Roughly two-thirds of the reactors in the United States are the pressurized-water type (Figure 21.15). Such a reactor has two loops, and water circulates in both. The primary loop moves water through the reactor core, where it picks up thermal energy from fission. The water is kept in the *liquid* state by being under high pressure (hence the name *pressurized*-water reactor).

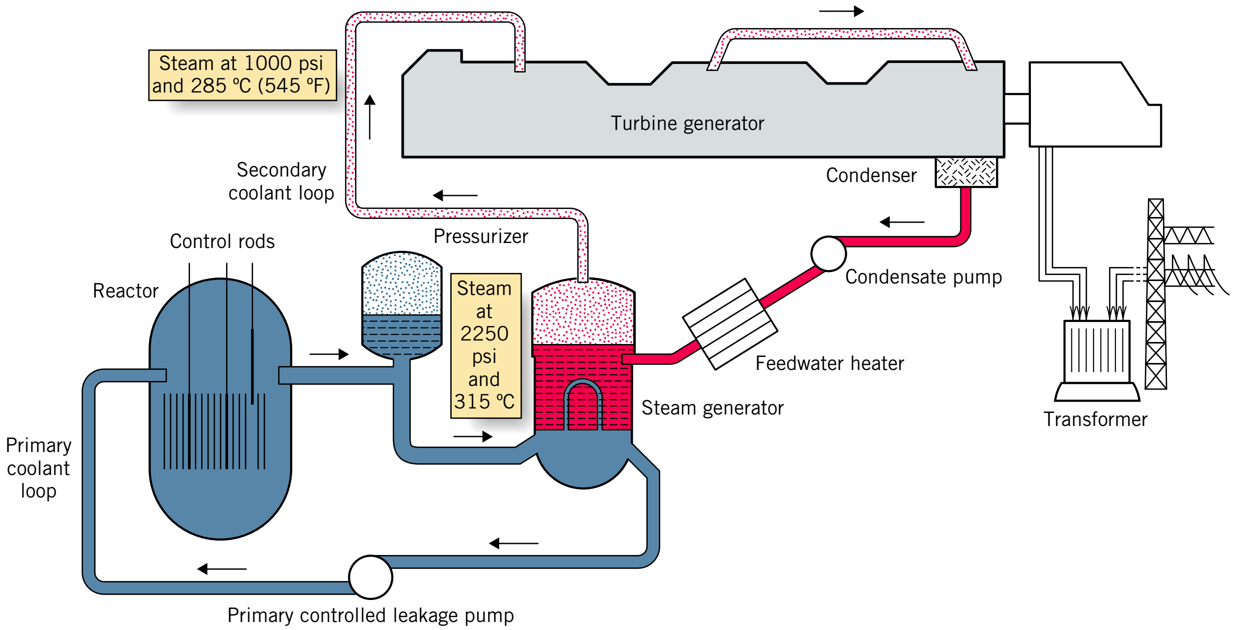

Figure 21.15 | **Pressurized water reactor, the type used in most of the nuclear power plants in the United States.** Water in the primary coolant loop is pumped around and through the fuel elements in the core, and it carries away the heat of the nuclear chain reactions. The hot water delivers its heat to the cooler water in the secondary coolant loop, where steam is generated to drive the turbines. *(Drawing from WASH-1261, U. S. Atomic Energy Commission, 1973.)*

The hot water in the primary loop transfers thermal energy to the secondary loop at the steam generator (Figure 21.15). This makes steam at high temperature and pressure, which is piped to the turbine. As the steam drives the turbine, the steam pressure drops. The condenser at the end of the turbine, cooled by water circulating from a river or lake or from huge cooling towers, forces a maximum pressure drop within the turbine by condensing the steam to liquid water. The returned water is then recycled to high-pressure steam. (In the boiling water reactor, there is only one coolant loop. The water heated in the reactor itself is changed to the steam that drives the turbine.)

Radioactive Waste

Radioactive wastes from nuclear power plants occur as gases, liquids, and solids. The gases are mostly radionuclides of krypton and xenon, but with the exception of xenon-85 ($t_{1/2} = 10.4$ years), the gases have short half-lives and decay quickly. During decay, they must be contained, and this is one function of the cladding. Other dangerous radionuclides produced by fission include iodine-131, strontium-90, and cesium-137.

■ Cesium-137 has a half-life of 30 years; that of strontium-90 is 28.1 years. Both are beta emitters.

Iodine-131 must be contained because the human thyroid gland concentrates iodide ion to make the hormone thyroxine. Once the isotope is in the gland, beta radiation from iodine-131 could cause harm, possibly thyroid cancer and possibly impaired thyroid function. An effective countermeasure to iodine-131 poisoning is to take doses of ordinary iodine (as sodium iodide). Statistically, this increases the likelihood that the thyroid will take up stable iodide ion rather than the unstable anion of iodine-131.

Cesium-137 and strontium-90 also pose problems to humans. Cesium is in Group 1A together with sodium, so radiating cesium-137 cations travel to some of the same places in the body where sodium ions go. Strontium is in Group 2A with calcium, so strontium-90 cations can replace calcium ions in bone tissue, sending radiation into bone marrow and possibly causing leukemia. The half-lives of cesium-137 and strontium-90, however, are relatively short.

Some radionuclides in wastes are so long-lived that solid reactor wastes must be kept away from all human contact for dozens of centuries, longer than any nation has ever yet endured. Probably the most intensively studied procedure for making solid radioactive wastes secure is to convert them to glasslike or rocklike solids, and bury them deeply within a rock stratum or in a mountain believed to be stable on the geological time scale with respect to earthquakes or volcanoes. Finding a location for such a site has been the subject of much scientific and political debate.

Nuclear Fusion

In Section 21.2 we mentioned that joining, or *fusing*, two light nuclei that lie to the left of the peak in the nuclear binding energy curve in Figure 21.1 leads to a net increase in nuclear binding energy and a corresponding release of energy. The process is called *nuclear fusion,* and the amount of energy released is considerably greater than in fission. Harnessing this energy for peaceful purposes is still a long way off, however, because many immensely difficult scientific and engineering problems still remain to be solved.

Deuterium, ${}^{2}_{1}\mathrm{H}$, an isotope of hydrogen, is a key fuel in all approaches to fusion. It is naturally present as 0.015% of all hydrogen atoms, including those in water. Despite this low percentage, the earth has so much water that the supply of deuterium is virtually limitless.

The fusion reaction most likely to be used in a successful fusion reactor involves the fusion of deuterium and tritium, ${}^{3}_{1}\mathrm{H}$, another isotope of hydrogen:

$$\underset{\text{deuterium}}{{}^{2}_{1}\mathrm{H}} + \underset{\text{tritium}}{{}^{3}_{1}\mathrm{H}} \longrightarrow \underset{\text{helium}}{{}^{4}_{2}\mathrm{He}} + \underset{\text{neutron}}{{}^{1}_{0}\mathrm{n}} + 17.6\ \mathrm{MeV}$$

This corresponds to an energy yield of 2.82×10^{-12} J for each atom of helium formed, or 1.70×10^{9} kJ per mole of He formed. One problem with this reaction is that tritium is radioactive with a relatively short half-life, so it doesn't occur naturally. It can be made in several ways, however, from lithium or even deuterium via other nuclear reactions.

Comparing fission and fusion on a mass basis, the fission of one kilogram of ${}^{235}\mathrm{U}$ yields approximately 8×10^{13} J, whereas forming one kilogram of ${}^{4}\mathrm{He}$ by the preceding fusion reaction yields 4.2×10^{14} J. Therefore, on a mass basis, fusion yields more than five times as much energy as fission. The potential energy yield from fusion is so great that the deuterium in just 0.005 cubic kilometers of ocean would supply the energy needs of the United States for one year.

Thermonuclear Fusion

The central scientific problem with fusion is to get the fusing nuclei close enough for a long enough time that the nuclear strong force (of attraction) can overcome the electrostatic force (of repulsion). As we learned in Section 21.3, the strong force acts over a much shorter range than the electrostatic force. Two nuclei on a collision course, therefore, repel each other virtually until they touch and get into the range of the strong force. The kinetic energies of two approaching nuclei must therefore be very substantial if they are to overcome this electrostatic barrier. Achieving such energies, moreover, must be accomplished by large numbers of nuclei all at once in batch after batch if there is to be any practical generation of electrical power by nuclear fusion. Relatively isolated fusion events achieved in huge accelerators will not do. The only practical way to give batch quantities of nuclei enough energy is to transfer *thermal* energy to them, and so the overall process is called *thermonuclear fusion.* Temperatures required to provide such thermal energy are very high—namely, more than 100 million degrees Celsius!

The atoms whose nuclei we want to fuse must first be stripped of their electrons. Thus, a high energy cost is exacted from the start but, overall, the energy yield will more than pay for it. The product is an electrically neutral, gaseous mixture of nuclei and unattached electrons called a **plasma**. The plasma must then be made so dense that like-charged nuclei are within 2 fm (2×10^{-15} m) of each other, meaning a plasma density of roughly 200 g cm^{-3} as compared with 200 mg cm^{-3} under ordinary conditions. To achieve this, the plasma must be confined at a pressure of several billion atmospheres long enough for the separate nuclei to fuse. The temperature needed is several times the temperature at the center of our sun.

Although practical peaceful uses for thermonuclear fusion are still in the distant future, military applications have been around for over 50 years. Thermonuclear fusion is the source of the energy released in the explosion of a hydrogen bomb. The energy needed to trigger the fusion is provided by the explosion of a fission bomb based on either uranium or plutonium.

■ The interior of the sun is at a temperature of approximately 15 million kelvins (15 MK).

Fusion in the Sun and Stars

Nature has used thermonuclear fusion since the origin of the universe as the source of energy in stars, where high temperatures (about 15 megakelvins) and huge gravity provide the kinetic energy and high density needed to initiate fusion reactions. The chief process in solar-mass stars is called the proton–proton cycle.

The Proton–Proton Cycle

$$\begin{array}{lrcl}
 & 2({}^{1}_{1}\mathrm{H} + {}^{1}_{1}\mathrm{H}) & \longrightarrow & 2\ {}^{2}_{1}\mathrm{H} + 2\ {}^{0}_{1}e + 2\ \nu \\
 & 2({}^{1}_{1}\mathrm{H} + {}^{2}_{1}\mathrm{H}) & \longrightarrow & 2\ {}^{3}_{2}\mathrm{He} + 2\gamma \\
 & {}^{3}_{2}\mathrm{He} + {}^{3}_{2}\mathrm{He} & \longrightarrow & {}^{4}_{2}\mathrm{He} + {}^{1}_{1}\mathrm{H} + {}^{1}_{1}\mathrm{H} \\
\hline
\text{Net:} & 4\ {}^{1}_{1}\mathrm{H} & \longrightarrow & {}^{4}_{2}\mathrm{He} + 2\ {}^{0}_{1}e + 2\ \nu + 2\gamma
\end{array}$$

The positrons produced combine with electrons in the plasma, annihilate each other, and generate additional energy and gamma radiation. Virtually all the neutrinos escape the sun and move into the solar system (and beyond), carrying with them a little less than 2% of the energy generated by the cycle. Not counting the energy of the neutrinos, each operation of one cycle generates 26.2 MeV or 4.20×10^{-12} J, which is equivalent to 2.53×10^{12} J per *mole* of alpha particles produced. This is the source of the solar energy radiated throughout our system, which can continue in this way for another 5 billion years.

■ Even at a temperature of 15 megakelvins, the rate of energy production per cubic centimeter by fusion in the sun is only about 10^{-4} J s^{-1} cm^{-3}. (That's thousands of times less than the rate at which a human body generates heat!) But because the sun has such a large volume, the *total* rate of energy production is enormous.

Analyzing and Solving Multi-Concept Problems

Another element formed in the sun is beryllium-7. It has a mass of 7.016928 u. Combustion of how much oil, in kg, would release the same amount of energy as the amount of energy released by the formation of 1.00 kg of ^{7}Be? Since oil is made up of many different compounds, assume that this oil is $C_{20}H_{42}$, which has a ΔH°_{f} of −2330 kJ/mol.

■ **Analysis** We are being asked to compare two reactions and the energy that they produce. The first reaction is a nuclear reaction, and the amount of energy released in this reaction will need to be used to calculate the amount of material in the second, combustion reaction. The solution will be divided into four parts: (1) for the first reaction, we will determine the binding energy for ^{7}Be, and (2) then we will determine the amount of energy released in that process for 1.00 kg of ^{7}Be. We will then turn our attention to the oil and do the following: (3) find the heat of combustion for $C_{20}H_{42}$ and then (4) the amount of $C_{20}H_{42}$ that gives off the same amount of heat as the ^{7}Be. Alternatively, we could have first calculated the heat of combustion of $C_{20}H_{42}$ and then done the calculations with the ^{7}Be, and finally compared the two to determine the amount of $C_{20}H_{42}$ required.

PART 1

■ **Assembling the Tools** We will find the nuclear binding energy of ^{7}Be from the mass defect using the rest mass of the proton, neutron, and ^{7}Be nucleus.

■ **Solution** We start with the makeup of ^{7}Be and the masses of protons and neutrons. There are four protons and three neutrons in ^{7}Be, and the mass of a proton is 1.007276467 u and the mass of a neutron is 1.0086649156 u.

$$\begin{aligned}\text{For 4 protons: } 4 \times 1.007276467\ \text{u} &= 4.029105868\ \text{u}\\ \text{For 3 neutrons: } 3 \times 1.008664916\ \text{u} &= \underline{3.025994748\ \text{u}}\\ \text{Total rest mass of nucleons in } {}^7\text{Be} &= 7.055100616\ \text{u}\end{aligned}$$

The mass defect is calculated from the difference between the mass of the nucleons and the mass of the ^{7}Be nucleus:

$$\underset{\text{mass of the 7 nucleons}}{7.055100616\ \text{u}} - \underset{\text{mass of nuclei}}{7.016928\ \text{u}} = \underset{\text{mass defect}}{0.038173\ \text{u}}$$

PART 2

Assembling the Tools Now that we have the mass defect, we can apply the Einstein equation to calculate the amount of energy equivalent to the mass lost,

$$E = mc^2$$

in which the m is the mass lost, 0.038173 u, and c is the speed of light, $2.9979 \times 10^8\ \text{m s}^{-1}$. After we calculate the energy lost for one atom, we can then calculate it for 1.00 kg of ^{7}Be by converting from one atom to one mole to mass using Avogadro's number and the molar mass of ^{7}Be, respectively.

Solution For Part 2, the first step is using the Einstein equation to calculate the amount of energy released upon the formation of one ^{7}Be nucleus:

$$\begin{aligned}E &= mc^2\\ E &= (0.038173\ \cancel{\text{u}}) \times \frac{1.660654 \times 10^{-27}\ \text{kg}}{1\ \cancel{\text{u}}} \times (2.9979 \times 10^8\ \text{m s}^{-1})^2\\ &= 5.6973 \times 10^{-12}\ \text{kg m}^2\ \text{s}^{-2}\\ &= 5.6973 \times 10^{-12}\ \text{J}\end{aligned}$$

Now we need to calculate the amount of energy released for 1.00 kg of ^{7} Be:

$$\begin{aligned}E &= 1.00\ \cancel{\text{kg}\ {}^7\text{Be}} \times \frac{1000\ \cancel{\text{g}\ {}^7\text{Be}}}{1\ \cancel{\text{kg}\ {}^7\text{Be}}} \times \frac{1\ \cancel{\text{mol}\ {}^7\text{Be}}}{7.016928\ \cancel{\text{g}\ {}^7\text{Be}}} \times \frac{6.022 \times 10^{23}\ \cancel{\text{atoms}\ {}^7\text{Be}}}{1\ \cancel{\text{mol}\ {}^7\text{Be}}} \times \frac{5.6973 \times 10^{-12}\ \text{J}}{1\ \cancel{\text{atom}\ {}^7\text{Be}}}\\ &= 4.89 \times 10^{14}\ \text{J}\\ &= 4.89 \times 10^{11}\ \text{kJ}\end{aligned}$$

This is the amount of energy released by the formation of 1.00 kg of ^{7} Be.

PART 3

Assembling the Tools Now, we need to find out how much oil will release this much energy upon combustion. We need to start by determining the balanced chemical equation for this process,

$$2\text{C}_{20}\text{H}_{42}(l) + 61\text{O}_2(g) \longrightarrow 40\text{CO}_2(g) + 42\text{H}_2\text{O}(g)$$

Then we must calculate the heat released for this reaction using Hess's law:

$$\Delta H^\circ_{\text{reaction}} = \begin{bmatrix}\text{sum of } \Delta H^\circ_{\text{f}} \text{ of all}\\ \text{of the products}\end{bmatrix} - \begin{bmatrix}\text{sum of } \Delta H^\circ_{\text{f}} \text{ of all}\\ \text{of the reactants}\end{bmatrix}$$

Solution We have the balanced chemical equation and the equation for Hess's law, so we can set up the equation:

$$\begin{aligned}\Delta H^\circ = {} & [40\ \text{mol CO}_2(g) \times \Delta H^\circ_{\text{f CO}_2(g)} + 42\ \text{mol H}_2\text{O}(l) \times \Delta H^\circ_{\text{f H}_2\text{O}(l)}]\\ & - [2\ \text{mol C}_{20}\text{H}_{42}(l) \times \Delta H^\circ_{\text{f C}_{20}\text{H}_{42}(l)}]\end{aligned}$$

From Table C.1 in Appendix C, we can find the enthalpies of formation for $CO_2(g)$ and $H_2O(g)$, and use it in the equation:

$$\Delta H^\circ = \left[\left(40\ \cancel{\text{mol CO}_2(g)}\right) \times \left(\frac{-393.5\ \text{kJ}}{\cancel{\text{mol CO}_2(g)}}\right) + 42\ \cancel{\text{mol H}_2\text{O}} \times \left(\frac{-241.8\ \text{kJ}}{\cancel{\text{mol H}_2\text{O}}}\right)\right]$$

$$- \left[2\ \cancel{\text{mol C}_{20}\text{H}_{42}} \times \left(\frac{-2330\ \text{kJ}}{\cancel{\text{mol C}_{20}\text{H}_{42}}}\right)\right]$$

$$\Delta H^\circ = -21{,}240\ \text{kJ}$$

This is the amount of heat given off by the combustion of two moles of $C_{20}H_{42}$.

PART 4

Assembling the Tools For the last step in this problem, we have to find out how many kilograms of $C_{20}H_{42}$ will give off 4.89×10^{11} kJ of energy. We have 21,240 kJ of energy given off by the combustion of 2 mol of $C_{20}H_{42}$, so we will have to find the number of moles of $C_{20}H_{42}$ that will give off 4.89×10^{11} kJ, and convert the moles to kilograms.

Solution For this step, we can find the number of moles of $C_{20}H_{42}$ that will give off 4.89×10^{11} kJ:

$$\text{mol C}_{20}\text{H}_{42} = 4.89 \times 10^{11}\ \cancel{\text{kJ}} \times \frac{2\ \text{mol C}_{20}\text{H}_{42}}{2.124 \times 10^{4}\ \cancel{\text{kJ}}}$$

$$= 4.61 \times 10^{7}\ \text{mol}$$

Now we can calculate the mass of 4.61×10^7 mol $C_{20}H_{42}$ using the molar mass of $C_{20}H_{42}$:

$$\text{kg C}_{20}\text{H}_{42} = 4.61 \times 10^{7}\ \cancel{\text{mol C}_{20}\text{H}_{42}} \times \frac{282.6\ \cancel{\text{g C}_{20}\text{H}_{42}}}{1\ \cancel{\text{mol C}_{20}\text{H}_{42}}} \times \frac{1\ \text{kg C}_{20}\text{H}_{42}}{1000\ \cancel{\text{g C}_{20}\text{H}_{42}}}$$

$$= 1.30 \times 10^{7}\ \text{kg C}_{20}\text{H}_{42}$$

Are the Answers Reasonable? This is an incredibly large number. In order to check that our answer is correct, we should go through the reasoning again.

Summary

The Einstein Equation. Mass and energy are interconvertible, and the **Einstein equation**, $\Delta E = \Delta mc^2$ (where c is the speed of light), lets us calculate one from the other. The total of the energy in the universe and all of the mass calculated as an equivalent of energy is a constant, which is a statement of the **law of conservation of mass–energy**.

Nuclear Binding Energies. When a nucleus forms from its nucleons, some mass changes into energy. This amount of energy, the **nuclear binding energy**, would be required to break up the nucleus again. The higher the binding energy per nucleon, the more stable is the nucleus.

Radioactivity. The *electrostatic force* by which protons repel each other is overcome in the nucleus by the *nuclear strong force*. The ratio of neutrons to protons is a factor in nuclear stability. By radioactivity, the naturally occurring **radionuclides** adjust their neutron/proton ratios, lower their energies, and so become more stable by emitting **alpha** or **beta radiation**, and sometimes gamma radiation as well.

The loss of an **alpha particle** leaves a nucleus with four fewer units of mass number and two fewer of atomic number. Loss of a **beta particle** leaves a nucleus with the same mass number and an atomic number one unit higher. **Gamma radiation** lets a nucleus lose some energy without a change in mass or atomic number. Depending on the specific isotope, synthetic radionuclides emit alpha, beta, and gamma radiation. Some emit **positrons** (positive electrons, a form of **antimatter**) that produce gamma radiation by annihilation collisions with electrons. Other synthetic radionuclides decay by **electron capture** and emit X rays. Some radionuclides emit neutrons.

Nuclear equations are balanced when the mass numbers and atomic numbers on either side of the reaction arrow respectively balance. The energies of emission are usually described in **electron volts (eV)** or multiples thereof, where $1\ \text{eV} = 1.602 \times 10^{-19}\ \text{J}$.

A few very long-lived radionuclides in nature, like ^{238}U, are at the heads of **radioactive disintegration series**, which represent the successive decays of "daughter" radionuclides until a stable isotope forms.

Nuclear Stability. Stable nuclides generally fall within a curving band, called the **band of stability**, when all known nuclides are plotted according to their numbers of neutrons and protons. Radionuclides with neutron/proton ratios that are too high eject beta particles to adjust their ratios downward. Those with neutron/proton ratios that are too low generally emit positrons to change their ratios upward.

Isotopes whose nuclei consist of even numbers of both neutrons and protons are generally much more stable than those with odd numbers of both; this is the **odd–even rule**. Having all neutrons paired and all protons paired is energetically better (i.e., more stable) than having any nucleon unpaired. Isotopes with specific numbers of protons or neutrons, the **magic numbers** of 2, 8, 20, 28, 50, 82, and 126, are generally more stable than others.

Transmutation. When a bombardment particle—a proton, deuteron, alpha particle, or neutron—is captured, the resulting **compound nucleus** contains the energy of both the captured particle and its nucleons. The mode of decay of the compound nucleus is a function of its extra energy, not its extra mass. Many radionuclides have been made by these nuclear reactions, including all of the elements from 93 and higher.

Detecting and Measuring Radiation. Instruments to detect and measure **ionizing radiation—Geiger counters** or **scintillation counters**, for example—take advantage of the ability of radiation to generate ions in air or other matter. Such radiation can harm living tissue by producing **free radicals**.

The **curie (Ci)** and the **becquerel (Bq)**, the SI unit, describe how active a source is; $1\ \text{Ci} = 3.7 \times 10^{10}\ \text{Bq}$ where $1\ \text{Bq} = 1\ \text{disintegration/s}$.

The SI unit of absorbed dose, the **gray (Gy)**, is used to describe how much energy is absorbed by a unit mass of absorber; $1\ \text{Gy} = 1\ \text{J/kg}$. An older unit, the **rad**, is equal to 0.01 Gy.

The **sievert**, an SI unit, and the **rem**, an older unit, are used to compare doses absorbed by different tissues and caused by different kinds of radiation. A 600 rem whole-body dose is lethal.

The normal **background radiation** causes millirem exposures per year. Naturally occurring radon, cosmic rays, radionuclides in soil and stone building materials, medical X rays, and releases from nuclear tests or from nuclear power plants all contribute to this background.

Protection against radiation can be achieved by using dense shields (e.g., lead or thick concrete), by avoiding the overuse of radionuclides or X rays in medicine, and by taking advantage of the **inverse square law**. This law tells us that the intensity of radiation decreases with the square of the distance from its source.

Applications. **Tracer analysis** uses small amounts of a radionuclide, which can be detected using devices like the scintillation counter, to follow the path of chemical and biological processes. In **neutron activation analysis**, neutron bombardment causes some elements to become γ emitters. The radiation can be detected and measured, giving the identity and concentration of the activated elements. **Radiological dating** uses the known half-lives of naturally occurring radionuclides to date geological and archeological objects.

Fission and Fusion. Uranium-235, which occurs naturally, and plutonium-239, which can be made from uranium-238, are **fissile isotopes** that serve as the fuel in present-day reactors. When either isotope captures a thermal neutron, the isotope splits in one of several ways to give two smaller isotopes plus energy and more neutrons. The neutrons can generate additional fission events, enabling a nuclear chain reaction. If a critical mass of a fissile isotope is allowed to form, the **nuclear chain reaction** proceeds out of control, and the material detonates as an atomic bomb explosion. *Pressurized water reactors* are the most commonly used fission reactors for power generation, and have two loops of circulating fluids. In the primary loop, coolant circulates around the reactor core and absorbs the heat of fission. In the secondary loop, water accepts the heat and changes to high-pressure steam, which drives an electrical generator. One major problem with nuclear energy is the storage of radioactive wastes.

Thermonuclear fusion joins two light nuclei to form a heavier nucleus with the release of more energy than nuclear fission. A typical reaction combines $^{2}_{1}\text{H}$ and $^{3}_{1}\text{H}$ to give $^{4}_{2}\text{He}$ and a neutron. High temperatures and pressures are necessary to initiate the fusion reaction. In stars, gravity is able to contain the high temperature **plasma** and allow fusion to occur. In a hydrogen bomb, the reaction is initiated by a fission bomb. Scientific and engineering hurdles must still be overcome before fusion can be a viable peaceful energy source.

Tools for Problem Solving

The following tools were introduced in this chapter. Study them carefully so you can select the appropriate tool when needed.

The Einstein equation (page 978)

This equation, $\Delta E = \Delta m_0 c^2$ (or often just $E = mc^2$), is used when you have to relate an amount of mass to its equivalent in energy. Be careful of units in using the equation. To obtain joules, mass must be in units of kilograms and c must have units of m/s (because $1\ \text{J} = 1\ \text{kg m}^2\ \text{s}^{-2}$).

Balancing nuclear equations (page 982)

When you have to write and balance a nuclear equation, remember to apply the following two criteria:

1. The sums of the mass numbers on each side of the arrow must be equal.
2. The sums of the atomic numbers on each side must be the same.

The odd-even rule (page 990)

This rule allows you to judge and compare the likely stability of nuclei according to their numbers of protons and neutrons.

When the numbers of neutrons and protons in a nucleus are both even, the isotope is far more likely to be stable than when both numbers are odd.

Law of radioactive decay (page 995)

Use this law to relate the *activity* (in units of disintegrations per second, or Bq) to the *decay constant, k,* (a first-order rate constant) and the number of atoms of the radionuclide in the sample, N. The activity is a quantity that can be measured using a Geiger or scintillation counter:

$$\text{Activity} = -\frac{\Delta N}{\Delta t} = kN$$

Half-life of a radionuclide (page 995)

When you know the half-life of an isotope (which is available in tables), you can calculate the decay constant, k. This is useful when you need to apply the law of radioactive decay (see above).

$$t_{1/2} = \frac{\ln 2}{k}$$

Inverse square law (page 998)

This simple law lets you compute radiation intensity at various distances from a radioactive source. If the intensity, I_1, is known at distance d_1, then the intensity I_2 at distance d_2 can be calculated by

$$\frac{I_1}{I_2} = \frac{d_2^2}{d_1^2}$$

PLUS = *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com.** ILW = An Interactive Learningware solution is available for this problem. OH = An Office Hour video is available for this problem. Review Problems are presented in pairs separated by blue rules. Answers to problems whose numbers appear in blue are given in Appendix B. More challenging problems are marked with an asterisk *.

Review Questions

Conservation of Mass and Energy

21.1 In calculations involving chemical reactions, we can regard the law of conservation of mass as a law independent of the law of conservation of energy despite Einstein's union of the two. What fact(s) make(s) this possible?

21.2 How can we know that the speed of light is the absolute upper limit on the speed of any object?

21.3 State the following:

(a) law of conservation of mass–energy

(b) Einstein equation

21.4 What is the difference between the rest mass of a particle and the mass of a particle in motion? Why do we use the rest mass of the particle for most calculations?

Nuclear Binding Energy

21.5 Why isn't the sum of the masses of all nucleons in one nucleus equal to the mass of the actual nucleus?

21.6 Which element has the largest binding energy per nucleon? What happens to the nuclei when the binding energy is too small?

Radioactivity

21.7 When a substance is described as *radioactive*, what does that mean? Why is the term *radioactive decay* used to describe the phenomenon?

21.8 Three kinds of radiation make up nearly all of the radiation observed from naturally occurring radionuclides. What are they?

21.9 Give the composition of each of the following:

(a) alpha particle

(b) beta particle

(c) positron

(d) deuteron

21.10 Why is the penetrating ability of alpha radiation less than that of beta or gamma radiation?

21.11 With respect to their formation, how do gamma rays and X rays differ?

21.12 How does electron capture generate X rays?

21.13 For the process of beta emission, where does the electron originate? What particle emits the electron and what else is formed?

Band of Stability

21.14 What data are plotted and what criterion is used to identify the actual band in the band of stability?

21.15 Both barium-123 and barium-140 are radioactive, but which is more likely to have the *longer* half-life? Explain your answer.

21.16 Tin-112 is a stable nuclide but indium-112 is radioactive and has a very short half-life ($t_{1/2} = 14$ min). What does tin-112 have that indium-112 does not to account for this difference in stability?

21.17 Lanthanum-139 is a stable nuclide but lanthanum-140 is unstable ($t_{1/2} = 40$ hr). What rule of thumb concerning nuclear stability is involved?

21.18 As the atomic number increases, the neutron/proton ratio increases. What does this suggest is a factor in nuclear stability?

21.19 Radionuclides of high atomic number are far more likely to be alpha emitters than those of low atomic number. Offer an explanation for this phenomenon.

21.20 Although lead-164 has two magic numbers, 82 protons and 82 neutrons, this isotope is unknown. Lead-208, however, is known and stable. What problem accounts for the nonexistence of lead-164?

21.21 What decay particle is emitted from a nucleus of low to intermediate atomic number but a relatively high neutron/proton ratio? How does the emission of this particle benefit the nucleus?

21.22 What decay particle is emitted from a nucleus of low to intermediate atomic number but a relatively low neutron/proton ratio? How does the emission of this particle benefit the nucleus?

21.23 Does electron capture increase, decrease, or maintain the neutron/proton ratio in a nucleus? Are radionuclides above or below the band of stability more likely to undergo this change?

Transmutations

21.24 Compound nuclei form and then decay almost at once. What accounts for the instability of a compound nucleus?

21.25 What explains the existence of several decay modes for the compound nucleus aluminum-27?

21.26 Rutherford theorized that a compound nucleus forms when helium nuclei hit nitrogen-14 nuclei. If this compound nucleus decayed by the loss of a neutron instead of a proton, what would be the other product?

21.27 Why is it easier to use neutrons to form compound nuclei rather than alpha particles or other nuclei?

Measuring Radiations

21.28 What specific property of nuclear radiation is used by the Geiger counter?

21.29 Dangerous doses of radiation can actually involve very small quantities of energy. Explain.

21.30 What units, SI and common, are used to describe each of the following?

(a) the *activity* of a radioactive sample

(b) the *energy* of a particle or of a photon of radiation given off by a nucleus

(c) the amount of energy absorbed by a given mass by a dose of radiation

(d) dose equivalents for comparing biological effects

21.31 Explain the necessity in health sciences for the *sievert*.

21.32 Which is more dangerous: ingesting a radioactive compound with a short half-life or a radioactive compound with a long half-life if the compound can be eliminated from the body within a day?

Applications of Radionuclides

21.33 Why should a radionuclide used in diagnostic work have a short half-life? If the half-life is too short, what problem arises?

21.34 An alpha emitter is not used in diagnostic work. Why?

21.35 In general terms, explain how neutron activation analysis is used and how it works.

21.36 What is one assumption in the use of the uranium/lead ratio for dating ancient geologic formations?

***21.37** If a sample used for carbon-14 dating is contaminated by air, there is a potentially serious problem with the method. What is it?

21.38 List some of the kinds of radiation that make up our background radiation.

Nuclear Fission and Fusion

21.39 What do each of the following terms mean?

(a) thermal neutron

(b) nuclear fission

(c) fissile isotope

(d) nuclear fusion

21.40 Which fissile isotope occurs in nature?

21.41 What fact about the fission of uranium-235 makes it possible for a *chain reaction* to occur?

21.42 Explain in general terms why fission generates more neutrons than needed to initiate it.

21.43 Why would there be a *subcritical mass* of a fissile isotope? (Why isn't *any* mass of uranium-235 critical?)

21.44 What purpose is served by a *moderator* in a nuclear reactor?

21.45 Why is there no possibility of an atomic bomb explosion from a nuclear power plant?

21.46 Write the nuclear equation for the fusion reaction between deuterium and tritium. Why must tritium be synthesized for this reaction?

21.47 What obstacles make constructing a reactor for controlled nuclear fusion especially difficult?

Review Problems

Conservation of Mass and Energy

***21.48** Calculate the mass in kilograms of a 1.00 kg object when its velocity, relative to us, is **(a)** 3.00×10^7 m s^{-1}, **(b)** 2.90×10^8 m s^{-1}, and **(c)** 2.99×10^8 m s^{-1}. (Notice the progression of these numbers toward the velocity of light, 3.00×10^8 m s^{-1}.)

***21.49** Calculate the velocity, relative to us, in m s^{-1} of an object with a rest mass, m_0, of 1.000 kg when its mass, m, is **(a)** 1.005 kg, **(b)** 1.1 kg, and **(c)** 5.0 kg.

21.50 Calculate the mass equivalent in grams of 1.00 kJ of energy.

21.51 Calculate the energy equivalent in kJ of 1.00 g of mass.

OH **21.52** Calculate the amount of mass in nanograms that is changed into energy when one mole of liquid water forms by the combustion of hydrogen, all measurements being made at 1 atm and 25 °C. What percentage is this of the total mass of the reactants?

21.53 Show that the mass equivalent of the energy released by the complete combustion of 1 mol of methane (890 kJ) is 9.89 ng.

Nuclear Binding Energies

ILW OH **21.54** Calculate the binding energy in J/nucleon of the deuterium nucleus whose mass is 2.0135 u.

21.55 Calculate the binding energy in J/nucleon of the tritium nucleus whose mass is 3.01550 u.

21.56 What is the mass defect for copper-63 if the mass of the nucleus is 62.9529601 u? Calculate the binding energy for Cu-63.

21.57 What is the mass defect for americium-241 if the mass of the nucleus is 241.05682 u? Calculate the binding energy for Am-241.

Radioactivity

21.58 Complete the following nuclear equations by writing the symbols of the missing particles:

(a) $^{211}_{82}\text{Pb} \longrightarrow {}^{0}_{-1}e + \underline{\qquad}$

(b) $^{177}_{73}\text{Ta} \xrightarrow{\text{Electron capture}} \underline{\qquad}$

(c) $^{220}_{86}\text{Rn} \longrightarrow {}^{4}_{2}\text{He} + \underline{\qquad}$

(d) $^{19}_{10}\text{Ne} \longrightarrow {}^{0}_{1}e + \underline{\qquad}$

21.59 Write the symbols of the missing particles to complete the following nuclear equations:

(a) $^{245}_{96}\text{Cm} \longrightarrow {}^{4}_{2}\text{He} + \underline{\qquad}$

(b) $^{146}_{56}\text{Ba} \longrightarrow {}^{0}_{-1}e + \underline{\qquad}$

(c) $^{58}_{29}\text{Cu} \longrightarrow {}^{0}_{1}e + \underline{\qquad}$

(d) $^{68}_{32}\text{Ge} \xrightarrow{\text{Electron capture}} \underline{\qquad}$

OH 21.60 Write a balanced nuclear equation for each of the following changes:

(a) alpha emission from plutonium-242

(b) beta emission from magnesium-28

(c) positron emission from silicon-26

(d) electron capture by argon-37

OH 21.61 Write the balanced nuclear equation for each of the following nuclear reactions:

(a) electron capture by iron-55

(b) beta emission by potassium-42

(c) positron emission by ruthenium-93

(d) alpha emission by californium-251

21.62 Write the symbols, including the atomic and mass numbers, for the radionuclides that would give each of the following products:

(a) fermium-257 by alpha emission

(b) bismuth-211 by beta emission

(c) neodymium-141 by positron emission

(d) tantalum-179 by electron capture

21.63 Each of the following nuclides forms by the decay mode described. Write the symbols of the parents, giving both atomic and mass numbers:

(a) rubidium-80 formed by electron capture

(b) antimony-121 formed by beta emission

(c) chromium-50 formed by positron emission

(d) californium-253 formed by alpha emission

21.64 Krypton-87 decays to krypton-86. What other particle forms?

21.65 Write the symbol of the nuclide that forms from cobalt-58 when it decays by electron capture.

Band of Stability

OH 21.66 If an atom of potassium-38 had the option of decaying by positron emission or beta emission, which route would it likely take, and why? Write the balanced nuclear equation.

21.67 Suppose that an atom of argon-37 could decay by either beta emission or electron capture. Which route would it likely take, and why? Write the balanced nuclear equation.

21.68 What is the most probable decay process for polonium-209? Write the balanced nuclear equation.

21.69 What is the most probable decay process for silicon-32? Write the balanced nuclear equation.

21.70 If we begin with 3.00 mg of iodine-131 ($t_{1/2} = 8.07$ hr), how much remains after six half-life periods?

21.71 A sample of technetium-99*m* with a mass of 9.00 ng will have decayed to how much of this radionuclide after four half-life periods (about 1 day)?

Transmutations

21.72 When vanadium-51 captures a deuteron ($^{2}_{1}\text{H}$), what compound nucleus forms? (Write its symbol.) This particle expels a proton ($^{1}_{1}p$). Write the balanced nuclear equation for the overall change from vanadium-51.

21.73 The alpha-particle bombardment of fluorine-19 generates sodium-22 and neutrons. Write the balanced nuclear equation, including the intermediate compound nucleus.

OH 21.74 Gamma-ray bombardment of bromine-81 causes a transmutation in which a neutron is one product. Write the symbol of the other product.

21.75 Neutron bombardment of cadmium-115 results in neutron capture and the release of gamma radiation. Write the balanced nuclear equation.

21.76 When manganese-55 is bombarded by protons, each ^{55}Mn nucleus releases a neutron. What else forms? Write the balanced nuclear equation.

21.77 Which nuclide forms when sodium-23 is bombarded by alpha particles and the compound nucleus emits a gamma ray photon?

21.78 The nuclei of which isotope of zinc would be needed as bombardment particles to make nuclei of element 112 from lead-208 if the intermediate compound nucleus loses a neutron?

21.79 Write the symbol of the nuclide whose nuclei would be the target for bombardment by nickel-64 nuclei to produce nuclei of $^{272}_{111}\text{Rg}$ after the intermediate compound nucleus loses a neutron.

Measuring Radiations

21.80 Suppose that a radiologist who is 2.0 m from a small, unshielded source of radiation receives 2.8 units of radiation. To reduce the exposure to 0.28 units of radiation, to what distance from the source should the radiologist move?

21.81 By what percentage should a radiation specialist increase the distance from a small unshielded source to reduce the radiation intensity by 10.0%?

OH **21.82** If exposure from a distance of 1.60 m gave a worker a dose of 8.4 rem, how far should the worker move away from the source to reduce the dose to 0.50 rem for the same period?

21.83 During work with a radioactive source, a worker was told that he would receive 55 mrem at a distance of 4.0 m during 30 min of work. What would be the received dose if the worker moved closer, to 0.50 m, for the same period?

21.84 A sample giving 3.7×10^{10} disintegrations per second has what activity in Ci and in Bq?

21.85 A sample of a radioactive metal used in medicine has an activity of 3.5 mCi. What is its activity in Bq and how many disintegrations/s does it give?

21.86 Smoke detectors contain a small amount of americium-241, which has a half-life of 1.70×10^5 days. If the detector contains 0.20 mg of ^{241}Am, what is the activity, in becquerels? In microcuries?

21.87 Strontium-90 is a dangerous radioisotope present in fallout produced by nuclear weapons. ^{90}Sr has a half-life of 1.00×10^4 days. What is the activity of 1.00 g of ^{90}Sr, in becquerels? In microcuries?

21.88 Iodine-131 is a radioisotope present in radioactive fallout that targets the thyroid gland. If 1.00 mg of ^{131}I has an activity of 4.6×10^{12} Bq, what is the decay constant for ^{131}I? What is the half-life, in seconds?

21.89 A 10.0 mg sample of thallium-201 has an activity of 7.9×10^{13} Bq. What is the decay constant for ^{201}Tl? What is the half-life of ^{201}Tl, in seconds?

Applications of Radionuclides

OH **21.90** What percentage of cesium chloride made from cesium-137 (beta emitter, $t_{1/2} = 30.1$ y) remains after 150 y? What *chemical* product forms?

21.91 A sample of waste has a radioactivity, caused solely by strontium-90 (beta emitter, $t_{1/2} = 28.1$ yr), of $0.245\ \text{Ci g}^{-1}$. How many years will it take for its activity to decrease to $1.00 \times 10^{-6}\ \text{Ci g}^{-1}$?

21.92 A worker in a laboratory unknowingly became exposed to a sample of radio-labeled sodium iodide made from iodine-131 (beta emitter, $t_{1/2} = 8.07$ day). The mistake was realized 28.0 days after the accidental exposure, at which time the activity of the sample was 25.6×10^{-5} Ci/g. The safety officer needed to know how active the sample was at the time of the exposure. Calculate this value in Ci/g.

21.93 Technetium-99*m* (gamma emitter, $t_{1/2} = 6.02$ hr) is widely used for diagnosis in medicine. A sample prepared in the early morning for use that day had an activity of 4.52×10^{-6} Ci. What will its activity be at the end of the day—that is, after 8.00 hr?

21.94 A 0.500 g sample of rock was found to have 2.45×10^{-6} mol of potassium-40 ($t_{1/2} = 1.3 \times 10^9$ yr) and 2.45×10^{-6} mol of argon-40. How old was the rock? (What assumption is made about the origin of the argon-40?)

21.95 If a rock sample was found to contain 1.16×10^{-7} mol of argon-40, how much potassium-40 would also have to be present for the rock to be 1.3×10^9 years old?

21.96 A tree killed by being buried under volcanic ash was found to have a ratio of carbon-14 atoms to carbon-12 atoms of 4.8×10^{-14}. How long ago did the eruption occur?

21.97 A wooden door lintel from an excavated site in Mexico would be expected to have what ratio of carbon-14 to carbon-12 atoms if the lintel is 9.0×10^3 y old?

Nuclear Fission and Fusion

OH **21.98** Complete the following nuclear equation by supplying the symbol for the other product of the fission.

$$^{235}_{92}\text{U} + {}^{1}_{0}n \longrightarrow {}^{94}_{38}\text{Sr} + \underline{\qquad} + 2\,{}^{1}_{0}n$$

21.99 Both products of the fission in Problem 21.98 are unstable. According to Figures 21.8 and 21.9, what is the most likely way for each of them to decay: by alpha emission, beta emission, or positron emission? Explain. What are some of the possible fates of the extra neutrons produced by the fission shown in Problem 21.98?

Additional Exercises

21.100 The age of "young" groundwater can be determined by measuring the ratio of tritium to helium-3 in water. If "young" groundwater is no more than 40 years old, what percent of tritium will remain in water at 40 years? The amount of ^{3}He in the water is also measured at the same time as the amount of tritium. What would the sum of the moles of tritium and ^{3}He represent?

21.101 What is the balanced nuclear equation for each of the following changes?

(a) beta emission from aluminum-30

(b) alpha emission from einsteinium-252

(c) electron capture by molybdenum-93

(d) positron emission by phosphorus-28

*21.102 Calculate to five significant figures the binding energy in J/nucleon of the nucleus of an atom of iron-56. The observed mass of one *atom* is 55.9349 u. Which figure in this chapter lets us know that no isotope has a *larger* binding energy per nucleon?

21.103 Give the balanced nuclear equation for each of the following changes:

(a) positron emission by carbon-10

(b) alpha emission by curium-243

(c) electron capture by vanadium-49

(d) beta emission by oxygen-20

*21.104 If a positron is to be emitted spontaneously, how much more *mass* (as a minimum) must an *atom* of the parent have than an *atom* of the daughter nuclide? Explain.

*21.105 If a proton and an antiproton were to collide and produce two annihilation photons, what would the wavelength of the photons be, in meters? Which of the decimal multipliers in Table 2.4 (page 35) would be most appropriate for expressing this wavelength?

21.106 There is a gain in binding energy per nucleon when light nuclei fuse to form heavier nuclei. However, a tritium atom and a deuterium atom, in a mixture of these isotopes, does not spontaneously fuse to give helium (and energy). Explain why not.

21.107 ^{214}Bi decays to isotope *A* by alpha emission; *A* then decays to *B* by beta emission, which decays to *C* by another beta emission. Element *C* decays to *D* by still another beta emission, and *D* decays by alpha emission to a stable isotope, *E*. What is the proper symbol of element *E*? (Contributed by Prof. W. J. Wysochansky, Georgia Southern University.)

21.108 ^{15}O decays by positron emission with a half-life of 124 s. **(a)** Give the proper symbol of the product of the decay. **(b)** How much of a 750 mg sample of ^{15}O remains after 5.0 min of decay? (Contributed by Prof. W. J. Wysochansky, Georgia Southern University.)

21.109 Alpha decay of ^{238}U forms ^{234}Th. What kind of decay from ^{234}Th produces ^{234}Ac? (Contributed by Prof. Mark Benvenuto, University of Detroit–Mercy.)

21.110 A sample of rock was found to contain 2.07×10^{-5} mol of ^{40}K and 1.15×10^{-5} mol of ^{40}Ar. If we assume that all of the ^{40}Ar came from the decay of ^{40}K, what is the age of the rock in years? ($t_{1/2} = 1.3 \times 10^9$ years for ^{40}K)

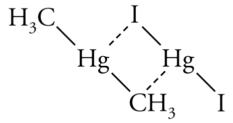
21.111 The ^{14}C content of an ancient piece of wood was found to be one-tenth of that in living trees. How many years old is this piece of wood? ($t_{1/2} = 5730$ years for ^{14}C.)

21.112 Dinitrogen trioxide, N_2O_3, is largely dissociated into NO and NO_2 in the gas phase where there exists the equilibrium,

$$N_2O_3 \rightleftharpoons NO + NO_2$$

In an effort to determine the structure of N_2O_3, a mixture of NO and $^*NO_2$ was prepared containing isotopically labeled N in the NO_2. After a period of time the mixture was analyzed and found to contain substantial amounts of both $^*NO$ and $^*NO_2$. Explain how this is consistent with the structure for N_2O_3 being ONONO.

21.113 The reaction, $(CH_3)_2Hg + HgI_2 \longrightarrow 2CH_3HgI$, is believed to occur through a transition state with the structure,



If this is so, what should be observed if CH_3HgI and $^*HgI_2$ are mixed, where the asterisk denotes a radioactive isotope of Hg? Explain your answer.

*21.114 A large, complex piece of apparatus has built into it a cooling system containing an unknown volume of cooling liquid. The volume of the coolant needs to be measured without draining the lines. To the coolant was added 10.0 mL of methanol whose molecules included atoms of ^{14}C and that had a specific activity (activity per gram) of 580 counts per minute per gram (cpm/g), determined using a Geiger counter. The coolant was permitted to circulate to assure complete mixing before a sample was withdrawn that was found to have a specific activity of 29 cpm/g. Calculate the volume of coolant in the system in milliliters. The density of methanol is 0.792 g/mL, and the density of the coolant is 0.884 g/mL.

21.115 Iodine-131 is used to treat Graves disease, a disease of the thyroid gland. The amount of ^{131}I used depends on the size of the gland. If the dose is 86 microcuries per gram of thyroid gland, how many grams of ^{131}I should be administered to a patient with a thyroid gland weighing 20 g? Assume all the iodine administered accumulates in the thyroid gland.

21.116 The fuel for a thermonuclear bomb (hydrogen bomb) is lithium deuteride, a salt composed of the ions $^6_3Li^+$ and $^2_1H^-$. Considering the nuclear reaction

$$^6_3Li + {}^1_1n \longrightarrow {}^4_2He + {}^3_1H$$

explain how a ^{235}U fission bomb could serve as a trigger for a fusion bomb. Write appropriate balanced nuclear equations.

21.117 In 2006, the synthesis of $^{294}_{118}$Uuo (an isotope of element 118) was reported to involve the bombardment of ^{245}Cf with ^{48}Ca. Write an equation for the nuclear reaction, being sure to include any other products of the reaction.

*21.118 Radon, a radioactive noble gas, is an environmental problem in some areas, where it can seep out of the ground and into homes. Exposure to radon-222, an α emitter with a half-life of 3.823 days, can increase the risk of lung cancer. At an exposure level of 4 pCi per liter (the level at which the EPA recommends action), the lifetime risk of death from lung cancer due to radon exposure is estimated to be 62 out of 1000 for current smokers, compared with 73 out of 10,000 for nonsmokers. If the air in a home was analyzed and found to have an activity of 4.1 pCi L^{-1}, how many atoms of ^{222}Rn are there per liter of air?

***21.119** The isotope ^{145}Pr decays by emission of beta particles with an energy of 1.80 MeV each. Suppose a person swallowed, by accident, 1.0 mg of Pr having a specific activity (activity per gram) of 140 Bq/g. What would be the absorbed dose from ^{145}Pr in units of Gy and rad over a period of 10 minutes? Assume all of the beta particles are absorbed by the person's body.

21.120 Why is the isotope ^{36}Cl radioactive while ^{35}Cl and ^{37}Cl are not? The isotope decays by beta emission, what isotope is formed? Write the nuclear equation that shows the process.

Multi-Concept Questions

***21.121** A complex ion of chromium(III) with oxalate ion was prepared from ^{51}Cr-labeled $K_2Cr_2O_7$, having a specific activity of 843 cpm/g (counts per minute per gram), and ^{14}C-labeled oxalic acid, $H_2C_2O_4$, having an specific activity of 345 cpm/g. Chromium-51 decays by electron capture with the emission of gamma radiation, whereas ^{14}C is a pure beta emitter. Because of the characteristics of the beta and gamma detectors, each of these isotopes may be counted independently. A sample of the complex ion was observed to give a gamma count of 165 cpm and a beta count of 83 cpm. From these data, determine the number of oxalate ions bound to each Cr(III) in the complex ion. (*Hint*: For the starting materials calculate the cpm per mole of Cr and oxalate, respectively.)

21.122 Iridium-192, a beta emitter, is used in medicine to treat certain cancers. The ^{192}Ir is used as a wire and inserted near the tumor for a given amount of time and then removed. The ^{192}Ir wire is coated with pure platinum, and is sold by diameter and amount of radiation emitted. One type of wire sold is 140 mm long, has a linear apparent activity of 30–130 MBq/cm, an active diameter (which is the iridium-192) of 0.1 mm, and an outer diameter (the platinum) of 0.3 mm. How much ^{192}Ir is in the wire if the apparent activity is 30 MBq/cm? If the wire is placed in the tumor for 50 hours, how much radiation is absorbed by the tumor? The wire is shipped in lead tubes—why?

Exercises in Critical Thinking

21.123 A silver wire coated with nonradioactive silver chloride is placed into a solution of sodium chloride that is labeled with radioactive ^{36}Cl. After a while, the AgCl was analyzed and found to contain some ^{36}Cl. How do you interpret the results of this experiment?

21.124 Suppose you were given a piece of cotton cloth and told that it was believed to be 2000 years old. You performed a carbon dating test on a tiny piece of the cloth and your data indicated that it was only 800 years old. If the cloth really was 2000 years old, what factors might account for your results?

21.125 In 2006, the former Soviet spy Alexander Litvinenko was poisoned by the polonium isotope ^{210}Po. He died 23 days after ingesting the isotope, which is an alpha emitter. Find data on the Internet to answer the following: Assuming Litvinenko was fed 1 μg of ^{210}Po and that it became uniformly distributed through the cells in his body, how many atoms of ^{210}Po made their way into each cell in his body? (Assume his body contained the average number of cells found in an adult human.) Also, calculate the number of cells affected by the radiation each second, being sure to take into account an estimate of the average number of cells affected by an alpha particle emitted by a ^{210}Po nucleus.

21.126 What would be the formula of the simplest hydrogen compound of element 116? Would a solution of this compound in water be acidic, basic, or neutral? Explain your reasoning.

21.127 Astatine is a halogen. Its most stable isotope, ^{110}At, has a half-life of only 8.3 hours, and only very minute amounts of the element are ever available for study ($<$0.001 μg). This amount is so small as to be virtually invisible. Describe experiments you might perform that would tell you whether the silver salt of astatine, AgAt, is insoluble in water.

22 Metal Complexes

Chapter Outline

22.1 | Complex Ions

22.2 | Metal Complex Nomenclature

22.3 | Coordination Number and Structure

22.4 | Isomers of Metal Complexes

22.5 | Bonding in Metal Complexes

22.6 | Biological Functions of Metal Ions

The horseshoe crab—considered a living fossil—has blue blood, while humans have red blood. The color of the blood is influenced by the metal compounds that are found in blood. The blood of horseshoe crabs contains hemocyanin, a copper-containing protein that transports oxygen, whereas human blood uses hemoglobin, which is iron based, to carry oxygen. In this chapter, we will look at how metals are bonded to other ions and molecules and how the color of the compounds are affected by the metal and its bonds. Rick Poley/Visuals Unlimited

This Chapter in Context

In previous chapters you learned many of the concepts that chemists have used to develop an understanding of how the elements react with each other and the kinds of compounds they produce. For example, in our discussions of chemical kinetics, you learned how various factors affect the rates of reactions, and in our study of thermodynamics you learned how enthalpy and entropy changes affect the possibility of observing chemical changes. Our focus, however, was primarily on the concepts themselves, with examples of chemical behavior being used to reinforce and justify them. With all of these concepts available to us now, we will direct our emphasis in the opposite direction and examine some of the physical and chemical properties of the compounds of metals.

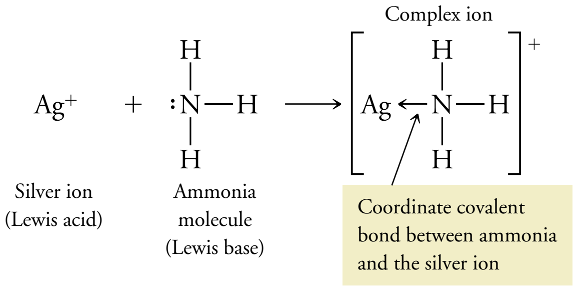
This chapter is devoted to an in-depth look at complex ions of metals, a topic first introduced in Chapter 18. These substances, which have applications from food preservatives to catalyzing biochemical reactions, have a variety of structures and colors. We will study the kinds of substances that combine with metals to form complexes, how complexes are named, and how the electronic structures and colors of complexes can be explained.

22.1 | Complex Ions

In Section 18.4 (page 855), we introduced you to **complex ions** (or more simply, **complexes**) of metals. Recall that these are substances formed when molecules or anions become bonded covalently to metal ions to form more complex species. Two examples that were given were the pale blue $Cu(H_2O)_6{}^{2+}$ ion and the deep blue $Cu(NH_3)_4{}^{2+}$ ion. In Chapter 18, we discussed how the formation of complex ions can affect the solubilities of salts, but the importance of these substances reaches far beyond solubility equilibria. The number of complex ions formed by metals, especially the transition metals, is enormous, and the study of the properties, reactions, structures, and bonding in complexes like $Cu(NH_3)_4{}^{2+}$ has become an important specialty within chemistry. The study of metal complexes even extends into biochemistry—for example, the metal ions in the horseshoe crab pictured in the chapter opener. This is because, ultimately, nearly all of the metals in our bodies become bound in complexes in order to perform their biochemical functions.

Before we proceed further, let's consider some of the basic terminology we will use in our discussions. The molecules or ions that become attached to a metal ion [e.g., the NH_3 molecules in $Cu(NH_3)_4{}^{2+}$] are called **ligands.** Ligands are either neutral molecules or anions that contain one or more atoms with at least one unshared electron pair that can be donated to the metal ion in the formation of a metal–ligand bond. The reaction of a ligand with a metal ion is therefore a Lewis acid–base reaction in which the ligand is the Lewis base (the electron pair donor) and the metal ion is the Lewis acid (the electron pair acceptor).

■ Recall that a coordinate covalent bond is one in which both of the shared electrons originate on the same atom. Once formed, of course, a coordinate covalent bond is just like any other covalent bond.



Complex ion
Ag⁺
+
:N—H
H

Ag ← N—H
+
Silver ion (Lewis acid)
Ammonia molecule (Lewis base)
Coordinate covalent bond between ammonia and the silver ion

A ligand atom that donates an electron pair to the metal is said to be a **donor atom** and the metal is the **acceptor**. Thus, in the preceding $AgNH_3^+$ example, the nitrogen of the ammonia molecule is the donor atom and the silver ion is the acceptor. Because of the way the metal–ligand bond is formed, it can be considered to be a covalent bond, and compounds that contain metal complexes are often called **coordination compounds**. The complexes themselves are sometimes referred to as **coordination complexes.**

Types of Ligands

Ligands, whether they are anions or neutral molecules, are *Lewis bases.* As a result, they contain at least one atom with one or more lone pairs (unshared pairs) of electrons.

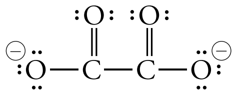
Anions that serve as ligands include many simple monatomic ions, such as the halide ions (F^-, Cl^-, Br^-, and I^-) and the sulfide ion (S^{2-}). Common polyatomic anions that are ligands are nitrite ion (NO_2^-), cyanide ion (CN^-), hydroxide ion (OH^-), thiocyanate ion (SCN^-), and thiosulfate ion ($S_2O_3^{2-}$). (This is really only a small sampling, not a complete list.)

The most common neutral molecule that serves as a ligand is water, and most of the reactions of metal ions in aqueous solutions are actually reactions of their complex ions—ions in which the metal is attached to some number of water molecules. Copper(II) ions,[1] for example, form the complex ion $Cu(H_2O)_6^{2+}$, and cobalt(II) also combines with water molecules to form $Co(H_2O)_6^{2+}$. Another common neutral ligand is ammonia, NH_3, which has one lone pair of electrons on the nitrogen atom. If ammonia is added to an aqueous solution containing the $Ni(H_2O)_6^{2+}$ ion, for example, the color changes dramatically from green to blue as ammonia molecules displace water molecules (see Figure 22.1):

$$\underset{\text{(green)}}{Ni(H_2O)_6^{2+}(aq)} + 5NH_3(aq) \longrightarrow \underset{\text{(blue)}}{Ni(NH_3)_5(H_2O)^{2+}(aq)} + 5H_2O$$

Each of the ligands that we have discussed so far is able to use just one atom to attach itself to a metal ion. Such ligands are called **monodentate ligands**, indicating that they have only "one tooth" with which to "bite" the metal ion.

There are also many ligands that have two or more donor atoms, and collectively they are referred to as **polydentate ligands**. The most common of these have two donor atoms, so they are called **bidentate ligands**. When they form complexes, *both* donor atoms become attached to the same metal ion. Oxalate ion and ethylenediamine (abbreviated *en* in writing the formula for a complex) are examples of bidentate ligands.



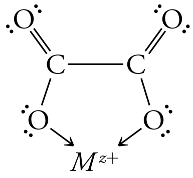
$$^{\ominus}\ddot{O}—\overset{\overset{\ddot{O}}{\|}}{C}—\overset{\overset{\ddot{O}}{\|}}{C}—\ddot{O}^{\ominus}$$

oxalate ion

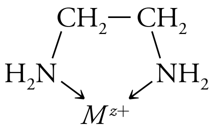
$$H_2\ddot{N}—CH_2—CH_2—\ddot{N}H_2$$

ethylenediamine, en

When these ligands become attached to a metal ion, the following ring structures are formed:



an oxalate complex



an ethylenediamine complex

---

[1] The formula $Cu(H_2O)_6^{2+}$ is actually an oversimplification. Copper(II) complexes in water usually have two water molecules loosely attached to the Cu^{2+} at a greater distance than the other four ligand atoms. Therefore, the copper(II) complex with water could also be written $Cu(H_2O)_4^{2+}$ to indicate the water molecules more strongly bound to the Cu^{2+} ion.

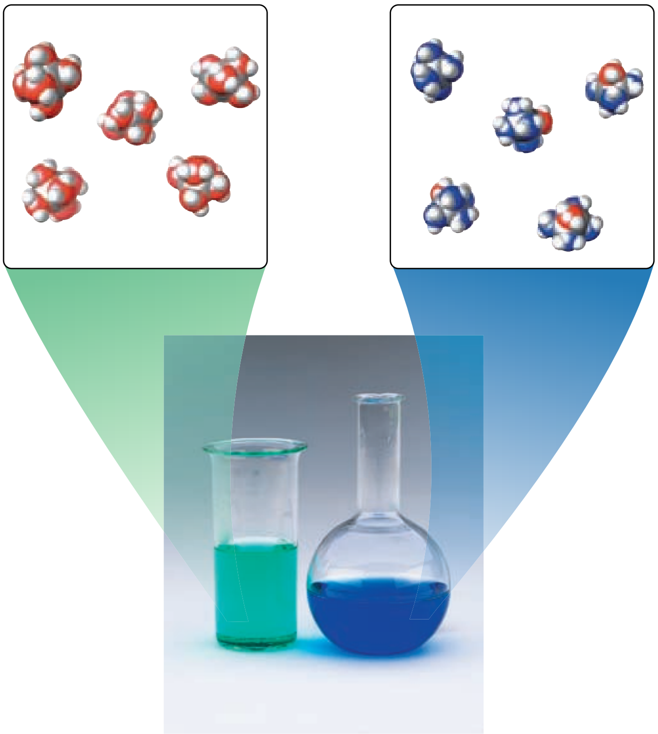


Figure 22.1 | **Complex ions of nickel.** (*Left*) A solution of nickel chloride, which contains the green $Ni(H_2O)_6^{2+}$ ion. (*Right*) Adding ammonia to the nickel chloride solution forms the blue $Ni(NH_3)_5(H_2O)^{2+}$ ion. *(Andy Washnik)*

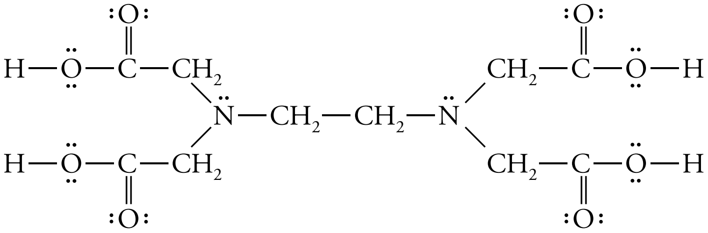
Complexes that contain such ring structures are called **chelates**.[2] Structures like these are important in "complex ion chemistry," as we shall see later in this chapter.

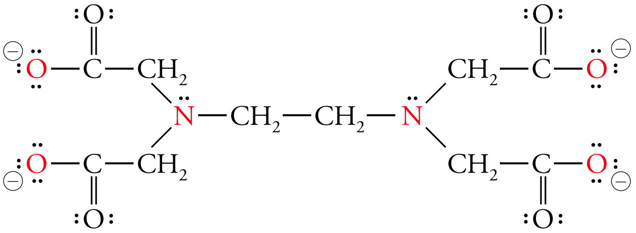
One of the most common polydentate ligands is a compound called ethylenediaminetetraacetate, mercifully abbreviated $EDTA^{4-}$ (or Y^{4-} by analytical chemists).

■ Sometimes the ligand $EDTA^{4-}$ is abbreviated using small letters—that is, $edta^{4-}$.

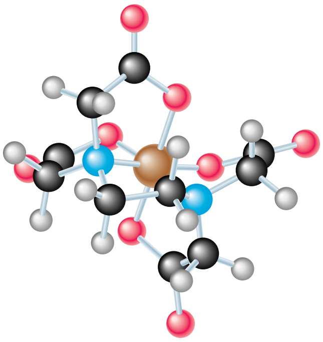


Ethylenediaminetetraacetic acid, H_4EDTA)

The H atoms attached to the oxygen atoms are easily removed as protons, which gives an anion with a charge of 4−. The structure of the anion, $EDTA^{4-}$, is as follows with the donor atoms in red:



$EDTA^{4-}$



The structure of an EDTA complex. The nitrogen atoms are blue, oxygen is red, carbon is black, and hydrogen is white. The metal ion is in the center of the complex bonded to the two nitrogens and four oxygens.

---

[2] The term *chelate* comes from the Greek *chele*, meaning claw. These bidentate ligands grasp the metal ions with two "claws" (donor atoms) somewhat like a crab holds its prey. (Who says scientists have no imagination?)

The $EDTA^{4-}$ ion has six donor atoms, and this permits it to wrap itself around a metal ion and form very stable complexes.

EDTA is a particularly useful and important ligand. It is relatively nontoxic, which allows it to be used in small amounts in foods to retard spoilage. If you look at the labels on bottles of salad dressings, for example, you often will find that one of the ingredients is $CaNa_2EDTA$ (calcium disodium EDTA). The $EDTA^{4-}$ available from this salt forms soluble complex ions with any traces of metal ions that might otherwise promote reactions of the salad oils with oxygen, and thereby lead to spoilage.

■ The *calcium* salt of EDTA is used because the $EDTA^{4-}$ ion would otherwise extract Ca^{2+} ions from bones, and that would be harmful.

Many shampoos contain Na_4EDTA to soften water. The $EDTA^{4-}$ binds to Ca^{2+}, Mg^{2+}, and Fe^{3+} ions, which removes them from the water and prevents them from interfering with the action of detergents in the shampoo. A similar application was described in the *Chemistry Outside the Classroom 18.1* on page 858.

EDTA is also sometimes added in small amounts to whole blood to prevent clotting. It ties up calcium ions, which the clotting process requires. EDTA has even been used as a treatment in cases of heavy metal poisoning because it can help remove the poisonous heavy metal ions, like Hg^{2+} and Pb^{2+}, from the body when they have been accidentally ingested.

Writing Formulas for Metal Complexes

When we write the formula for a complex, we utilize the following rules:

TOOLS

Rules for writing formulas for complexes

1. The symbol for the metal ion is always given first, followed by the ligands.
2. When more than one kind of ligand is present, anionic ligands are written first (in alphabetical order), followed by neutral ligands (also in alphabetical order).
3. The charge on the complex is the algebraic sum of the charge on the metal ion and the charges on the ligands.
4. The formula is placed inside of square brackets with the charge of the complex as a superscript outside the brackets, if it is not zero.

■ Square brackets here do not mean molar concentration. It is usually clear from the context of a discussion whether we intend the brackets to mean molarity or a chemical formula.

For example, the formula of the complex ion of Cu^{2+} and NH_3, which we mentioned earlier, was written $[Cu(NH_3)_4]^{2+}$ with the Cu first followed by the ligands. The charge on the complex is 2+ because the copper ion has a charge of 2+ and the ammonia molecules are neutral. Copper(II) ion also forms $[Cu(CN)_4]^{2-}$, a complex ion with four cyanide ions, CN^-. The metal ion contributes two (+) charges and the four ligands contribute a total of four (−) charges, one for each cyanide ion. The algebraic sum is therefore −2, so the complex ion has a charge of 2−.

The brackets emphasize that the ligands are attached to the metal ion and are not free to roam about. One of the many complex ions formed by the chromium(III) ion contains five water molecules and one chloride ion as ligands. To indicate that all are attached to the Cr^{3+} ion, we use brackets and write the complex ion as $[CrCl(H_2O)_5]^{2+}$. When this complex is isolated as a chloride salt, the formula is written $[CrCl(H_2O)_5]Cl_2$, in which $[CrCl(H_2O)_5]^{2+}$ is the cation and so is written first. The formula $[CrCl(H_2O)_5]Cl_2$ shows that five water molecules and a chloride ion are bonded to the chromium ion, and the other two chloride ions are said to be **counter ions**, meaning they are present to provide electrical neutrality for the salt.

In Chapter 1, you learned about hydrates, and one was the beautiful blue hydrate of copper(II) sulfate, $CuSO_4 \cdot 5H_2O$. It was much too early then to make the distinction, but the formula should have been written as $[Cu(H_2O)_4]SO_4 \cdot H_2O$ to show that four of the five water molecules are held in the crystal as part of the complex ion $[Cu(H_2O)_4]^{2+}$. The fifth water molecule is held in the crystal by being hydrogen bonded to the sulfate ion.

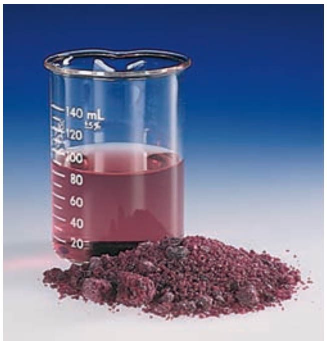


Figure 22.2 | **Color of the cobalt(II) ion in hexahydrate salts.** The ion $[Co(H_2O)_6]^{2+}$ is pink and gives its color both to crystals and to an aqueous solution of $CoCl_2 \cdot 6H_2O$. *(Michael Watson)*

Many other hydrates of metal salts actually contain complex ions of the metals in which water is the ligand. Cobalt salts like cobalt(II) chloride, for example, crystallize from aqueous solutions as hexahydrates (meaning they contain six H_2O molecules per formula unit of the salt). The compound $CoCl_2 \cdot 6H_2O$ (Figure 22.2) actually is $[Co(H_2O)_6]Cl_2$, and it contains the pink complex $[Co(H_2O)_6]^{2+}$. This ion also gives solutions of cobalt(II) salts a pink color as can be seen in Figure 22.2. Although most hydrates of metal salts contain complex ions, the distinction is seldom made, and it's acceptable to write the formula for these hydrates in the usual fashion—for example, $CuSO_4 \cdot 5H_2O$ instead of $[Cu(H_2O)_4]SO_4 \cdot H_2O$.

Example 22.1
Writing the Formula for a Complex Ion

Write the formula for the complex ion formed by the metal ion Cr^{3+} and six NO_2^- ions as ligands. Decide whether the complex could be isolated as a chloride salt or a potassium salt, and write the formula for the appropriate salt.

■ **Analysis:** In this question, we are being asked to determine the formula, including charge, for the complex ion with one Cr^{3+} and six NO_2^-. The net charge on the complex ion will determine whether the salt will be with chloride or potassium. If the complex is a positive ion, it would require a negative ion to form a salt, so it could be isolated as a chloride salt; if the complex is a negative ion, then a potassium salt could form.

■ **Assembling the Tools:** The rules on page 1020 are the tools we'll use to write the formula of the complex ion correctly.

■ **Solution:** Six NO_2^- ions contribute a total charge of 6−; the metal contributes a charge of 3+. The algebraic sum is $(6-) + (3+) = 3-$. The formula of the complex ion is therefore $[Cr(NO_2)_6]^{3-}$.

Because the complex is an anion, it requires a cation to form a neutral salt, so the complex could be isolated as a potassium salt, not as a chloride salt. For the salt to be electrically neutral, three K^+ ions are required for each complex ion, $[Cr(NO_2)_6]^{3-}$. The formula of the salt would therefore be $K_3[Cr(NO_2)_6]$. Notice that in writing the formula for the salt, we've specified the cation (K^+) first, followed by the anion.

■ **Is the Answer Reasonable?** Things to check: Have we written the formula with the metal ion first, followed by the ligands? Have we computed the charge on the complex correctly? Does the formula for the salt correspond to an electrically neutral substance? The answer to each question is yes, so all seems to be okay.

Practice Exercises

22.1 | Write the formula of the complex ion formed by Ag^+ and two thiosulfate ions, $S_2O_3^{2-}$. If we were able to isolate this complex ion as its ammonium salt, what would be the formula for the salt? (*Hint*: Remember, salts are electrically neutral.)

22.2 | Aluminum chloride crystallizes from aqueous solutions as a hexahydrate. Write the formula for the salt and suggest a formula for the complex ion formed by aluminum ion and water.

22.3 | What is the formula of the complex ion that is formed from chromium(III), four water molecules, and two chloride ions? Is the counter ion more likely to be a halide or an alkali metal?

The Chelate Effect

An interesting aspect of the complexes formed by bidentate ligands such as ethylenediamine and oxalate ion is that their stabilities are higher as compared to similar complexes formed by monodentate ligands. For example, the complex $[Ni(en)_3]^{2+}$ is considerably more stable than $[Ni(NH_3)_6]^{2+}$, even though both complexes have six nitrogen atoms bound to a Ni^{2+} ion. We can compare them quantitatively by examining their formation constants:

$$Ni^{2+}(aq) + 6NH_3(aq) \rightleftharpoons [Ni(NH_3)_6]^{2+}(aq) \qquad K_{form} = 2.0 \times 10^8$$
$$Ni^{2+}(aq) + 3en(aq) \rightleftharpoons [Ni(en)_3]^{2+}(aq) \qquad K_{form} = 4.1 \times 10^{17}$$

■ Ammonia, a monodentate ligand, supplies one donor atom to a metal. Ethylenediamine (en), a bidentate ligand, has two nitrogen donor atoms. Therefore, six ammonia molecules and three ethylenediamine molecules supply the same number of donor atoms.

The ethylenediamine complex is more stable than the ammonia complex by a factor of 2×10^9 (2 billion)! This exceptional stability of complexes formed with polydentate ligands is called the **chelate effect**, so named because it occurs in compounds in which the ligands have two or more sites that bind to one metal center. A ring forms involving the metal and the ligand, and extra stability is gained if the ring has five or six atoms in it.

There are two related reasons for the chelate effect, which we can understand best if we examine the ease with which the complexes undergo dissociation once formed. One reason appears to be associated with the probability of the ligand leaving the vicinity of the metal ion when the donor atom becomes detached. If one end of a bidentate ligand comes loose from the metal, the donor atom cannot wander very far because the other end of the ligand is still attached. There is a high probability that the loose end will become reattached to the metal ion before the other end can let go, so overall the ligand appears to be bound tightly. With a monodentate ligand, however, there is nothing to hold the ligand near the metal ion if it becomes detached. The ligand can easily move off into the surrounding solution and be lost. As a result, a monodentate ligand is not as firmly attached to the metal ion as a polydentate ligand.

The second reason is related to the entropy change for the dissociation. In Chapter 19 you learned that when there is an increase in the number of particles in a chemical reaction, the entropy change is positive. Dissociation of both complexes produces more particles, so the entropy change is positive for both of them. However, comparing the two reactions,

$$[\mathrm{Ni(NH_3)_6}]^{2+}(aq) \rightleftharpoons \mathrm{Ni}^{2+}(aq) + 6\mathrm{NH_3}(aq) \qquad K_{\mathrm{inst}} = 5.0 \times 10^{-9}$$

$$[\mathrm{Ni(en)_3}]^{2+}(aq) \rightleftharpoons \mathrm{Ni}^{2+}(aq) + 3\mathrm{en}(aq) \qquad K_{\mathrm{inst}} = 2.4 \times 10^{-18}$$

we see that dissociation of the ammonia complex gives a net increase of *six* in the number of particles, whereas dissociation of the ethylenediamine complex yields a net increase of *three*. This means the entropy change is more positive for the dissociation of the ammonia complex than for the ethylenediamine complex. The larger entropy change translates into a more favorable $\Delta G°$ for the decomposition, so at equilibrium the ammonia complex should be dissociated to a greater extent. This is, in fact, what is suggested by the values of their instability constants, K_{inst} (recall from Section 18.5 that $K_{\mathrm{inst}} = 1/K_{\mathrm{form}}$).

■ Recall that $\Delta G°$ is related to the equilibrium constant. A more favorable $\Delta G°$ for dissociation should yield a larger equilibrium constant, and, indeed, we find the instability constant is larger for the ammonia complex.

A list of ligands is given in Table 22.1. The atom that binds to the metal is underlined. Some ligands can bind through different atoms; for example, the NO_2^- ion can bind either through the N or through the O.

Table 22.1 Some Common Ligands

Name as a Ligand	Formula[a]
acetato	CH_3COO^-
ammine	NH_3
aqua	H_2O
azido	N_3^-
bromo	Br^-
cyano	CN^-
chloro	Cl^-
ethylenediamine (en)	$NH_2CH_2CH_2NH_2$
hydroxo	OH^-
iodo	I^-
nitrito	$ON\underline{O}^-$
nitro	$O\underline{N}O^-$
oxalato (ox^{2-})	$COOCOO^{2-}$
sulfido	S^{2-}
thiosulfato	$S_2OO_2^{2-}$

[a] The underlined elements are the ones that bond to the metal ions.

22.2 | Metal Complex Nomenclature

The naming of chemical compounds was introduced in Chapter 3, where we discussed the nomenclature system for simple inorganic compounds. This system, revised and kept up to date by the International Union of Pure and Applied Chemistry (IUPAC), has been extended to cover metal complexes. Below are some of the rules that have been developed to name coordination complexes. As you will see, some of the names arrived at following the rules are difficult to pronounce at first, and may even sound a little odd. However, the primary purpose of this and any other system of nomenclature is to provide a method that gives each compound its own unique name and permits us to write the formula of the compound given the name.

Rules of Nomenclature for Coordination Complexes

TOOLS

Rules for naming complexes

1. **Cationic species are named before anionic species.** This is the same rule that applies to other ionic compounds such as NaCl, where we name the cation first, followed by the anion (i.e., sodium chloride).
2. **The names of anionic ligands always end in the suffix -o.**
   (a) Ligands whose names end in *-ide* usually have this suffix changed to *-o*.

Anion		Ligand
chloride	Cl^-	chloro-
bromide	Br^-	bromo-
cyanide	CN^-	cyano-
oxide	O^{2-}	oxo-

■ Names such as chloro and bromo in the table at the left are the ones traditionally used and are acceptable. Strict IUPAC names simply drop the -e and replace it with -o to give chlorido, bromido, etc. Thus, S^{2-} would be named sulfido as a ligand.

   (b) Ligands whose names end in *-ite* or *-ate* become *-ito* and *-ato*, respectively.

Anion		Ligand
carbonate	CO_3^{2-}	carbonato-
thiosulfate	$S_2O_3^{2-}$	thiosulfato-
thiocyanate	SCN^-	thiocyanato- (when bonded through sulfur)
		isothiocyanato- (when bonded through nitrogen)
oxalate	$C_2O_4^{2-}$	oxalato-
nitrite	NO_2^-	nitrito- (when bonded through oxygen; written ONO in the formula for the complex)[a]

[a] An exception to this is when the nitrogen of the NO_2^- ion is bonded to the metal, in which case the ligand is named nitro-.

3. **A neutral ligand is given the same name as the neutral molecule.** Thus, the molecule ethylenediamine, when serving as a ligand, is called ethylenediamine in the name of the complex. Two very important exceptions to this, however, are water and ammonia. These are named as follows when they serve as ligands:

   H_2O aqua NH_3 ammine (note the double *m*)

4. **When there is more than one of a particular ligand, their number is specified by the prefixes di- = 2, tri- = 3, tetra- = 4, penta- = 5, hexa- = 6, and so forth. When confusion might result by using these prefixes, the following are used instead: bis = 2, tris = 3, and tetrakis = 4.** Following this rule, the presence of two chloride ligands in a complex would be indicated as *dichloro-* (notice, too, the ending on the ligand name). However, if two ethylenediamine ligands are present, use of the prefix *di-* might cause confusion. Someone reading the name might wonder whether diethylenediamine means two ethylenediamine molecules or one molecule of a substance called diethylenediamine. To avoid this problem we place the ligand name in parentheses preceded by *bis*; that is, *bis(ethylenediamine)*.

■ *Bis-* is employed here so that if the name is used in verbal communication it is clear that the meaning is two ethylenediamine molecules.

5. **In the *formula* of a complex, the symbol for the metal is written first, followed by those of the ligands. Among the ligands, anionic ligands are written first (in alphabetical order), followed by neutral ligands (also in alphabetical order). In the *name* of the complex, the ligands are named first, in alphabetical order *without regard to charge*, followed by the name of the metal**. For example, suppose we had a complex composed of Co^{3+}, two Cl^- (chloro- ligands), one CN^- (cyano- ligand), and three NH_3 (ammine- ligands). The formula of this electrically neutral complex would be written $[CoCl_2(CN)(NH_3)_3]$. In the name of this complex, the ligands would be

specified before the metal as *triamminedichlorocyano-* (*triammine-* for the three NH_3 ligands, *dichloro* for the two Cl^- ligands, and *cyano-* for the CN^- ligand). When alphabetizing the names of the ligands, we ignore the prefixes *tri-* and *di-*. Thus, *triammine-* is written before *dichloro-* because *ammine-* precedes *chloro-* alphabetically. For the same reason, *dichloro-* is written before *cyano*. The complete name for the complex is given below under Rule 7.

■ The ligands are alphabetized according to the first letter of the name of the ligand, not the first letter of the numbering prefix.

6. **Negative (anionic) complex ions always end in the suffix *-ate.*** This suffix is appended to the English name of the metal atom in most cases. However, if the name of the metal ends in *-ium, -um,* or *-ese*, the ending is dropped and replaced by *-ate*.

Metal	Metal as Named in an Anionic Complex
aluminum	aluminate
chromium	chromate
manganese	manganate
nickel	nickelate
cobalt	cobaltate
zinc	zincate
platinum	platinate
vanadium	vanadate

For metals whose symbols are derived from their Latin names, the suffix *-ate* is appended to the Latin stem. (An exception, however, is mercury; in an anion it is named *mercurate.*)

Metal	Stem	Metal as Named in an Anionic Complex
iron	ferr-	ferrate
copper	cupr-	cuprate
lead	plumb-	plumbate
silver	argent-	argentate
gold	aur-	aurate
tin	stann-	stannate

For neutral or positively charged complexes, the metal is *always* specified with the English name for the element, *without any suffix*.

7. **The oxidation state of the metal in the complex is written in Roman numerals within parentheses following the name of the metal.**[3] For example,

$[CoCl_2(CN)(NH_3)_3]$ is triamminedichlorocyanocobalt(III)

$[Co(NH_3)_6]^{3+}$ is the hexaamminecobalt(III) ion

$[CuCl_4]^{2-}$ is the tetrachlorocuprate(II) ion

No spaces

Notice that there are no spaces between the names of the ligands and the name of the metal, and that there is no space between the name of the metal and the parentheses that enclose the oxidation state expressed in Roman numerals.

---

[3] Alternatively, the charge on the complex as a whole can be used instead of the oxidation number—for example, tetrachloridocuprate(2−).

The following are some additional examples. Study them carefully to see how the nomenclature rules apply. Then try the practice exercises that follow.

$[Ni(CN)_4]^{2-}$	tetracyanonickelate(II) ion
$K_3[CoCl_6]$	potassium hexachlorocobaltate(III)
$[CoCl_2(NH_3)_4]^+$	tetraamminedichlorocobalt(III) ion
$Na_3[Co(NO_2)_6]$	sodium hexanitrocobaltate(III)
$[Ag(NH_3)_2]^+$	diamminesilver(I) ion
$[Ag(S_2O_3)_2]^{3-}$	dithiosulfatoargentate(I) ion
$[Mn(en)_3]Cl_2$	tris(ethylenediamine)manganese(II) chloride
$[PtCl_2(NH_3)_2]$	diamminedichloroplatinum(II)

■ Notice, once again, that the alphabetical order of the ligands is determined by the first letter in the name of the ligand, not the first letter in the prefix.

Practice Exercises

22.4 | Write the formula for each of the following: (a) hexachlorostannate(IV) ion, (b) ammonium diaquatetracyanoferrate(II), and (c) dibromobis(ethylenediamine)osmium(II). (*Hint*: Divide each name into its various parts.)

22.5 | Name the following compounds: (a) $K_3[Fe(CN)_6]$, (b) $[CrCl_2(en)_2]_2SO_4$, and (c) $[Co(H_2O)_6]_2[CrF_6]$ (in which the cobalt is in the +2 oxidation state).

22.3 | Coordination Number and Structure

One of the most interesting aspects of the study of complexes is the kinds of structures that they form. In many ways, this is related to the **coordination number** of the metal ion, which we define as *the number of donor atoms attached to the metal ion*. For example, in the complex $[Ni(CN)_4]^{2-}$, four cyanide ions bind the nickel ion, so the coordination number of Ni^{2+} in this complex is 4. Similarly, the coordination number of Cr^{3+} in the $[Cr(H_2O)_6]^{3+}$ ion is 6, and the coordination number of Ag^+ in $[Ag(NH_3)_2]^+$ is 2.

Sometimes the coordination number isn't immediately obvious from the formula of the complex. For example, you learned that there are many polydentate ligands that contain more than one donor atom that can bind simultaneously to a metal ion. Often, a metal is able to accommodate two or more polydentate ligands to give complexes with formulas such as $[Cr(H_2O)_2(en)_2]^{3+}$ and $[Cr(en)_3]^{3+}$. In each of these examples, the coordination number of the Cr^{3+} is 6. In the $[Cr(en)_3]^{3+}$ ion, there are three ethylenediamine ligands that each supply two donor atoms, for a total of 6, and in $[Cr(H_2O)_2(en)_2]^{3+}$, the two ethylenediamine ligands supply a total of 4 donor atoms and the two H_2O molecules supply another 2, so once again the total is 6.

Coordination Number and Geometry

For metal complexes, there are certain geometries that are usually associated with particular coordination numbers.

■ Ordinarily, the VSEPR model isn't used to predict the structures of transition metal complexes because it can't be relied on to give correct results when the metal has a partially filled *d* subshell.

Coordination Number 2

Examples are complexes such as $[Ag(NH_3)_2]^+$ and $[Ag(CN)_2]^-$. Usually, these complexes have a linear structure such as

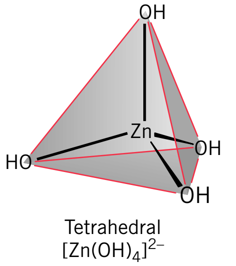
$$[H_3N\text{—}Ag\text{—}NH_3]^+ \quad \text{and} \quad [NC\text{—}Ag\text{—}CN]^-$$

(Since the Ag^+ ion has a filled *d* subshell, it behaves as any of the representative elements as far as predicting geometry by VSEPR theory, so these structures are exactly what we would expect based on that theoretical model.)

Coordination Number 4

Two common geometries occur when four ligand atoms are bonded to a metal ion—tetrahedral and square planar. These are illustrated in Figure 22.3. The tetrahedral geometry is usually found with metal ions that have completely filled *d* subshells, such as Zn^{2+}. The complexes $[Zn(NH_3)_4]^{2+}$ and $[Zn(OH)_4]^{2-}$ are examples.

Square planar geometries are observed for complexes of Cu^{2+}, Ni^{2+}, Pd^{2+} and especially Pt^{2+}. Examples are $[Cu(NH_3)_4]^{2+}$, $[Ni(CN)_4]^{2-}$, and $[PtCl_4]^{2-}$. The most well-studied square planar complexes are those of Pt^{2+}, because they are considerably more stable than the others.



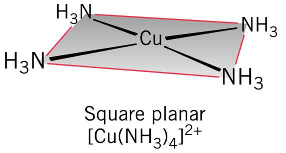


Figure 22.3 | **Tetrahedral and square planar geometries.** These are structures that occur for complexes in which the metal ion has a coordination number of 4. For the copper complex, we are viewing the square planar structure tilted back into the plane of the page.

Coordination Number 6

The most common coordination number for complex ions is 6. Examples are $[Al(H_2O)_6]^{3+}$, $[Co(C_2O_4)_3]^{3-}$, $[Ni(en)_3]^{2+}$, and $[Co(EDTA)]^-$. With few exceptions, all complexes with a coordination number of 6 are octahedral. This holds true for those formed from both monodentate and bidentate ligands, as illustrated in Figure 22.4. In describing the shapes of octahedral complexes, most chemists use one of the drawings of the octahedron shown in Figure 22.5. Some common coordination numbers for the metal ions are summarized in Table 22.2.

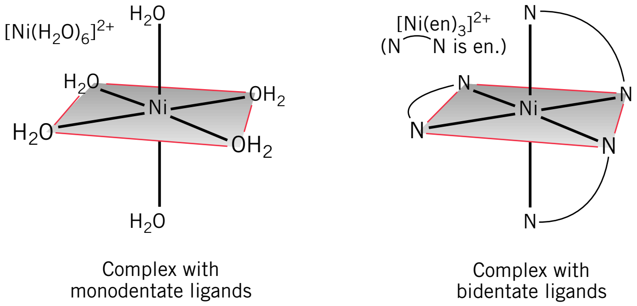

Figure 22.4 | **Octahedral complexes.** Complexes with this geometry can be formed with either monodentate ligands, such as water, or with polydentate ligands, such as ethylenediamine (en). To simplify the drawing of the ethylenediamine complex, the atoms joining the donor nitrogen atoms in the ligand, —CH_2—CH_2—, are represented as the curved line between the N atoms. Also notice that the nitrogen atoms of the bidentate ligand span adjacent positions within the octahedron. This is the case for all polydentate ligands that you will encounter in this book.

Table 22.2 Some Common Coordination Numbers of Metal Ions

Metal Ion	Coordination Number	Metal Ion	Coordination Number
Al^{3+}	4, 6	Ni^{2+}	4, 6
Sc^{3+}	6	Cu^+	2, 4
Ti^{4+}	6	Cu^{2+}	4, 6
V^{3+}	6	Zn^{2+}	4
Cr^{3+}	6	Pd^{2+}	4
Mn^{2+}	6	Ag^+	2
Fe^{2+}	6	Pt^{2+}	4
Fe^{3+}	6	Pt^{4+}	6
Co^{2+}	4, 6	Au^+	2, 4
Co^{3+}	6	Au^{3+}	4

Practice Exercises

22.6 | What is the coordination number of the metal ion in $[Cr(C_2O_4)_3]^{3-}$? (*Hint*: Identify the ligand and sketch its structure.)

22.7 | What is the coordination number of the metal ion in (a) $[CoCl_2(C_2O_4)_2]^{3-}$, (b) $[Cr(C_2O_4)_2(en)]^-$, and (c) $[Co(EDTA)]^-$?

22.8 | What is the coordination number of the metal ion in (a) $[PtCl_2(NH_3)_2]$ and (b) $[Ag(S_2O_3)_2]^{3-}$? What are the coordination geometries for the complexes?

22.4 | Isomers of Metal Complexes

When you write the chemical formula for a compound, you might be tempted to think that you should also be able to predict exactly what the structure of the molecule or ion is. As you may realize by now, this just isn't possible in many cases. Sometimes we can use simple rules to make reasonable structural guesses, as in the discussion of the drawing of Lewis structures in Chapter 9, but these rules apply only to simple molecules and ions. For more complex substances, there usually is no way of knowing for sure what the structure of the molecule or ion is without performing the necessary experiments to determine the structure.

One of the reasons that structures can't be predicted with certainty from chemical formulas alone is that there are usually many different ways that the atoms in the formula can be arranged. In fact, it is frequently possible to isolate two or more compounds that actually have the same chemical formula. For example, three different solids, each with its own characteristic color and other properties, can be isolated from a solution of chromium(III) chloride. All three have the same overall composition, and in the absence of other data, their formulas are written $CrCl_3 \cdot 6H_2O$. However, experiments have

Chromium(III) chloride hexahydrate. The hydrated chromium(III) chloride purchased from chemical supply companies is actually $[CrCl_2(H_2O)_4]Cl \cdot 2H_2O$. Its green color in both the solid state and solution is due to the complex ion, $[CrCl_2(H_2O)_4]^+$. *(Michael Watson)* shown that these solids are actually the salts of three different complex ions. Their actual formulas (and colors) are

$[Cr(H_2O)_6]Cl_3$	purple
$[CrCl(H_2O)_5]Cl_2 \cdot H_2O$	blue-green
$[CrCl_2(H_2O)_4]Cl \cdot 2H_2O$	green

Even though their overall compositions are the same, each of these substances is a distinct chemical compound with its own unique set of properties.

The existence of two or more compounds, each having the same chemical formula, is known as **isomerism.** In the preceding example, each salt is said to be an **isomer** of $CrCl_3 \cdot 6H_2O$. For coordination compounds, isomerism can occur in a variety of ways. In the case of $CrCl_3 \cdot 6H_2O$, isomers exist because of the different possible ways that the water molecules and chloride ions can be held in the crystals. In one instance, all of the water molecules serve as ligands, while in the other two, part of the water is present as water of hydration and some of the chloride is bonded to the metal ion. Another example, which is similar in some respects, is $Cr(NH_3)_5SO_4Br$. This "substance" can be isolated as two isomers:

$$[CrSO_4(NH_3)_5]Br \quad \text{and} \quad [CrBr(NH_3)_5]SO_4$$

■ Ag_2SO_4 is soluble but $BaSO_4$ is insoluble.
$BaBr_2$ is soluble but AgBr is insoluble.

They can be distinguished chemically by their differing abilities to react with Ag^+ and Ba^{2+}. The first isomer reacts in aqueous solution with Ag^+ to give a precipitate of AgBr, but it doesn't react with Ba^{2+}. This tells us that Br^- exists as a free ion in the solution. It also suggests that the SO_4^{2-} is bound to the chromium and is unavailable to react with Ba^{2+} to give insoluble $BaSO_4$.

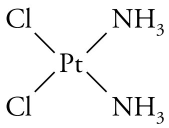
Aqueous solutions of the second isomer, $[CrBr(NH_3)_5]SO_4$, reacts in solution with Ba^{2+} to give a precipitate of $BaSO_4$, which means there is free SO_4^{2-} in the solution. There is no reaction with Ag^+, however, because Br^- is bonded to the chromium and is unavailable as free Br^- in the solution. Thus, even though both isomers have the same overall composition, they behave chemically in quite different ways and are therefore distinctly different compounds.

Stereoisomerism

One of the most interesting kinds of isomerism found among coordination compounds is called **stereoisomerism**, which is defined as *differences among isomers that arise as a result of the various possible orientations of their atoms in space*. In other words, when stereoisomerism exists, we have compounds in which the same atoms are attached to each other, but they differ in the way those atoms are arranged in space relative to one another.

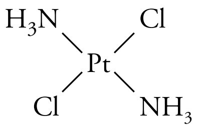
One form of stereoisomerism is called **geometric isomerism**; it is best understood by referring to an example. Consider the square planar complexes having the formula $PtCl_2(NH_3)_2$. There are two ways to arrange the ligands around the platinum, as illustrated below. In one isomer, called the ***cis* isomer**, the chloride ions are *next to each other* and the ammonia molecules are also next to each other. In the other isomer, called the ***trans* isomer**, identical ligands are *opposite each other*. In identifying (and naming) isomers, *cis* means "on the same side," whereas *trans* means "on opposite sides."

■ The isomer on the left, *cis*-$PtCl_2(NH_3)_2$, is the anticancer drug known as *cisplatin*. It is interesting that only the *cis* isomer of this compound is clinically active against tumors. The *trans* isomer is totally ineffective.



cis isomer
cis-diamminedichloroplatinum(II)

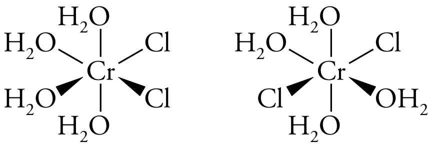
and



trans isomer
trans-diamminedichloroplatinum(II)

Geometric isomerism also occurs for octahedral complexes. For example, consider the ions $[CrCl_2(H_2O)_4]^+$ and $[CrCl_2(en)_2]^+$. Both can be isolated as *cis* and *trans* isomers.

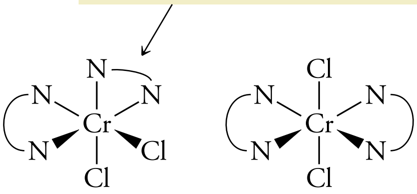
■ The structures of the octahedral complexes are being drawn following the method in Figure 22.5*b*.



cis *trans*

$[CrCl_2(H_2O)_4]^+$

Curved lines connecting nitrogen atoms represent —CH_2—CH_2—, which links the nitrogen atoms in ethylenediamine.



cis *trans*

$[CrCl_2(en)_2]^+$

N N is en (ethylenediamine), $NH_2CH_2CH_2NH_2$

In the *cis* isomer, the chloride ligands are both on the same side of the metal ion; in the *trans* isomer, the chloride ligands are on opposite ends of a line that passes through the center of the metal ion.

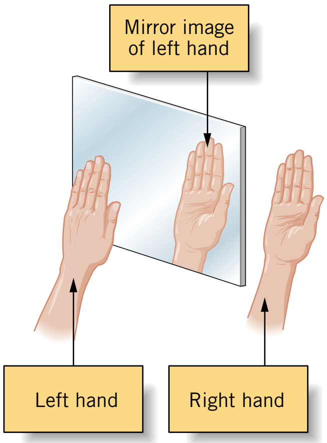
Figure 22.6 | **One difference between left and right hands.** A left-hand glove won't fit the right hand. *(Michael Watson)*

Chirality

There is a second kind of stereoisomerism that is much more subtle than geometric isomerism. This occurs when molecules are exactly the same except for one small difference—they are *nonsuperimposable mirror images of each other*. They bear the same relationship to each other as do your left and right hands. (In fact this relationship between such isomers is sometimes referred to by the term *handedness*.)

Although similar in appearance, your two hands are not exactly alike. If you place one hand over the other, palms down, your thumbs point in opposite directions. **Superimposability** is the ability of two objects to fit "one within the other" with no mismatch of parts. Your left and right hands lack this ability, so we say they are *nonsuperimposable*. This is why your right hand doesn't fit into your left-hand glove (Figure 22.6); your right hand does not match *exactly* the space that corresponds to your left hand.

Your hands are also mirror images of each other. If you hold your left hand so it faces a mirror, and then look at its reflection as illustrated in Figure 22.7, you will see that it looks exactly like your right hand. If it were possible to reach "through the looking glass," your right-hand glove would fit the reflection of your left hand perfectly. Thus, your two hands are *nonsuperimposable mirror images* of each other. If two objects are nonsuperimposable mirror images of each other, they are not identical and are said to be **chiral** or have **chirality**. Your left and right hands have this property and are not exactly alike.



Mirror image of left hand

Right hand
Figure 22.7 | **Hands are mirror images of each other.** The image of the left hand reflected in the mirror appears the same as the right hand.

Chiral Complexes with Bidentate Ligands

The most common examples of chirality among coordination compounds occur with octahedral complexes that contain two or three bidentate ligands—for instance, $[CoCl_2(en)_2]^+$ and $[Co(en)_3]^{3+}$. For the complex $[Co(en)_3]^{3+}$, the two nonsuperimposable isomers, called **enantiomers**, are shown in Figure 22.8. For the complex $[CoCl_2(en)_2]^+$, only the *cis* isomer is chiral, as described in Figure 22.9.

■ Chirality is the technical term for "handedness," meaning objects structurally related to each other as are our left and right hands.

Figure 22.8 | **The two isomers of $[Co(en)_3]^{3+}$.** Isomer II is constructed as the mirror image of isomer I. No matter how Isomer II is turned about, it is not superimposable on Isomer I.

Co
N

As you can see, chiral isomers differ in only a very minor way from each other. This difference is so subtle that most of their properties are identical. They have identical melting points and boiling points, and in nearly all of their reactions, their behavior is exactly alike. The only way that the difference between chiral molecules or ions manifests itself is in the way that they interact with physical or chemical "probes" that also have a handedness about them. For example, if two reactants are both chiral, then a given isomer of one of them will usually behave slightly differently toward each of the two isomers of the other reactant. This has very profound effects in biochemical reactions, in which many of the molecules involved are chiral.

Optical Isomers

One way that chiral isomers differ is in the way they affect polarized light. Light is *electromagnetic radiation* that possesses both electric and magnetic components that behave like vectors. These vectors oscillate in directions perpendicular to the direction in which the light wave is traveling (Figure 22.10*a*). In ordinary light, the oscillations of the electric and magnetic fields of the photons are oriented randomly around the direction of the light

Figure 22.10 | **Unpolarized and polarized light.** (*a*) Light possesses electric and magnetic components that oscillate perpendicular to the direction of the propagation of the light wave. (*b*) In unpolarized light, the electromagnetic oscillations of the photons are oriented at random angles around the axis of the propagation of the light wave. The polarizing filter has the effect of preventing oscillations from passing through unless they are in one particular plane. The result is called plane polarized light.

beam. In **plane-polarized light**, all of the oscillations occur in the same plane (Figure 22.10*b*). Ordinary light can be polarized in several ways. One is to pass it through a special film of plastic, as in a pair of Polaroid sunglasses. This has the effect of filtering out all of the vibrations except those that are in one plane (Figure 22.10*b*).

Chiral isomers like those described in Figures 22.8 and 22.9 have the ability to rotate plane polarized light, as illustrated in Figure 22.11. Because of this phenomenon, chiral isomers are said to be **optical isomers**.

In this illustration, the plane of polarization of the light is rotated to the left (as seen facing the light source).

22.5 | Bonding in Metal Complexes

Complexes of the transition metals differ from the complexes of other metals in two special ways: (1) they are usually colored, whereas complexes of the representative metals are usually (but not always) colorless, and (2) their magnetic properties are often affected by the ligands attached to the metal ion. For example, it is not unusual for a given metal ion to form complexes with different ligands to give a rainbow of colors, as illustrated in Figure 22.12 for a series of complexes of cobalt. Also, because transition metal ions often have incompletely filled *d* subshells, we expect to find many of them with unpaired *d* electrons, and compounds that contain them should be paramagnetic. However, for a given metal ion, the number of unpaired electrons is not always the same from one complex to another. For example, Fe^{2+} has four of its six 3*d* electrons unpaired in the $[Fe(H_2O)_6]^{2+}$ ion, but all of its electrons are paired in the $[Fe(CN)_6]^{4-}$ ion. As a result, the $[Fe(H_2O)_6]^{2+}$ ion is paramagnetic and the $[Fe(CN)_6]^{4-}$ ion is diamagnetic.

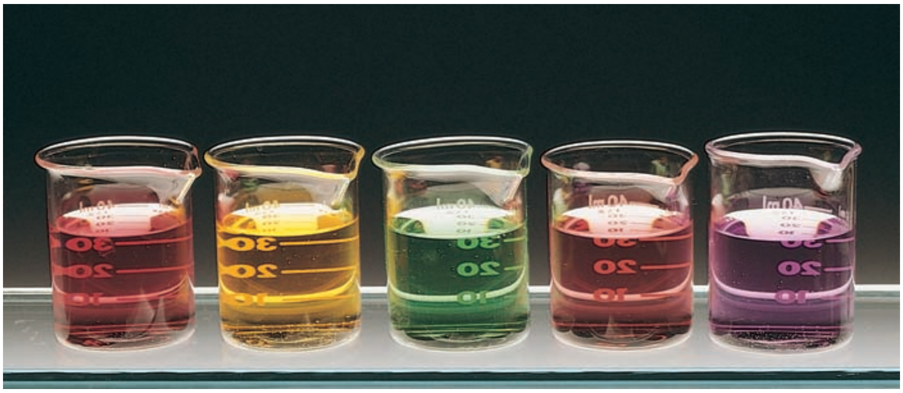

Figure 22.12 | **Colors of complex ions depend on the nature of the ligands.** Each of these brightly colored solutions contains a complex ion of Co^{3+}. The variety of colors arises because of the different ligands (molecules or anions) that are bonded to the cobalt ion in the complexes. *(Michael Watson)*

Crystal Field Theory

Any theory that attempts to explain the bonding in complex ions must also explain their colors and magnetic properties. One of the simplest theories that does this is the **crystal field theory**. This theory gets its name from its original use in explaining the behavior of transition metal ions in crystals. It was discovered later that the theory also works well for transition metal complexes.

Crystal field theory ignores covalent bonding in complexes. It assumes that the primary stability comes from the electrostatic attractions between the positively charged metal ion and the negative charges of the electrons being donated by the ligands. Crystal field theory's unique approach, though, is the way it examines how the negative charges on the ligands affect the energy of the complex by influencing the energies of the *d* orbitals of the metal ion, and this is what we will focus our attention on here. To understand the theory, therefore, it is essential that you know the shapes and orientation of the *d* orbitals. The *d* orbitals were described in Chapter 8, and they are illustrated again in Figure 22.13.

■ More complete theories consider the covalent nature of metal–ligand bonding, but crystal field theory nevertheless provides a useful model for explaining the colors and magnetic properties of complexes.

■ The labels for the *d* orbitals come from the mathematics of quantum mechanics.

First, notice that four of the *d* orbitals have the same shape but point in different directions. These are the $d_{x^2-y^2}$, d_{xy}, d_{xz}, and d_{yz} orbitals. Each has four lobes of electron density. The fifth *d* orbital, labeled d_{z^2}, has two lobes that point in opposite directions along the *z* axis plus a small donut-shaped ring of electron density around the center that is concentrated in the *xy* plane.

Of prime importance to us are the *directions* in which the lobes of the *d* orbitals point. Notice that three of them—d_{xy}, d_{xz}, and d_{yz}—point *between* the *x*, *y*, and *z* axes. The other two—the d_{z^2} and $d_{x^2-y^2}$ orbitals—have their maximum electron densities *along* the *x*, *y*, and *z* axes.

Now let's consider constructing an octahedral complex within this coordinate system. We can do this by bringing ligands in along each of the axes as shown in Figure 22.14. The question we want to answer is: How do these ligands affect the energies of the *d* orbitals?

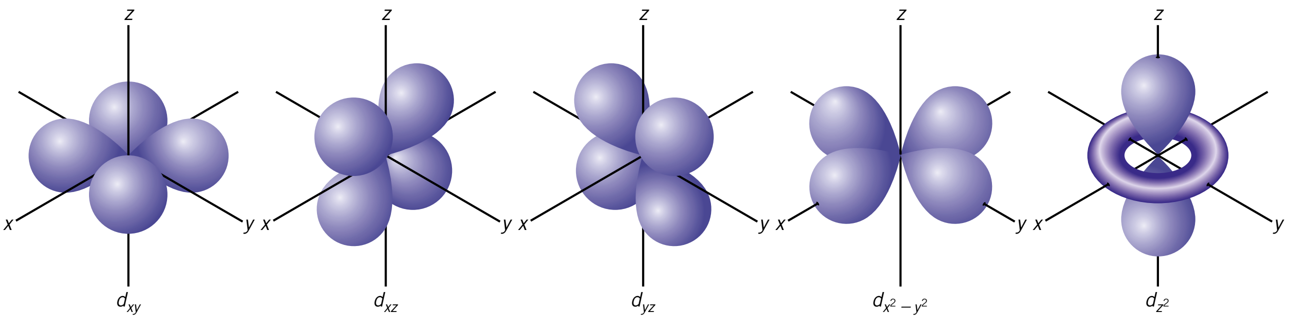

Figure 22.13 | **The shapes and directional properties of the five *d* orbitals of a *d* subshell.**

In an isolated atom or ion, all of the *d* orbitals of a given *d* subshell have the same energy. Therefore, an electron will have the same energy regardless of which *d* orbital it occupies. In an octahedral complex, however, this is no longer true. If the electron is in the $d_{x^2-y^2}$ or d_{z^2} orbital, it is forced to be nearer the negative charge of the ligands than if it is in a d_{xy}, d_{xz}, or d_{yz} orbital. Since the electron itself is negatively charged and is repelled by the charges of the ligands, the electron's potential energy will be higher in the $d_{x^2-y^2}$ and d_{z^2} orbitals than in a d_{xy}, d_{xz}, or d_{yz} orbital. Therefore, as the complex is formed, the *d* subshell actually splits into *two* new energy levels, as shown in Figure 22.15. Here we see that regardless of which orbital the electron occupies, its energy increases because it is repelled by the negative charges of the approaching ligands. However, the electron is repelled *more* (and has a higher energy) if it is in an orbital that points directly at the ligands than if it occupies an orbital that points between them.

In an octahedral complex, the energy difference between the two sets of *d*-orbital energy levels is called the **crystal field splitting**. It is usually given the symbol Δ (delta), and its magnitude depends on the following factors:

The nature of the ligand*. Some ligands produce a larger splitting of the energies of the d orbitals than others.* For a given metal ion, for example, cyanide always gives a large value of Δ and F^- always gives a small value. We will have more to say about this later.

The oxidation state of the metal*. For a given metal and ligand, the size of* Δ *increases with an increase in the oxidation number of the metal.* As electrons are removed from a metal and the charge on the ion becomes more positive, the ion becomes smaller. This means that the ligands are attracted to the metal more strongly and they can approach the center of the complex more closely. As a result, they also approach the *d* orbitals along the *x*, *y*, and *z* axes more closely, and thereby cause a greater repulsion. This causes a greater splitting of the two *d*-orbital energy levels and a larger value of Δ.

The row in which the metal occurs in the periodic table*. For a given ligand and oxidation state, the size of* Δ *increases going down a group.* In other words, for a given ligand, an ion of an element in the first row of transition elements has a smaller value of Δ than the ion of a heavier member of the same group. Thus, comparing complexes of Ni^{2+} and Pt^{2+} with the same ligand, we find that the platinum complex has the larger crystal field splitting. The explanation of this is that in the larger ion (e.g., Pt^{2+}), the *d* orbitals are larger and more diffuse and extend farther from the nucleus in the direction of the ligands. This produces a larger repulsion between the ligands and the orbitals that point at them.

The magnitude of Δ is very important in determining the properties of complexes, including the stabilities of oxidation states of the metal ions, the colors of complexes, and their magnetic properties. Let's look at some examples.

TOOLS

Crystal field splitting pattern for octahedral complexes

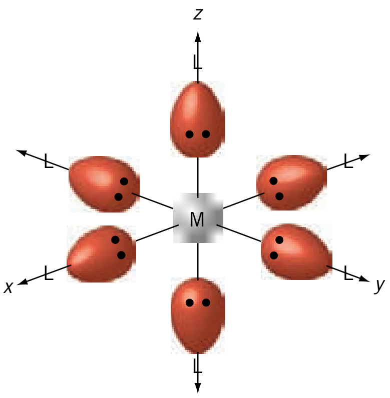

Figure 22.14 | **An octahedral complex ion with ligands that lie along the *x*, *y*, *and z axes*.** The dots represent the lone electron pairs on the ligands, which are oriented so that they point at the metal ion.

Energy
Decreasing distance between metal ion and the ligands

Figure 22.15 | **The changes in the energies of the *d* orbitals of a metal ion as an octahedral complex is formed.** As the ligands approach the metal ion, the *d* orbitals split into two new energy levels.

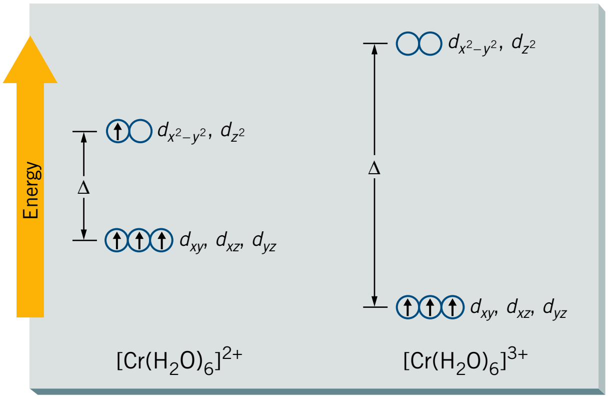

Figure 22.16 | **Energy level diagrams for the $[Cr(H_2O)_6]^{2+}$ and $[Cr(H_2O)_6]^{3+}$ ions.** The magnitude of Δ is larger for the chromium(III) complex because the Cr^{3+} ion is smaller than the Cr^{2+} ion and the ligands are drawn closer to the metal ion, thereby increasing repulsions felt by the $d_{x^2-y^2}$ and d_{z^2} orbitals.

Stabilities of Oxidation States

Comparing the cations formed by chromium, it is found that the Cr^{2+} ion is very easily oxidized to Cr^{3+}. This can be explained by crystal field theory. In water, we expect these ions to exist as the complexes $[Cr(H_2O)_6]^{2+}$ and $[Cr(H_2O)_6]^{3+}$, respectively. Let's examine the energies and electron populations of the *d*-orbital energy levels in each complex (Figure 22.16).

The element chromium has the electron configuration

$$\text{Cr} \qquad [\text{Ar}]\ 3d^5 4s^1$$

Removing two electrons gives the Cr^{2+} ion, and removing three gives Cr^{3+}:

$$\text{Cr}^{2+} \qquad [\text{Ar}]\ 3d^4$$
$$\text{Cr}^{3+} \qquad [\text{Ar}]\ 3d^3$$

Next, we distribute the *d* electrons among the various *d* orbitals following Hund's rule, but for Cr^{2+} we have to make a choice. Should the electrons all be forced into the lower of the two energy levels, or should they be spread out? From the diagram we see that the fourth electron does not pair with one of the others in the lower energy *d*-orbital level. Instead, three electrons go into the lower level and the fourth is in the upper level. We will discuss *why* this happens later, but for now, let's use the two energy diagrams to explain why Cr^{2+} is so easy to oxidize.

There are actually two factors that favor the oxidation of Cr(II) to Cr(III). First, the electron that is removed from Cr^{2+} to give Cr^{3+} comes from the *higher* energy level, so oxidizing the chromium(II) *removes* a high-energy electron. The second factor is the effect caused by increasing the oxidation state of the chromium. As we've pointed out, this increases the magnitude of Δ, and as you can see, the energy of the three electrons that remain is lowered. Thus, both the removal of a high-energy electron and the lowering of the energy of the electrons that are left behind help make the oxidation occur, so the $[Cr(H_2O)_6]^{2+}$ ion is very easily oxidized to $[Cr(H_2O)_6]^{3+}$.

Colors of Metal Complexes

When light is absorbed by an atom, molecule, or ion, the energy of the photon raises an electron from one energy level to another. In many substances, such as sodium chloride, the energy difference between the highest energy populated level and the lowest energy unpopulated level is quite large, so the frequency of a photon that carries the necessary energy lies outside the visible region of the spectrum. The substance appears white because visible light is unaffected; it is reflected unchanged.

■ Remember, $E = h\nu$. The energy of the photon absorbed determines the frequency (and wavelength) of the absorbed light.

For complex ions of the transition metals, the energy difference between the *d*-orbital energy levels is not very large, and photons with frequencies in the visible region of the spectrum are able to raise an electron from the lower-energy set of *d* orbitals to the higher-energy set. This is shown in Figure 22.17 for the $[Cr(H_2O)_6]^{3+}$ ion.

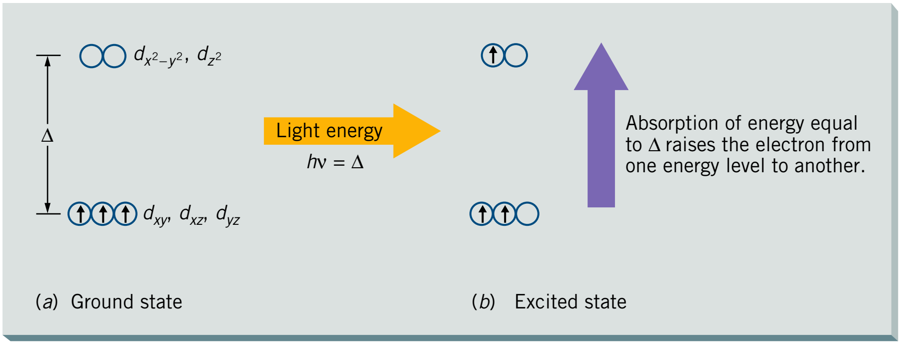

Figure 22.17 | **Absorption of a photon by the $[Cr(H_2O)_6]^{3+}$ complex.** (*a*) The electron distribution in the ground state of the $[Cr(H_2O)_6]^{3+}$ ion. (*b*) Light energy raises an electron from the lower energy set of *d* orbitals to the higher energy set.

Blue-violet

Figure 22.18 | **A color wheel.** Colors that are across from each other are called complementary colors. When a substance absorbs a particular color, light that is reflected or transmitted has the color of its complement. Thus, something that absorbs red light appears green-blue, and vice versa.

As you know, white light contains photons of all of the frequencies and colors in the visible spectrum. If we shine white light through a solution of a complex, the light that passes through has all of the colors *except* those that have been absorbed. It is not difficult to determine what will be seen if we know what colors are being absorbed. All we need is a color wheel like the one shown in Figure 22.18. Across from each other on the color wheel are ***complementary colors***. Green-blue is the complementary color to red, and yellow is the complementary color to violet-blue. If a substance absorbs a particular color when bathed in white light, the perceived color of the reflected or transmitted light is the complementary color. In the case of the $[Cr(H_2O)_6]^{3+}$ ion, the light absorbed when the electron is raised from one set of *d* orbitals to the other has a frequency of 5.22×10^{14} Hz, which is the color of yellow light. This is why a solution of this ion appears violet.[4] An instrument that measures the wavelength of light and the amount of light absorbed by a compound is a spectrophotometer (shown in Figure 22.19).

Because of the relationship between the energy and the frequency of light, we see that the color of the light absorbed by a complex depends on the magnitude of Δ; the larger the size of Δ, the more energy the photon must have and the higher will be the frequency of the absorbed light. For a given metal in a given oxidation state, the size of Δ depends on the ligand. Some ligands give a large crystal field splitting, while others give a small splitting. For example, ammonia produces a larger splitting than water, so the complex $[Cr(NH_3)_6]^{3+}$ absorbs light of higher energy and higher frequency than $[Cr(H_2O)_6]^{3+}$. (The $[Cr(NH_3)_6]^{3+}$ absorbs blue light and appears yellow.) Because changing the ligand changes Δ, the same metal ion is able to form a variety of complexes with a large range of colors.

Figure 22.19 | **A spectrophotometer typically found in an undergraduate teaching laboratory.**

A ligand that produces a large crystal field splitting with one metal ion also produces a large Δ in complexes with other metals. For example, cyanide ion is a very effective ligand and always gives a very large Δ, regardless of the metal to which it is bound. Ammonia is less effective than cyanide ion but more effective than water. Thus, ligands can be arranged

---

[4] The perception of color is actually somewhat more complex than this because of the varying sensitivity of the human eye to various wavelengths. For example, the eye is much more sensitive to green than to red. If a compound reflects both of these colors with equal intensity, it will appear greenish simply because the eye sees green better than it sees red.

■ The order of the ligands can be determined by measuring the frequencies of the light absorbed by complexes.

TOOLS Spectrochemical series

in order of their effectiveness at producing a large crystal field splitting. This sequence is called the **spectrochemical series.** Such a series containing some common ligands arranged in order of their decreasing strength is

$$CN^- > NO_2^- > en > NH_3 > H_2O > C_2O_4^{2-} > OH^- > F^- > Cl^- > Br^- > I^-$$

For a given metal ion, cyanide ion produces the largest Δ and iodide produces the smallest.

Magnetic Properties of Complexes

Let's return to the question of the electron distribution among the *d* orbitals in Cr^{2+} complexes. As you saw above, this ion has four *d* electrons, and we noted that in placing these electrons in the *d* orbitals, we had to make a decision about where to place the fourth electron. There's no question about the fate of the first three. They just spread out across the three *d* orbitals in the lower level with their spins unpaired. In other words, we just follow Hund's rule, which we learned to apply in Chapter 8. However, when we come to the fourth electron we have to decide whether to pair it with one of the electrons already in a *d* orbital of the lower set or to place it in one of the *d* orbitals of the higher set.[5] If we place it in the lower energy level, we give it extra stability (lower energy), but some of this stability is lost because it requires energy, called the **pairing energy**, *P*, to force the electron into an orbital that's already occupied by an electron. On the other hand, if we place it in the higher level, we are relieved of the burden of pairing the electron, but it also tends to give the electron a higher energy. Thus, for the fourth electron, "pairing" and "placing" affect the energy of the complex in opposite ways.

The critical factor in determining whether the fourth electron enters the lower level and becomes paired, or whether it enters the higher level with the same spin as the other *d* electrons, is the magnitude of Δ. If Δ is larger than the pairing energy *P*, then greater stability is achieved if the fourth electron is paired with one in the lower level. If Δ is small compared to *P*, then greater stability is obtained by spreading the electrons out as much as possible. The complexes $[Cr(H_2O)_6]^{2+}$ and $[Cr(CN)_6]^{4-}$ illustrate this well.

Water is a ligand that does not produce a large Δ, so $P > \Delta$, and minimum pairing of the electrons takes place. This explains the energy level diagram for the $[Cr(H_2O)_6]^{2+}$ complex in Figure 22.20*a*. When cyanide is the ligand, however, a very large Δ is obtained, and this leads to pairing of the fourth electron with one in the lower set of *d* orbitals. This is shown in Figure 22.20*b*. By measuring the degree of paramagnetism of the two complexes, it can be demonstrated experimentally that $[Cr(H_2O)_6]^{2+}$ has four unpaired electrons and the $[Cr(CN)_6]^{4-}$ ion has just two.

For octahedral chromium(II) complexes, there are two possibilities in terms of the number of unpaired electrons. They contain either four or two, depending on the magnitude of Δ. When there is the maximum number of unpaired electrons, the complex is described as being **high-spin**; when there is the minimum number of unpaired electrons it is described as being **low-spin**. High- and low-spin octahedral complexes are possible

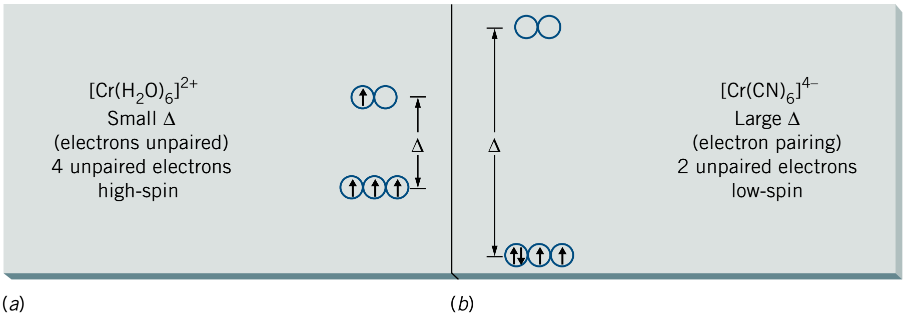

Figure 22.20 | **The effect of Δ on the electron distribution in a complex with four *d* electrons.** (*a*) When Δ is small, the electrons remain unpaired. (*b*) When Δ is large, the lower energy level accepts all four electrons and two electrons become paired.

---

[5] We've never had to make this kind of decision before because the energy levels in atoms were always widely spaced. In complex ions, however, the spacing between the two *d*-orbital energy levels is fairly small.

when the metal has a d^4, d^5, d^6, or d^7 electron configuration. Let's look at another example—one containing the Fe^{2+} ion, which has the electron configuration,

$$Fe^{2+} \qquad [Ar]\ 3d^6$$

At the beginning of this section we mentioned that the $[Fe(H_2O)_6]^{2+}$ ion is paramagnetic and has four unpaired electrons, while the $[Fe(CN)_6]^{4-}$ ion is diamagnetic, meaning it has no unpaired electrons. Now we can see why, by referring to Figure 22.21. Water produces a weak splitting and a minimum amount of pairing of electrons. When the six *d* electrons in the Fe^{2+} ion are distributed, one must be paired in the lower level after filling the upper level. The result is four unpaired *d* electrons, and a high-spin complex. Cyanide ion, however, produces a large splitting, so $\Delta > P$. This means that maximum pairing of electrons in the lower level takes place, and a low-spin complex is formed. Six electrons are just the right amount to completely fill all three of these *d* orbitals, and since all of the electrons are paired, the complex is diamagnetic.

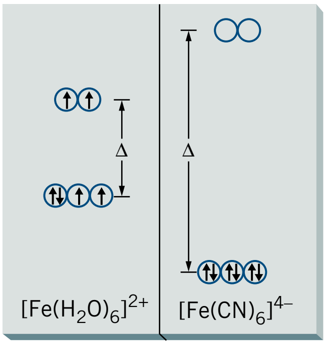

Figure 22.21 | **The distribution of *d* electrons in $[Fe(H_2O)_6]^{2+}$ and $[Fe(CN)_6]^{4-}$.** The magnitude of Δ for the cyanide complex is much larger than for the water complex. This produces a maximum pairing of electrons in the lower energy set of *d* orbitals in $[Fe(CN)_6]^{4-}$.

Crystal Field Theory and Other Geometries

The crystal field theory can be extended to geometries other than octahedral. The effect that changing the structure of the complex has on the energies of the *d* orbitals is to change the splitting pattern.

Square Planar Complexes

We can form a square planar complex from an octahedral one by removing the ligands that lie along the *z* axis. As this happens, the ligands in the *xy* plane are able to approach the metal a little closer because they are no longer being repelled by ligands along the *z* axis. The effect of these changes on the energies of the *d* orbitals is illustrated in Figure 22.22.

■ In Figure 22.22, as the energies of the *d* orbitals change, the d_{z^2} orbital drops in energy by the same amount as the $d_{x^2-y^2}$ rises. Similarly, the energies of the d_{xz} and d_{yz} orbitals drop only half as much as the energy of the d_{yz} rises. In this way, if all the *d* orbitals were filled, the changes in geometry would have no effect on the total energy of the complex.

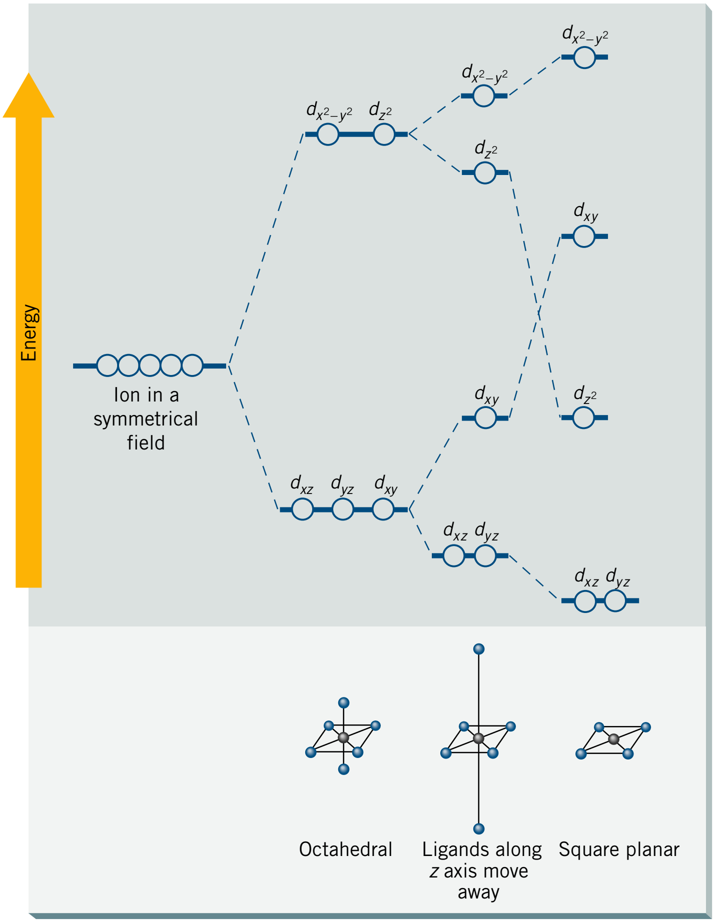

Figure 22.22 | **Energies of *d* orbitals in complexes with various structures.** The splitting pattern of the *d* orbitals changes as the geometry of the complex changes.

The repulsions felt by the *d* orbitals that point in the *z* direction are reduced, so we find that the energies of the d_{z^2}, d_{xz}, and d_{yz} orbitals drop. At the same time, the energies of the orbitals in the *xy* plane feel greater repulsions, so the $d_{x^2-y^2}$ and d_{xy} rise in energy.

Nickel(II) ion (which has eight *d* electrons) forms a complex with cyanide ion that is square planar and diamagnetic. In this complex the strong field produced by the cyanide ions yields a large energy separation between the d_{xy} and $d_{x^2-y^2}$ orbitals, so that a low-spin complex results. The electron distribution in this complex is illustrated in Figure 22.23.

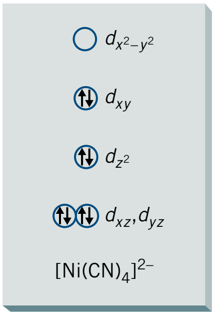

Figure 22.23 | **Distribution of the electrons among the *d* orbitals of nickel in the diamagnetic $[Ni(CN)_4]^{2-}$ ion.**

Tetrahedral Complexes

The splitting pattern for the *d* orbitals in a tetrahedral complex is illustrated in Figure 22.24. Now, the ligands are approaching the metal center between the axes, so the order of the energy levels is exactly opposite to that in an octahedral complex. In addition, the size of the crystal field splitting, Δ, is also much smaller for a tetrahedral complex than for an octahedral one. (Actually, $\Delta_{tet} \approx \frac{4}{9}\Delta_{oct}$ for the same metal ion with the same ligands.) This small Δ is always less than the pairing energy, so tetrahedral complexes are always high-spin complexes.

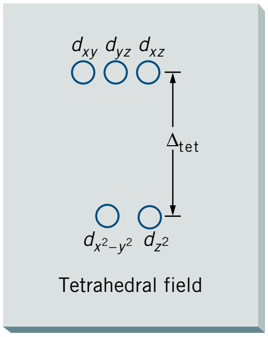

Figure 22.24 | **Splitting pattern of the *d* orbitals for a tetrahedral complex.** The crystal field splitting for the tetrahedral structure (Δ_{tet}) is smaller than that for the octahedral structure (Δ_{oct}). For complexes with the same ligands, $\Delta_{tet} \approx \frac{4}{9}\Delta_{oct}$.

22.6 | Biological Functions of Metal Ions

Most of the compounds in our bodies have structures based on carbon as the principal element, and their functions are usually related to the geometries assumed by carbon-containing compounds, as well as the breaking and forming of carbon–carbon, carbon–hydrogen, carbon–oxygen, and carbon–nitrogen bonds. In Chapter 23 we will discuss some classes of biochemical molecules.

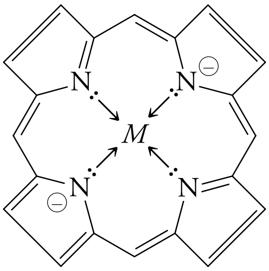
Our bodies also require certain metal ions in order to operate, and without them life cannot be sustained. For this reason, the study of metals in biological systems has become a very important branch of biochemistry, and a large number of research papers are published annually that deal with this topic. Table 22.3 lists some of the essential metals and the functions fulfilled by their ions.

A few metals, such as sodium and potassium, are found as simple monatomic ions in body fluids. Most metal ions, however, become bound by ligands and do their work as part of metal complexes. As examples, we will look briefly at two metals—iron and cobalt.

Table 22.3 **Some Biologically Important Metals and the Corresponding Human Body Functions with which Their Ions Are Involved**

Metal	Body Function
Na, Ca	Blood pressure and blood coagulation
Fe	Oxygen transport and storage
Ca	Teeth and bone formation
Ca	Urinary stone formation
Zn	Control of pH in blood
Ca, Mg	Muscle contraction
K	Maintenance of stomach acidity
Fe, Cu	Respiration
Cu	Bone health
Ca, Fe, Co	Cell division

Iron is one of the essential elements required by our bodies. We obtain it in a variety of ways in our diets. Iron is involved in oxygen transport in our blood and in retaining oxygen in muscle tissue so that it's available when needed. The iron is present as Fe^{2+} held in a complex in which the basic ligand structure is



This ligand composition, with its square planar arrangement of nitrogen atoms that bind to a metal ion, is called a *porphyrin structure*. It is the ligand structure in a biologically active unit called heme. Heme is the oxygen-carrying component of the blood protein hemoglobin and in myoglobin, which is found in muscle tissue.

In the lungs, O_2 molecules are absorbed by the blood and become bound to Fe^{2+} ions in the heme units of hemoglobin (Figure 22.25). Blood circulation then carries the O_2 to tissues where it is needed, at which time it is released by the Fe^{2+}. One of the important functions of the porphyrin ligand in this process is to prevent the Fe^{2+} from being oxidized by the O_2. (In fact, if the iron is oxidized to Fe^{3+}, it is no longer able to carry O_2.) In muscle tissue, heme units in the protein myoglobin take O_2 from hemoglobin and hold it until it's needed. In this way, muscle tissue is able to store O_2 so that plenty of it is available when the muscle must work hard.

Heme units are also present in proteins called cytochromes, where the iron is involved in electron transfer reactions that employ the +2 and +3 oxidation states of iron.

- The porphyrin structure is present in chlorophyll too, where the metal bound in the center is Mg^{2+}. Chlorophyll absorbs sunlight (solar energy) which is used by plants to convert carbon dioxide and water into glucose and oxygen.

- The iron in hemoglobin also binds CO_2 and helps transport it back to the lungs to be exhaled.

- The ability of transition metals to exist in different oxidation states is one reason they are used in biological systems. They can easily take part in oxidation–reduction reactions. Copper(I) and copper(II) ions constitute another pair involved in catalyzing biochemical redox reactions.

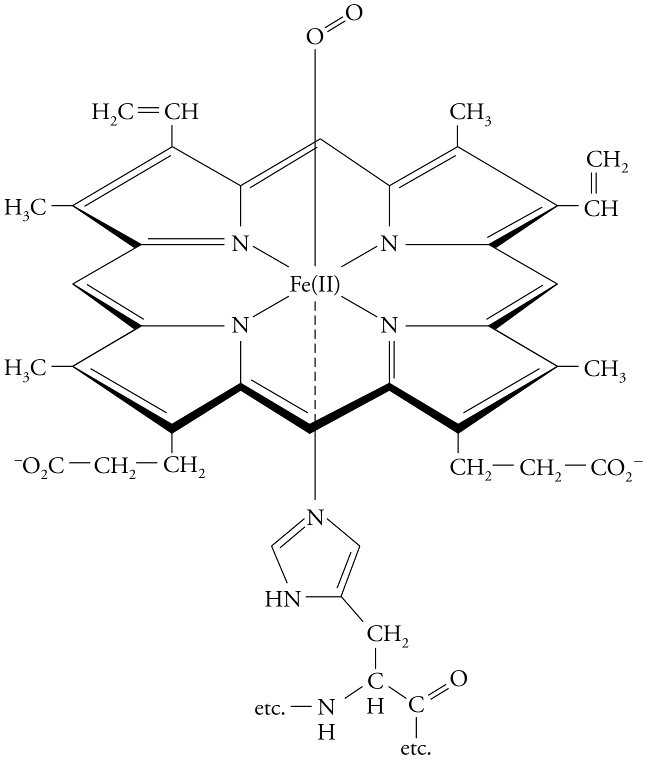


Figure 22.25 | **Iron(II) bound to oxygen in heme.** The porphyrin ring ligand in heme surrounds an Fe^{2+} ion that binds an O_2 molecule. In its oxygenated form, the Fe^{2+} is octahedrally coordinated in the structure.

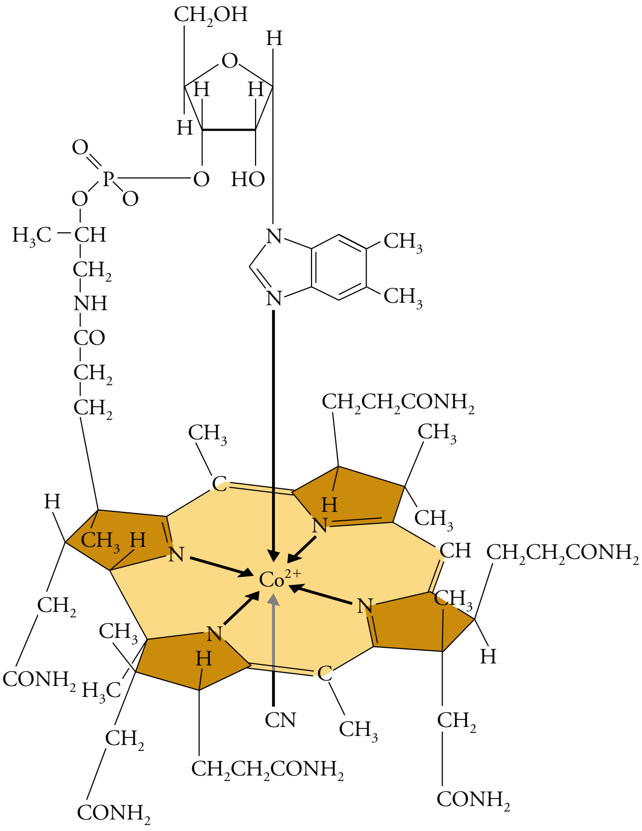


Vitamin B_{12}

Figure 22.26 | **The structure of cyanocobalamin.** Notice the cobalt ion in the center of the square planar arrangement of nitrogen atoms that are part of the ligand structure. Overall, the cobalt is surrounded octahedrally by donor atoms.

A structure similar to heme is found in cyanocobalamin, the form of vitamin B_{12} found in vitamin pills (Figure 22.26). Here, a Co^{2+} ion is held in a square planar ligand structure (called a *corrin ring*) that is slightly different from that found in heme. Certain enzymes (biological catalysts) require cobalamins to function. Vitamin B_{12} is essential in our diets, and a deficiency in this vitamin leads to a disease called pernicious anemia.

We have illustrated here just a few examples of the important roles that metal ions play in living systems. They are roles that cannot be fulfilled by other carbon-based compounds, some of which are described in Chapter 23.

Summary

Complex Ions of Metals. **Coordination compounds** contain **complex ions** (also called **complexes** or **coordination complexes**), formed from a metal ion and a number of ligands. **Ligands** are Lewis bases and may be **monodentate**, **bidentate**, or, in general, **polydentate**, depending on the number of **donor atoms** that they contain. Water is the most common monodentate ligand. Polydentate ligands bind to a metal through two or more donor atoms and yield ring structures called **chelates**. Common bidentate ligands are oxalate ion and ethylenediamine (en); a common polydentate ligand is ethylenediaminetetraacetic acid (EDTA), which has six donor atoms.

In the formula of a complex, the metal is written first, followed by the formulas of the ligands (anions first, in alphabetical order, followed by neutral ligands, in alphabetical order). Brackets are used to enclose the set of atoms that make up the complex, with the charge on the complex written outside the brackets. The charge on the complex is the algebraic sum of the charges on the metal ion and the charges on the ligands.

Complexes of polydentate ligands are more stable than similar complexes formed with monodentate ligands, partly because a polydentate ligand is less likely to be lost completely if one of its donor atoms becomes detached from the metal ion. The larger positive entropy change for the dissociation of complexes with monodentate ligands also favors their dissociation compared with complexes of polydentate ligands. The phenomenon is called the **chelate effect**.

Nomenclature of Complexes. Complexes are named following a set of rules developed by the IUPAC. These are summarized on pages 1023 to 1024.

Coordination Number and Structure. The **coordination number** of a metal ion in a complex is the number of donor atoms attached to the metal ion. Polydentate ligands supply two or more donor atoms, which must be taken into account when determining the coordination number from the formula of the complex. Geometries associated with common coordination numbers are as follows: for coordination number 2, linear; for coordination number 4, tetrahedral and square planar (especially for Pt^{2+} complexes); and for coordination number 6, octahedral.

Isomers of Coordination Compounds. When two or more distinct compounds have the same chemical formula, they are **isomers** of each other. **Stereoisomers** have the same atoms attached to each other, but the atoms are arranged differently in space. In a ***cis* isomer**, attached groups of atoms are on the same side of some reference plane through the molecule. In a ***trans* isomer**, they are on opposite sides. *Cis* and *trans* isomerism is a form of **geometric isomerism. Chiral** isomers are exactly the same in every way but one—they are not superimposable on their mirror images. These kinds of isomers exist for complexes of the type $M(AA)_3$, where M is a metal ion and AA is a bidentate ligand, and also for complexes of the type *cis*-$M(AA)_2a_2$, where a is a monodentate ligand. Chiral isomers that are mirror images of each other are said to be **enantiomers**. Because they are able to rotate **plane-polarized light**, they are called **optical isomers**.

Crystal Field Theory. In an octahedral complex, the ligands influence the energies of the *d* orbitals by splitting the *d* subshell into two energy sublevels. The lower-energy one consists of the d_{xy}, d_{xz}, and d_{yz} orbitals; the higher-energy level consists of the d_{z^2} and $d_{x^2-y^2}$ orbitals. The energy difference between the two new *d* sublevels is the **crystal field splitting**, Δ, and for a given ligand it increases with an increase in the oxidation state of the metal and it depends on the period number in which the metal is found. For a given metal ion, Δ depends on the ligand.

In the **spectrochemical series**, ligands are arranged in order of their ability to cause a large Δ. Cyanide ion produces the largest crystal field splitting, whereas iodide ion produces the smallest. **Low-spin** complexes result when Δ is larger than the **pairing energy**—the energy needed to cause two electrons to become paired in the same orbital. **High-spin** complexes occur when Δ is smaller than the pairing energy. Light of energy equal to Δ is absorbed when an electron is raised from the lower-energy set of *d* orbitals to the higher set, and the color of the complex is determined by the colors that remain in the transmitted light. Crystal field theory can also explain the relative stabilities of oxidation states, in many cases.

Different splitting patterns of the *d* orbitals occur for other geometries. The patterns for square planar and tetrahedral geometries are described in Figures 22.22 and 22.24, respectively. The value of Δ for a tetrahedral complex is only about 4/9 that of Δ for an octahedral complex.

Metals in Living Systems. Most metals required by living organisms perform their actions when bound as complex ions. Heme contains Fe^{2+} held in a square planar porphyrin ligand and binds to O_2 in hemoglobin and myoglobin. Heme is also found in cytochromes, where it participates in redox reactions involving Fe^{2+} and Fe^{3+}. Vitamin B_{12}, required by the body to prevent the vitamin deficiency disease called pernicious anemia, contains Co^{2+} in a corrin ring structure, which is similar to the porphyrin ring.

Tools for Problem Solving

The following tools were introduced in this chapter. Study them carefully so you can select the appropriate tool when needed.

Rules for writing formulas for complexes (page 1020)

The following rules apply whenever you have to write the formula for a complex ion:

1. The symbol for the metal ion is always given first, followed by the ligands.
2. When more than one kind of ligand is present, anionic ligands are written first (in alphabetical order), followed by neutral ligands (also in alphabetical order).
3. The charge on the complex is the algebraic sum of the charge on the metal ion and the charges on the ligands.

Rules for naming complexes (pages 1023 to 1024)

Naming complexes follows rules that are an extension of the rules you learned earlier. You have to learn them and then apply them when you have to name a complex or write a formula given the name.

Crystal field splitting pattern for octahedral complexes (page 1033)

Figure 22.15 forms the basis for applying the principles of crystal field theory to octahedral complexes. To use it, you need the electron configuration of the metal ion. First, write the electron configuration for the metal under consideration. Then, remove electrons from the atom starting with the outer *s* subshell first, followed if necessary by electrons from the underlying *d* subshell. For a complex under consideration, set up the splitting diagram and place electrons into the *d* orbitals following Hund's rule. For d^4, d^5, d^6, and d^7 configurations, you may have to decide whether a high- or low-spin configuration is preferred.

Spectrochemical series (page 1036)

Use the location of ligands in the spectrochemical series to compare their effects on the crystal field splitting. The series is

$$\mathrm{CN^-} > \mathrm{NO_2^-} > \mathrm{en} > \mathrm{NH_3} > \mathrm{H_2O} > \mathrm{C_2O_4^{2-}} > \mathrm{OH^-} > \mathrm{F^-} > \mathrm{Cl^-} > \mathrm{Br^-} > \mathrm{I^-}$$

PLUS = *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com.** **ILW** = An Interactive Learningware solution is available for this problem. **OH** = An Office Hour video is available for this problem. Review Problems are presented in pairs separated by blue rules. Answers to problems whose numbers appear in blue are given in Appendix B. More challenging problems are marked with an asterisk *.

Review Questions

Complex Ions

22.1 The formation of the complex ion $[\mathrm{Cu(H_2O)_6}]^{2+}$ is described as a Lewis acid–base reaction. Explain.

- **(a)** What are the formulas of the Lewis acid and the Lewis base in this reaction?
- **(b)** What is the formula of the ligand?
- **(c)** What is the name of the species that provides the donor atom?
- **(d)** What atom is the donor atom, and why is it so designated?
- **(e)** What is the name of the species that is the acceptor?

22.2 To be a ligand, a substance should also be a Lewis base. Explain.

22.3 Why are substances that contain complex ions often called coordination compounds?

22.4 Use Lewis structures to diagram the formation of $\mathrm{Cu(NH_3)_4}^{2+}$ and $\mathrm{CuCl_4}^{2-}$ ions from their respective components.

22.5 What must be true about the structure of a ligand classified as *bidentate*?

22.6 What is a *chelate*? Use Lewis structures to diagram the way that the oxalate ion, $\mathrm{C_2O_4}^{2-}$, functions as a chelating agent.

22.7 How many donor atoms does $\mathrm{EDTA^{4-}}$ have?

22.8 Explain how a salt of $\mathrm{EDTA^{4-}}$ can retard the spoilage of salad dressing.

22.9 How does a salt of $\mathrm{EDTA^{4-}}$ in shampoo make the shampoo work better in hard water?

22.10 The cobalt(III) ion, $\mathrm{Co^{3+}}$, forms a 1:1 complex with $\mathrm{EDTA^{4-}}$. What is the net charge, if any, on this complex, and what would be a suitable formula for it (using the symbol EDTA)?

22.11 Which complex is more stable, $[\mathrm{Cr(NH_3)_6}]^{3+}$ or $[\mathrm{Cr(en)_3}]^{3+}$? Why?

Coordination Number and Structure

22.12 What is a *coordination number*? What structures are generally observed for complexes in which the central metal ion has a coordination number of 4? What is the most common structure observed for coordination number 6?

22.13 Sketch the structure of an octahedral complex that contains only identical monodentate ligands. Use *M* for the metal and *L* for the ligand.

22.14 Sketch the structure of the octahedral $[\mathrm{Co(EDTA)}]^-$ ion. Remember that adjacent donor atoms in a polydentate ligand span adjacent positions in the octahedron.

Isomers of Coordination Compounds

22.15 What are *isomers*?

22.16 Define *stereoisomerism*, *geometric isomerism*, *chiral isomers*, and *enantiomers*.

22.17 What are *cis* and *trans isomers*?

22.18 What condition must be fulfilled in order for a molecule or ion to be chiral?

22.19 What are optical isomers?

22.20 What are the differences between optical and geometric isomers?

Bonding in Complexes

22.21 On appropriate coordinate axes, sketch and label the five *d* orbitals.

22.22 Which *d* orbitals point *between* the *x*, *y*, and *z* axes? Which point *along* the coordinate axes?

22.23 Explain why an electron in a $d_{x^2-y^2}$ or d_{z^2} orbital in an octahedral complex will experience greater repulsions because of the presence of the ligands than an electron in a d_{xy}, d_{xz}, or d_{yz} orbital.

22.24 Sketch the *d*-orbital energy level diagram for a typical octahedral complex.

22.25 Explain why octahedral cobalt(II) complexes are easily oxidized to cobalt(III) complexes. Sketch the *d*-orbital energy diagram and assume a large value of Δ when placing electrons in the *d* orbitals.

22.26 Explain how the same metal in the same oxidation state is able to form complexes of different colors.

22.27 If a complex appears red, what color light does it absorb? What color light is absorbed if the complex appears yellow?

22.28 What does the term *spectrochemical series* mean? How can the order of the ligands in the series be determined?

22.29 What do the terms *low-spin complex* and *high-spin complex* mean?

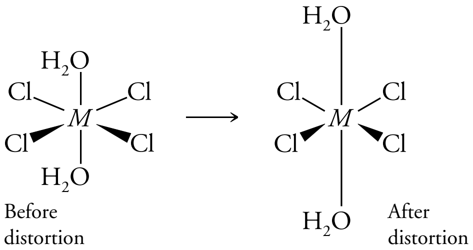
22.30 For which *d*-orbital electron configurations are both high-spin and low-spin octahedral complexes possible?

22.31 What factors about the metal and ligands affect the magnitude of Δ?

22.32 Indicate by means of a sketch what happens to the *d*-orbital electron configuration of the $[Fe(CN)_6]^{4-}$ ion when it absorbs a photon of visible light.

22.33 The complex $[Co(C_2O_4)_3]^{3-}$ is diamagnetic. Sketch the *d*-orbital energy level diagram for this complex and indicate the electron populations of the orbitals.

22.34 Consider the complex $[M(H_2O)_2Cl_4]^-$ illustrated below on the left. Suppose the structure of this complex is distorted to give the structure on the right, where the water molecules along the *z* axis have moved away from the metal somewhat and the four chloride ions along the *x* and *y* axes have moved closer. What effect will this distortion have on the energy level splitting pattern of the *d* orbitals? Use a sketch of the splitting pattern to illustrate your answer.



Before distortion

After distortion

Biological Functions of Metals Ions

22.35 In what ways is the porphyrin structure important in biological systems?

22.36 If a metal ion is held in the center of a porphyrin ring structure, what is its coordination number? (Assume the porphyrin is the only ligand.)

22.37 What function does heme serve in hemoglobin? What does it do in myoglobin?

22.38 How are the ligand ring structures similar in vitamin B_{12} and in heme? What metal is coordinated in cobalamin?

22.39 What are some of the roles played by calcium ion in the body?

Review Problems

Complex Ions

22.40 The iron(III) ion forms a complex with six cyanide ions that is often called the ferricyanide ion. What is the net charge on this complex ion, and what is its formula? What is the IUPAC name for the complex?

22.41 The silver ion forms a complex ion with two ammonia molecules. What is the formula of this ion, and what is its IUPAC name? Can this complex ion exist as a salt with the sodium ion or with the chloride ion? Write the formula of the possible salt. (Use brackets and parentheses correctly.)

22.42 Write the formula, including its correct charge, for a complex that contains Co^{3+}, two Cl^-, and two ethylenediamine ligands.

OH **22.43** Write the formula, including its correct charge, for a complex that contains Cr^{3+}, two NH_3 ligands, and four NO_2^- ligands.

Metal Complex Nomenclature

22.44 How would the following molecules or ions be named as ligands when writing the name of a complex ion?

(a) $C_2O_4^{2-}$ **(b)** S^{2-} **(c)** Cl^-

(d) $(CH_3)_2NH$ (dimethylamine)

OH **22.45** How would the following molecules or ions be named as ligands when writing the name of a complex ion?

(a) NH_3 **(b)** N^{3-} **(c)** SO_4^{2-} **(d)** $C_2H_3O_2^-$

22.46 Give IUPAC names for each of the following:

(a) $[Ni(NH_3)_6]Cl_2$

(b) $[CrCl_3(NH_3)_3]^-$

(c) $[Co(NO_2)_6]^{3-}$

(d) $[Mn(CN)_4(NH_3)_2]^{2-}$

(e) $K_3[Fe(C_2O_4)_3]$

22.47 Give IUPAC names for each of the following:

- **(a)** $[AgI_2]^-$
- **(b)** $[SnS_3]^{2-}$
- **(c)** $[Co(en)_2(H_2O)_4]_2(SO_4)_3$
- **(d)** $[CrCl(NH_3)_5]SO_4$
- **(e)** $K_3[Co(C_2O_4)_3]$

22.48 Write chemical formulas for each of the following:

- **(a)** tetraaquadicyanoiron(III) ion
- **(b)** tetraammineoxalatonickel(II)
- **(c)** pentaaquahydroxoaluminum(III) chloride
- **(d)** potassium hexathiocyanatomanganate(III)
- **(e)** tetrachlorocuprate(II) ion

22.49 Write chemical formulas for each of the following:

- **(a)** tetrachloroaurate(III) ion
- **(b)** bis(ethylenediamine)dinitroiron(III) ion
- **(c)** tetraamminedicarbonatocobalt(III) nitrate
- **(d)** ethylenediaminetetraacetatoferrate(II) ion
- **(e)** diamminedichloroplatinum(II)

Coordination Number and Structure

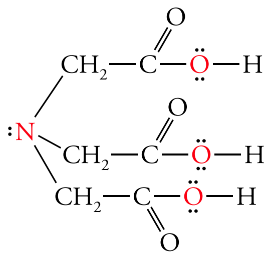
22.50 What is the coordination number of Fe in $[FeCl_2(H_2O)_2(en)]$? What is the oxidation number of iron in this complex?

OH **22.51** What is the coordination number of nickel in $[Ni(C_2O_4)_2(NO_2)_2]^{4-}$?

22.52 Draw a reasonable structure for **(a)** $[Zn(NH_3)_4]^{2+}$ and **(b)** trioxalatochromate(III) ion.

22.53 Draw a reasonable structure for **(a)** $[CoBr(NH_3)_3]^{2+}$ and **(b)** dichloroethylenediamineplatinum(II).

22.54 NTA is the abbreviation for nitrilotriacetic acid, a substance that was used at one time in detergents. Its structure is



The four donor atoms of this ligand are shown in red. Sketch the structure of an octahedral complex containing this ligand. Assume that two water molecules are also attached to the metal ion and that each oxygen donor atom in the NTA is bonded to a position in the octahedron that is adjacent to the nitrogen of the NTA.

22.55 The following compound is called diethylenetriamine and is abbreviated "dien":

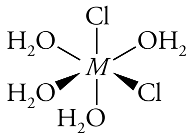
$$H_2\ddot{N}-CH_2-CH_2-\ddot{N}H-CH_2-CH_2-\ddot{N}H_2$$

When it bonds to a metal, it is a ligand with three donor atoms.

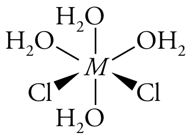
- **(a)** Which are most likely the donor atoms?
- **(b)** What is the coordination number of cobalt in the complex $Co(dien)_2{}^{3+}$?
- **(c)** Sketch the structure of the complex $[Co(dien)_2]^{3+}$.
- **(d)** Which complex would be expected to be more stable in aqueous solution, $[Co(dien)_2]^{3+}$ or $[Co(NH_3)_6]^{3+}$?
- **(e)** What would be the structure of triethylenetetraamine?

Isomers of Metal Complexes

22.56 Below are two structures drawn for a complex. Are they actually different isomers, or are they identical? Explain your answer.

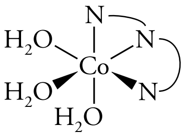


Structure I



Structure II

***22.57** Below is a structure for one of the isomers of the complex $[Co(H_2O)_3(dien)]^{3+}$. Are isomers of this complex chiral? Justify your answer. See Problem 22.55.



$N\frown N\frown N$ represents dien

22.58 Sketch and label the isomers of the square planar complex $[PtBrCl(NH_3)_2]$.

22.59 The complex $[CoCl_3(NH_3)_3]$ can exist in two isomeric forms. Sketch them.

22.60 Sketch the chiral isomers of $[Co(C_2O_4)_3]^{3-}$.

OH **22.61** Sketch the chiral isomers of $[CrCl_2(en)_2]^+$. Is there a nonchiral isomer of this complex?

Bonding in Metal Complexes

22.62 In which complex do we expect to find the larger Δ?

- **(a)** $[Cr(H_2O)_6]^{2+}$ or $[Cr(H_2O)_6]^{3+}$
- **(b)** $[Cr(en)_3]^{3+}$ or $[CrCl_6]^{3-}$

22.63 Arrange the following complexes in order of increasing wavelength of the light absorbed by them: $[Cr(H_2O)_6]^{3+}$, $[CrCl_6]^{3-}$, $[Cr(en)_3]^{3+}$, $[Cr(CN)_6]^{3-}$, $[Cr(NO_2)_6]^{3-}$, $[CrF_6]^{3-}$, and $[Cr(NH_3)_6]^{3+}$.

OH **22.64** Which complex should be expected to absorb light of the highest frequency, $[Cr(H_2O)_6]^{3+}$, $[Cr(en)_3]^{3+}$, or $[Cr(CN)_6]^{3-}$?

22.65 Which complex should absorb light at the longer wavelength?

(a) $[Fe(H_2O)_6]^{2+}$ or $[Fe(CN)_6]^{4-}$

(b) $[Mn(CN)_6]^{3-}$ or $[Mn(CN)_6]^{4-}$

22.66 In each pair below, which complex is expected to absorb light of the shorter wavelength? Justify your answers.

(a) $[RuCl(NH_3)_5]^{2+}$ or $[FeCl(NH_3)_5]^{2+}$

(b) $[Ru(NH_3)_6]^{2+}$ or $[Ru(NH_3)_6]^{3+}$

22.67 A complex $[CoA_6]^{3+}$ is red. The complex $[CoB_6]^{3+}$ is green. Which ligand, A or B, produces the larger crystal field splitting, Δ? Explain your answer.

22.68 Referring to the two ligands, A and B, described in Problem 22.67, which complex would be expected to be more easily oxidized, $[CoA_6]^{2+}$ or $[CoB_6]^{2+}$? Explain your answer.

22.69 Referring to the complexes in Problems 22.67 and 22.68, would the color of $[CoA_6]^{2+}$ more likely be red or blue?

22.70 Would the complex $[CoF_6]^{4-}$ more likely be low-spin or high-spin? Could it be diamagnetic?

22.71 Sketch the *d*-orbital energy level diagrams for $[Fe(H_2O)_6]^{3+}$ and $[Fe(CN)_6]^{3-}$ and predict the number of unpaired electrons in each.

Additional Exercises

22.72 Ni^{2+} ions can be either four coordinate or six coordinate; which one is more likely to be a red compound and which is likely to be a blue compound?

22.73 For the complex $(NH_4)_2[Pd(SCN)_4]$, draw the structure of the free ligand, draw the structure of the complex, indicate the shape of the complex, and give the oxidation state of the central metal ion.

22.74 Most of the first row transition metals form 2+ ions, while other oxidation states are less common. Why do these metals form 2+ ions?

22.75 Is the complex $[Co(EDTA)]^-$ chiral? Illustrate your answer with sketches.

22.76 The complex $[PtCl_2(NH_3)_2]$ can be obtained as two distinct isomeric forms. Make a model of a tetrahedron and show that if the complex were tetrahedral, two isomers would be impossible.

22.77 $[Ag(NH_3)_2]^+$ and $[Ag(CN)_2]^-$ are both linear complexes. Draw the crystal field energy level diagram for the *d*-orbitals for a linear complex, if the ligands lie along the *z* axis.

OH ***22.78** A solution was prepared by dissolving 0.500 g of $CrCl_3 \cdot 6H_2O$ in 100 mL of water. A silver nitrate solution was added and gave a precipitate of AgCl that was filtered from the mixture, washed, dried, and weighed. The AgCl had a mass of 0.538 g.

(a) What is the formula of the complex ion of chromium in this compound?

(b) What is the correct formula for the compound?

(c) Sketch the structure of the complex ion in this compound.

(d) How many different isomers of the complex can be drawn?

***22.79** The compound $Cr_2(NH_3)_3(H_2O)_3Cl_6$ is a neutral salt in which the cation and anion are both octahedral complex ions. How many isomers (including possible structural and chiral isomers) are there that have this overall composition?

***22.80** The complex $[Co(CN)_6]^{4-}$ is not expected to be perfectly octahedral. Instead, the ligands in the *xy* plane are pulled closer to the Co^{2+} ion while those along the *z* axis move slightly farther away. Using information available in this chapter, explain why the distortion of the octahedral geometry leads to a net lowering of the energy of this complex.

22.81 Sketch all of the isomers of $[CoCl_2(en)(NH_3)_2]^+$. Label the *cis* chloro and *trans* chloro isomers.

22.82 Copper(II) aqueous solutions are blue and zinc(II) aqueous solutions are colorless. Why?

Multi-Concept Problems

22.83 Silver plating processes often use $Ag(CN)_2^-$ as the source for Ag^+ in solution. To make the solution, a chemist used 4.0 L of 3.00 *M* NaCN and 50 L of 0.2 *M* $AgNO_3$. What is the concentration of free Ag^+ ions? Why is AgCl not used in this process?

***22.84** Cobalt forms complexes in both the +2 and +3 oxidation states. The standard reduction potential for Co^{3+} to Co^{2+} is 1.82 V. In water, the species in solution is $[Co(H_2O)_6]^{3+}$. The equilibrium constants for the formation of the hexaammine complexes are as follows:

$$Co^{2+} + 6NH_3 \rightleftharpoons [Co(NH_3)_6]^{2+} \qquad K_{form} = 1.3 \times 10^{14}$$

$$Co^{3+} + 6NH_3 \rightleftharpoons [Co(NH_3)_6]^{3+} \qquad K_{form} = 4.8 \times 10^{48}$$

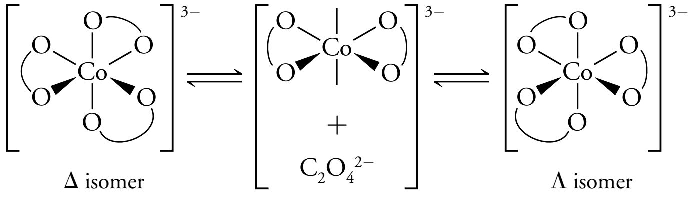
Why is the cobalt(III) complex more stable than the cobalt(II) species? What is the reduction potential for the reduction of $[Co(NH_3)_6]^{3+}$? Which is a stronger oxidizing agent, $[Co(NH_3)_6]^{3+}$ or $[Co(H_2O)_6]^{3+}$?

***22.85** Platinum(IV) makes compounds with coordination numbers of 6. A Pt^{4+} compound was made with chloride and amine ligands. The empirical formula for the compound was determined to be $PtCl_4(NH_3)_6$. The isolated compound has an osmotic pressure of 0.734 atm for a 0.1 *M* solution, and when 0.126 g of the compound was reacted with $AgNO_3$, 0.0209 g of AgCl was formed. How many ions does the compound form in water? What is the structure of this compound? What other isomers could have been formed? How many ions would they have released in solution?

Exercises in Critical Thinking

22.86 It was mentioned in footnote 5 on page 456 that *d* orbitals are capable of participating in the formation of π bonds. Make a sketch that illustrates how such a bond could be formed between two *d* orbitals and between a *d* and a *p* orbital.

22.87 The two chiral isomers of $[Co(C_2O_4)_3]^{3-}$ (shown at the right) can be viewed as propellers having either a right- or left-handed twist, respectively. They are identified by the labels Δ and Λ, as indicated. A 50–50 mixture of both isomers is said to be *racemic* and will not rotate plane polarized light. Using various laboratory procedures, the two isomers present in a racemic mixture can be separated from each other. For this complex, however, a solution of a single isomer is unstable and gradually reverts to a mixture of the two isomers by a process called *racemization*. Racemization involves the conversion of one isomer to the other until an equilibrium between the two isomers is achieved (i.e., $\Delta \rightleftharpoons \Lambda$). One mechanism proposed for the racemization of the isomers of $[Co(C_2O_4)_3]^{3-}$ involves the dissociation of an oxalate ion followed by the rearrangement and then the reattachment of $C_2O_4^{2-}$.



What experiment could you perform to test whether this is really the mechanism responsible for the racemization of $[Co(C_2O_4)_3]^{3-}$?

23 Organic Compounds, Polymers, and Biochemicals

Chapter Outline

23.1 | The Nature of Organic Chemistry

23.2 | Hydrocarbons

23.3 | Organic Compounds Containing Oxygen

23.4 | Organic Derivatives of Ammonia

23.5 | Organic Polymers

23.6 | Biochemical Compounds

23.7 | Nucleic Acids

It's difficult to find anyone who has not watched at least one of the CSI crime shows. Crime scene investigators gather evidence of various kinds, including samples of human tissue and bodily fluids. As is well known now, such samples can be subjected to DNA analysis, and a match between a crime scene sample and a suspect is very convincing evidence that the suspect was involved in some way with the crime. This is because a person's DNA differs from that of all other individuals on earth (except if the person has an identical twin). DNA is what makes us unique and is one of the biochemical compounds discussed in this chapter. Robert Prezioso/Getty Images, Inc.

This Chapter in Context

In Section 9.6 we noted that many of the substances we encounter on a daily basis have molecular structures based on atoms of carbon linked to one another by covalent bonds. You've already seen a variety of them as examples used in discussions throughout this book. They include such substances as hydrocarbons, alcohols, ketones (such as acetone), and organic acids. The number of such compounds is enormous and their study constitutes the branch of chemistry called *organic chemistry*, so named because at one time it was believed that such substances could only be synthesized by living organisms.

At the molecular level of life, nature uses compounds of carbon. The amazing variety of living systems, down to the uniqueness of each individual, is possible largely because of the properties of this element. We'll take a look at some biologically important kinds of carbon compounds near the end of this chapter.

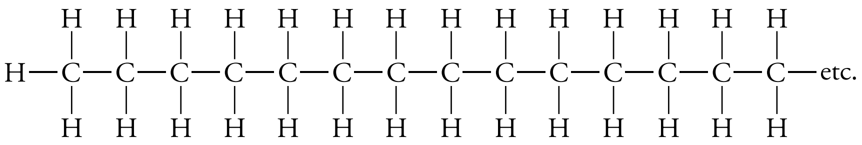
23.1 | The Nature of Organic Chemistry

Organic chemistry is the study of the preparation, properties, and reactions of those compounds of carbon not classified as inorganic. The latter include the oxides of carbon, the bicarbonates and carbonates of metal ions, the metal cyanides, and a handful of other compounds. There are tens of millions of known carbon compounds, and all but a very few are classified as organic.

Uniqueness of the Element Carbon

■ Sulfur atoms can also form long chains, but they are unable to bond to the atoms of any other element strongly at the same time.

What makes the existence of so many organic compounds possible is the ability of carbon atoms to form strong covalent bonds to each other *while at the same time bonding strongly to atoms of other nonmetals*. For example, molecules in the plastic polyethylene have *carbon chains* that are thousands of carbon atoms long, with hydrogen atoms attached to each carbon.



$$\mathrm{H}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\underset{\mathrm{H}}{\overset{\mathrm{H}}{\mathrm{C}}}-\text{etc.}$$

polyethylene (small segment of one molecule)

The longest known sequence of atoms of the other members of Group 4A, each also bonded to hydrogen atoms, is eight for silicon, five for germanium, two for tin, and one for lead.

■ The isomers of butane were also discussed on page 373.

Another reason for the huge number of organic compounds is *isomerism*, which was mentioned briefly in Chapter 9 on page 374. (Isomerism among complex ions is discussed in Chapter 22.) Recall that *isomers* are compounds with identical molecular formulas, but whose molecules have different structures. There are a number of different kinds of isomers, as we will discuss below. Two examples of isomers of C_4H_{10} and of C_2H_6O are shown in Figure 23.1. Notice the tetrahedral arrangement of atoms around each of the carbon atoms. This tetrahedral geometry is found whenever carbon is bonded to other atoms by just single bonds.

The structural formulas of the compounds in Figure 23.1 can be represented in different ways. Complete Lewis structures can be drawn showing all of the bonds between atoms.

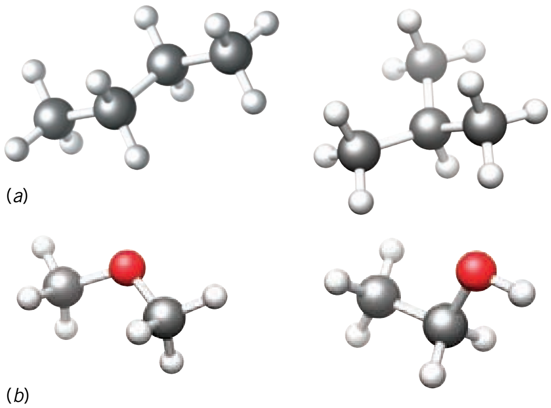


Figure 23.1 | **Isomers.** (*a*) The isomers of C_4H_{10}. Butane is on the left and methylpropane (isobutane) is on the right. (*b*) The isomers of C_2H_6O. Dimethyl ether is on the left and ethanol is on the right.

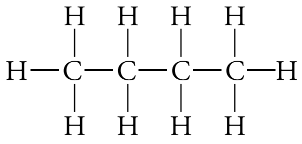
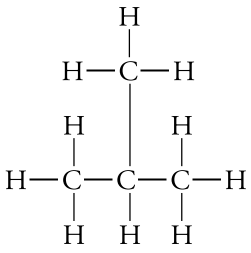
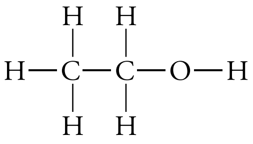


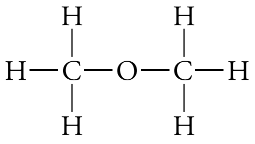
butane
BP −0.5 °C



2-methylpropane
(isobutane)
BP −11.7 °C



ethanol
BP 78.5 °C



dimethyl ether
BP −23 °C

Notice that each isomer has a different boiling point. As we noted in Chapter 9, isomers are different chemical substances, each with its own set of properties.

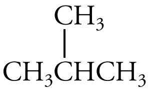
To save space and time when writing structural formulas we can write **condensed structural formulas** (also called **condensed structures**) such as those below, in which the C—H, C—C, and C—O bonds are "understood." We can do this because in nearly all organic compounds carbon forms four bonds, nitrogen forms three, oxygen forms two, and hydrogen forms one.

■ VSEPR theory permits us to predict the tetrahedral geometry around carbon observed in Figure 23.1.

TOOLS

Condensed structures

$CH_3CH_2CH_2CH_3$
butane



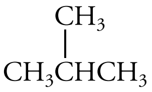
$CH_3\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_3$

methylpropane
(isobutane)

CH_3CH_2OH
ethanol

CH_3OCH_3
dimethyl ether

Take a moment to compare the condensed structural formulas with the full Lewis structures. Also note that there can be more than one way to write a condensed structure, as illustrated by 2-methylpropane.



$CH_3\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_3$ or $CH_3CH(CH_3)CH_3$ or $(CH_3)_3CH$

We will use condensed structures frequently throughout this chapter. *In writing condensed structures, be sure there are sufficient numbers of hydrogens so that the total number of bonds to each carbon equals four.*

In Chapter 22 we described the chiral properties of certain isomers. An organic compound exhibits chirality when it contains an **asymmetric carbon atom,** which is a carbon atom that is bonded to four different atoms or groups. An example is butan-2-ol (also called

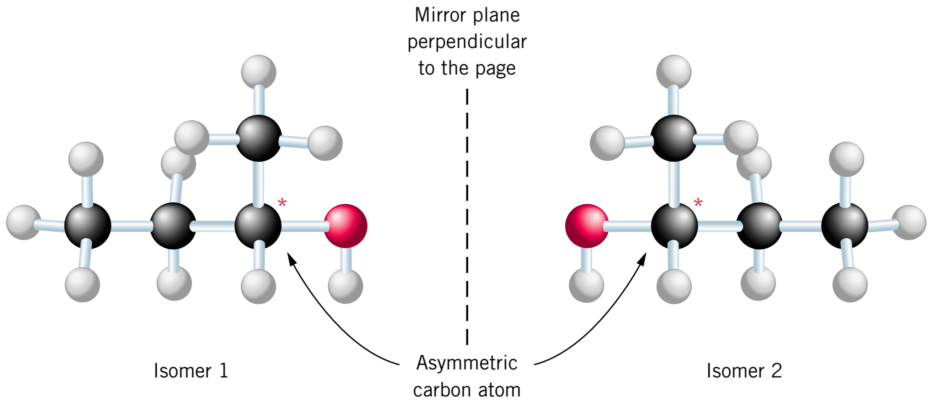


Figure 23.2 | **Chiral isomers of butan-2-ol.** Isomer 2 is the mirror image of Isomer 1. No matter how you twist or turn Isomer 1, you cannot get it to fit exactly onto Isomer 2, which means the two isomers are nonsuperimposable mirror images of each other.

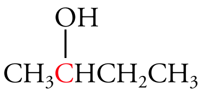
2-butanol) in which the asymmetric carbon atom, marked with a red asterisk, is bonded to H, OH, CH_3, and CH_2CH_3.



$$CH_3\overset{\overset{OH}{|}}{C}HCH_2CH_3$$

butan-2-ol
2-butanol

The two nonsuperimposable mirror image isomers of this compound, also called optical isomers or stereoisomers, are shown in Figure 23.2.

The table in the margin illustrates that as the number of carbons per molecule increases, the number of possible isomers for any given formula becomes enormous.

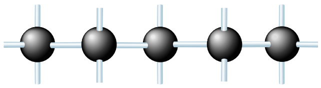
■ Few of the possible isomers of the compounds with large numbers of carbon atoms have actually been made, but there is nothing except too much crowding within the molecules of some of them to prevent their existence.

Formula	**Number of Isomers**
C_8H_{18}	18
$C_{10}H_{22}$	75
$C_{20}H_{42}$	366,319
$C_{40}H_{82}$	6.25×10^{13} (estimated)

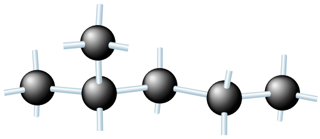
Open-Chain and Ring Compounds

The continuous sequence of carbon atoms in polyethylene (page 1048) is called a **straight chain**. This means *only* that no carbon atom bonds to more than two other carbons. It does not refer to the *shape* of the molecule. If we made a molecular model of polyethylene and coiled it into a spiral, we would still say that its carbon skeleton has a straight chain. It has no branches.

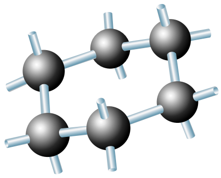
Branched chains are also very common. For example, isooctane, the standard for the octane rating of gasoline, has a *main chain* of five carbon atoms (in black) carrying three CH_3 *branches* (shown in red).



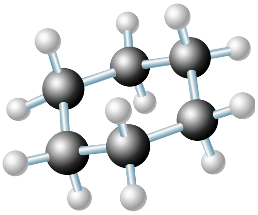
Straight chain



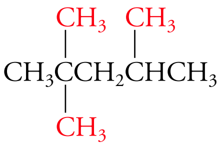
Branched chain



Carbon ring



Cyclohexane

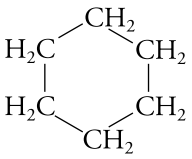


$$CH_3\overset{\overset{CH_3}{|}}{\underset{\underset{CH_3}{|}}{C}}CH_2\overset{\overset{CH_3}{|}}{C}HCH_3$$

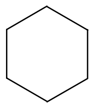
isooctane

■ Isooctane, one of the many alkanes in gasoline, is the standard for the octane ratings of various types of gasoline. Pure isooctane is assigned an octane rating of 100.

Carbon rings are also common. Cyclohexane, for example, has a ring of six carbon atoms:



cyclohexane



cyclohexane
(fully condensed)

Just about everything is "understood" in the very convenient, fully condensed structure of cyclohexane. When polygons, like the hexagon, are used to represent rings, the following conventions are used:

Using Polygons to Represent Rings

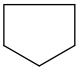
1. C occurs at each corner unless O or N (or another atom capable of forming more than one bond) is explicitly written at a corner.
2. A line connecting two corners is a covalent bond (single bond) between adjacent ring atoms.
3. Remaining bonds, as required by the carbon at a corner to have a total of four bonds, are understood to hold H atoms.
4. Double bonds are always explicitly shown.

Polygons as condensed structures

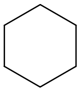
We can illustrate these rules with the following cyclic compounds:

cyclopropane

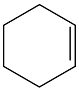
cyclobutane



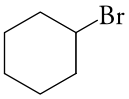
cyclopentane



cyclohexane



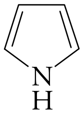
cyclohexene



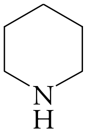
bromocyclohexane

There is no theoretical upper limit to the size of a ring.

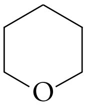
Many compounds have **heterocyclic** rings. Their molecules carry an atom other than carbon in a ring position, as in pyrrole, piperidine, and tetrahydropyran.



pyrrole



piperidine



tetrahydropyran

■ The tetrahydropyran ring occurs in molecules of sugar.

The atom other than carbon is called the *heteroatom*, and any atoms of H or other element bonded to it are not "understood" but are always shown.

Notation similar to that for rings is often used for open-chain molecules as well. For example, the structure of pentane can be represented as follows:

$H_3C-CH_2-CH_2-CH_2-CH_3$

pentane

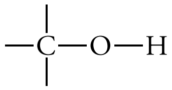
On the right, the four bonds between carbon atoms are represented by four connected line segments. At the end of each line segment (including where line segments join) there is a carbon atom plus enough hydrogen atoms to account for the four bonds that the carbon must have.

Organic Families and Their Functional Groups

The study of the huge number of organic compounds is manageable because they can be sorted into *organic families* defined by *functional groups*, a number of which were described in Chapter 9 and summarized in Table 9.2 on page 375. A more complete list is found in Table 23.1. In the pages ahead we will examine some of the reactions of functional groups.

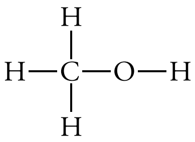
Functional groups are small structural units within molecules at which most of the compound's chemical reactions occur. For example, all *alcohols* have the *alcohol group*, which imparts certain chemical properties that are common to them all. The simplest member of the alcohol family, methanol (also called methyl alcohol), has molecules with only one carbon. Ethanol molecules have two carbons. Similarly, all members of the family of *carboxylic acids* (organic acids) have the *carboxyl group*. The carboxylic acid with two carbons per molecule is the familiar weak acid, ethanoic acid (better known as acetic acid).

■ Recall from Chapter 9 that organic acids contain the carboxyl group.



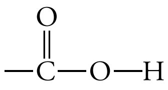
$-\overset{|}{\underset{|}{C}}-O-H$

alcohol group



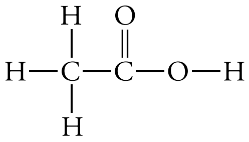
$H-\overset{\overset{H}{|}}{\underset{\underset{H}{|}}{C}}-O-H$

methanol
(methyl alcohol)



$-\overset{\overset{O}{\|}}{C}-O-H$

carboxyl group



$H-\overset{\overset{H}{|}}{\underset{\underset{H}{|}}{C}}-\overset{\overset{O}{\|}}{C}-O-H$

ethanoic acid
(acetic acid)

Functional groups

Table 23.1 Some Important Families of Organic Compounds

Family	Characteristic Structural Feature[a]	Example
Hydrocarbons	Only C and H present	
	Families of Hydrocarbons:	
	Alkanes: only single bonds	CH_3CH_3
	Alkenes: C═C	$CH_2{=}CH_2$
	Alkynes: C≡C	$HC{\equiv}CH$
	Aromatic: Benzene ring	Alcohols	ROH	CH_3CH_2OH
Ethers	ROR′	CH_3OCH_3
Aldehydes	 $R\overset{O}{\overset{\|}{C}}H$	 $CH_3\overset{O}{\overset{\|}{C}}H$
Ketones	 $R\overset{O}{\overset{\|}{C}}R'$	 $CH_3\overset{O}{\overset{\|}{C}}CH_3$
Carboxylic acids	 $R\overset{O}{\overset{\|}{C}}OH$	 $CH_3\overset{O}{\overset{\|}{C}}OH$
Esters	 $R\overset{O}{\overset{\|}{C}}OR'$	 $CH_3\overset{O}{\overset{\|}{C}}OCH_3$
Amines	RNH_2, $RNHR'$, $RNR'R''$	CH_3NH_2 CH_3NHCH_3  $CH_3\overset{CH_3}{\overset{\|}{N}}CH_3$
Amides	 $R\overset{O}{\overset{\|}{C}}—\overset{R''(H)}{\overset{\|}{N}}R'(H)$	 $CH_3\overset{O}{\overset{\|}{C}}N(CH_3)_2$

[a] R, R′, and R″ represent hydrocarbon groups—*alkyl groups*—defined in the text.

One family in Table 23.1, the *alkane* family, has no functional group, just C—C and C—H single bonds. These bonds are virtually nonpolar, because C and H are so alike in electronegativity. Therefore, alkane molecules are the least able of all organic molecules to attract ions or polar molecules. As a result, they do not react, at least at room temperature, with polar or ionic reactants such as strong acids and bases and common oxidizing agents, like dichromate or permanganate ions.

The Symbol R in Structural Formulas

In Tables 9.2 and 23.1 the functional groups are shown attached to the symbol R. Chemists use the symbol R in a structure to represent purely alkane-like hydrocarbon groups, which are unreactive toward substances that are able to react with the functional group. For example, one type of amine is represented by the formula R—NH_2, where R could be CH_3, CH_3CH_2, $CH_3CH_2CH_2$, and so forth. Because the amines are compounds with an ammonia-like group, they are weak Brønsted bases and, like ammonia, react with hydronium ions. We can, therefore, summarize in just one equation the reaction of a strong acid with *any* amine of the R—NH_2 type, regardless of how large the hydrocarbon portion of the molecule is, by the following equation:

$$R—NH_2 + H_3O^+ \longrightarrow R—NH_3^+ + H_2O$$

23.2 | Hydrocarbons

Petroleum refinery. The towers contain catalysts that break up large molecules in hot crude oil to smaller molecules suitable for vehicle engines. *(Martin Bond/ Photo Researchers)*

Hydrocarbons are compounds whose molecules consist of only C and H atoms. The *fossil fuels*—coal, petroleum, and natural gas—supply us with virtually all of these substances. One of the operations in petroleum refining is to boil crude oil (petroleum from which natural gas has been removed) and selectively condense the vapors between preselected temperature ranges. *Gasoline*, for example, is the fraction boiling roughly between 40 and 200 °C and is composed of molecules that have 5 to 12 carbon atoms. The *kerosene* and *jet fuel* fraction contains molecules with more carbon atoms and overlaps this range, going from 175 to 325 °C.

Hydrocarbons can be divided into four types: *alkanes*, *alkenes*, *alkynes*, and *aromatic hydrocarbons* (Table 23.1). All are insoluble in water. All burn, giving carbon dioxide and water if sufficient oxygen is available.

■ Recall from Section 6.5 that in insufficient oxygen, some carbon monoxide and carbon also form when hydrocarbons burn.

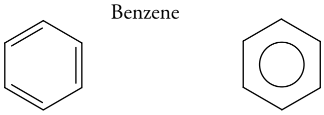
The **alkanes**, mentioned earlier, contain carbon atoms bonded to other atoms by only single bonds. In the alkanes all of the carbon atoms use sp^3 hybrid orbitals for bonding, so the orientation of atoms around each carbon is tetrahedral. Open-chain members of the alkane family have the general formula C_nH_{2n+2}.

Alkenes contain one or more carbon–carbon double bonds of the type described in Figure 10.32 on page 441. **Alkynes** contain one or more triple bonds formed as shown in Figure 10.35 on page 444. Alkenes and alkynes are said to be **unsaturated compounds** because under appropriate conditions their molecules can take up additional H atoms to give alkane molecules. We will study these reactions later. The alkanes are **saturated compounds**, compounds with only single bonds, and do not take on additional H atoms.

■ Alkanes are saturated in the sense that they have as many hydrogen atoms as the carbon atoms can hold, just as a saturated solution has as much solute as it can hold.

The **aromatic hydrocarbons**, typified by benzene, are also unsaturated because the carbon atoms of their rings, when represented by simple Lewis structures, also have double bonds.

Benzene



Lewis structure
(one of two
resonance structures)

Alternative structure that
emphasizes delocalized
bonding

The delocalized nature of the π bond system in the ring causes them to behave quite differently from alkenes and alkynes in their chemical reactions, as we discuss later.

IUPAC Nomenclature of Alkanes

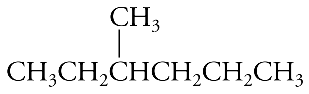
The **IUPAC rules** for naming organic compounds follow a regular pattern. The last syllable in an IUPAC name designates the family of the compound. The names of all saturated hydrocarbons, for example, end in *-ane*. For each family there is a rule for picking out and naming the *parent chain* or *parent ring* within a specific molecule. The compound is then regarded as having *substituents* attached to its parent chain or ring. Let's see how these principles work with naming alkanes.

■ In earlier discussions we gave both the official IUPAC names as well as common names for organic compounds.

Naming alkanes

IUPAC Rules for Naming the Alkanes

1. The name ending for all alkanes (and cycloalkanes) is *-ane*.
2. The *parent chain* is the longest continuous chain of carbons in the structure. For example, the branched-chain alkane

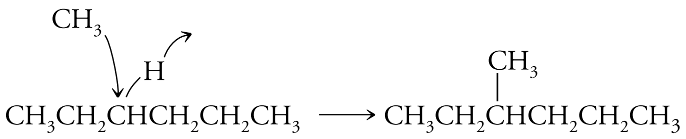


$$CH_3CH_2\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_2CH_2CH_3$$

is regarded as being "made" from the following parent

$$CH_3CH_2CH_2CH_2CH_2CH_3$$

by replacing a hydrogen atom on the third carbon from the left with CH_3.



$$CH_3CH_2\overset{\overset{\displaystyle H}{|}}{C}HCH_2CH_2CH_3 \longrightarrow CH_3CH_2\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_2CH_2CH_3$$

3. A prefix is attached to the name ending, *-ane,* to specify the number of carbon atoms *in the parent chain*. The prefixes through chain lengths of 10 carbons are as follows. The names in Table 23.2 show their use.

meth-	1 C	hex-	6 C
eth-	2 C	hept-	7 C
prop-	3 C	oct-	8 C
but-	4 C	non-	9 C
pent-	5 C	dec-	10 C

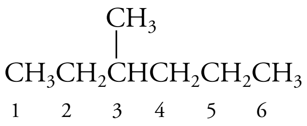
The parent chain of our example has six carbons, so the parent is named hexane—*hex* for six carbons and *ane* for being in the alkane family. Therefore, the alkane whose name we are devising is viewed as a *derivative* of this parent, *hexane*.

4. The carbon atoms of the parent chain are numbered starting from whichever end of the chain gives the location of the first branch the lower of two possible numbers. Thus, the correct direction for numbering our example is from left to

Table 23.2 Straight-Chain Alkanes

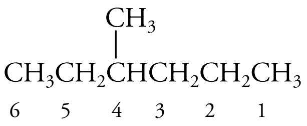
IUPAC Name	Molecular Formula	Structure	Boiling Point (°C)	Melting Point (°C)	Density (g mL^{-1}, 20 °C)
Methane	CH_4	CH_4	−161.5	−182.5	
Ethane	C_2H_6	CH_3CH_3	−88.6	−183.3	
Propane	C_3H_8	$CH_3CH_2CH_3$	−42.1	−189.7	
Butane	C_4H_{10}	$CH_3(CH_2)_2CH_3$	−0.5	−138.4	
Pentane	C_5H_{12}	$CH_3(CH_2)_3CH_3$	36.1	−129.7	0.626
Hexane	C_6H_{14}	$CH_3(CH_2)_4CH_3$	68.7	−95.3	0.659
Heptane	C_7H_{16}	$CH_3(CH_2)_5CH_3$	98.4	−90.6	0.684
Octane	C_8H_{18}	$CH_3(CH_2)_6CH_3$	125.7	−56.8	0.703
Nonane	C_9H_{20}	$CH_3(CH_2)_7CH_3$	150.8	−53.5	0.718
Decane	$C_{10}H_{22}$	$CH_3(CH_2)_8CH_3$	174.1	−29.7	0.730

right, not right to left, because this locates the branch (CH_3) at position 3, not position 4.



$$\mathrm{CH_3CH_2\overset{\overset{CH_3}{|}}{C}HCH_2CH_2CH_3}$$

(correct direction of numbering)



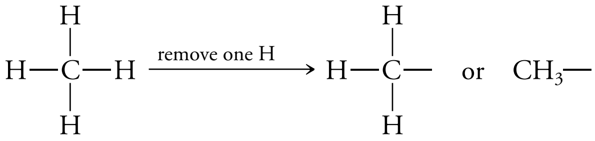
$$\mathrm{CH_3CH_2\overset{\overset{CH_3}{|}}{C}HCH_2CH_2CH_3}$$

(incorrect direction of numbering)

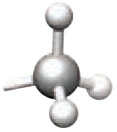
5. Each branch attached to the parent chain is named, so we must now learn the names of some of the alkane-like branches.

Alkyl Groups

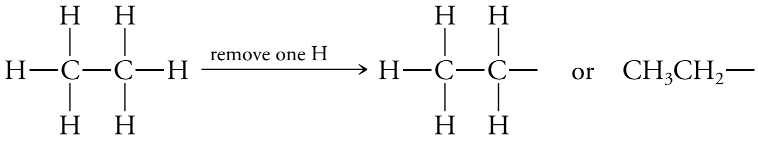
Any branch that consists only of carbon and hydrogen and has only single bonds is called an **alkyl group,** and the names of all alkyl groups end in *-yl*. Think of an alkyl group as an alkane minus one of its hydrogen atoms. For example,



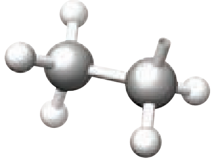
methane methyl



methyl group

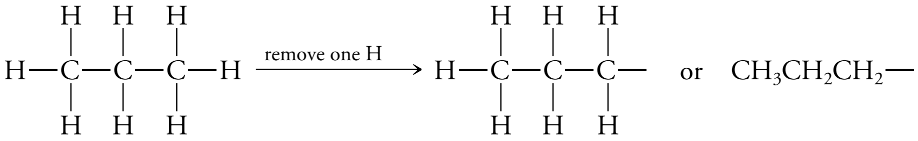


ethane ethyl

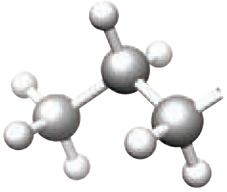


ethyl group

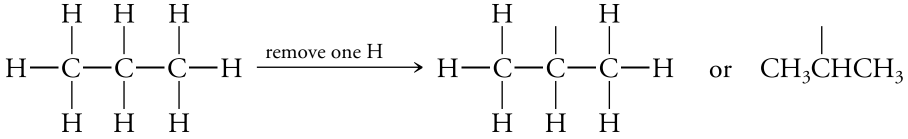
Two alkyl groups can be obtained from propane because the middle position in its chain of three is not equivalent to either of the end positions.



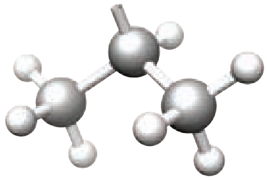
propane propyl



propyl group



propane 1-methylethyl (isopropyl)

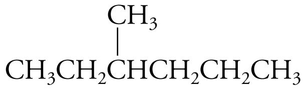


1-methylethyl group (isopropyl group)

■ Isopropyl is the common name; 1-methylethyl is the official IUPAC name.

We will not need to know the IUPAC names for any alkyl groups with four or more carbon atoms. Now let's continue with our IUPAC rules.

6. The name of each alkyl group is attached to the name of the parent as a prefix, placing its chain location number in front, separating the number from the name by a hyphen. Thus, the original example is named 3-methylhexane.

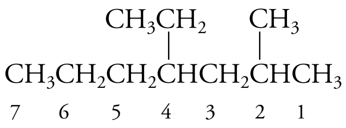


$$\mathrm{CH_3CH_2\overset{\overset{CH_3}{|}}{C}HCH_2CH_2CH_3}$$

3-methylhexane

7. When two or more groups are attached to the parent, each is named and located with a number. The names of alkyl substituents are assembled in their alphabetical

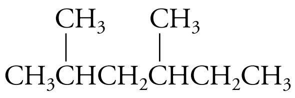
order. Always use *hyphens* to separate numbers from words. The following molecule provides an illustration:



$$CH_3CH_2CH_2\overset{CH_3CH_2}{\overset{|}{C}}HCH_2\overset{CH_3}{\overset{|}{C}}HCH_3$$

4-ethyl-2-methylheptane

8. When two or more substituents are identical, multiplier prefixes are used: di- (for 2), tri- (for 3), tetra- (for 4), and so forth. The location number of every group must occur in the final name. Always separate a number from another number in a name by a *comma*. For example,

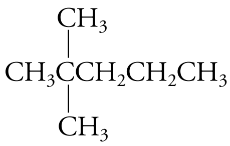


$$CH_3\overset{CH_3}{\overset{|}{C}}HCH_2\overset{CH_3}{\overset{|}{C}}HCH_2CH_3$$

Correct name: 2,4-dimethylhexane

Incorrect names: 2,4-methylhexane
3,5-dimethylhexane
2-methyl-4-methylhexane
2-4-dimethylhexane

9. When identical groups are on the *same* carbon, the number of this position is repeated in the name. For example,



$$CH_3\underset{CH_3}{\underset{|}{\overset{CH_3}{\overset{|}{C}}}}CH_2CH_2CH_3$$

Correct name: 2,2-dimethylpentane

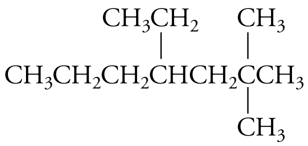
Incorrect names: 2-dimethylpentane
2,2-methylpentane
4,4-dimethylpentane

■ *Common names* are still widely used for many compounds. For example, the common name of 2-methylpropane is *isobutane*.

These are not all of the IUPAC rules for alkanes, but they will handle all of our needs.

Example 23.1
Using the IUPAC Rules to Name an Alkane

What is the IUPAC name for the following compound?



$$CH_3CH_2CH_2\overset{CH_3CH_2}{\overset{|}{C}}HCH_2\underset{CH_3}{\underset{|}{\overset{CH_3}{\overset{|}{C}}}}CH_3$$

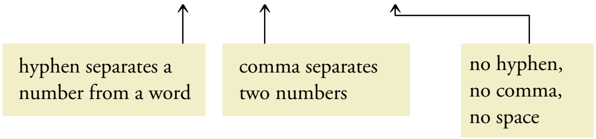
■ **Analysis:** In naming an organic compound, the first step is to identify which family it belongs to, because the rules differ slightly according to the functional group. The compound is a hydrocarbon, and by studying the structure, we can see that there are only single bonds. Therefore, the substance is an alkane.

■ **Assembling the Tools:** Our tool, of course, is the IUPAC rules for naming alkanes.

■ **Solution:** The ending to the name must be *-ane*. The longest chain is seven carbons long, so the name of the parent alkane is *heptane*. We have to number the chain from right to left in order to reach the first branch with the lower number.

At carbon 2, there are two one-carbon methyl groups. At carbon 4, there is a two-carbon ethyl group. Alphabetically, *ethyl* comes before *methyl*, so we must assemble these names as follows to make the final name. (Names of alkyl groups are alphabetized *before* any prefixes such as di- or tri- are affixed.)

4-ethyl-2,2-dimethylheptane



hyphen separates a number from a word

comma separates two numbers

no hyphen, no comma, no space

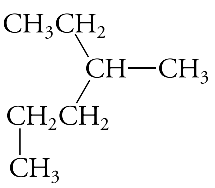
Is the Answer Reasonable? The most common mistake is to pick a shorter chain than the true "parent," a mistake we did not make. Another common mistake is to number the chain incorrectly. One overall check that some people use is to count the number of carbons implied by the name (in our example, 2 + 1 + 1 + 7 = 11) and compare it to the count obtained directly from the structure. If the counts don't match, you know you can't be right.

Practice Exercises

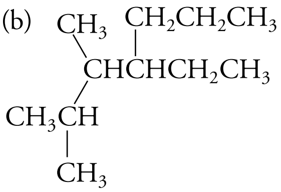
23.1 | A student incorrectly named a compound 1,1,1-trimethylethane. What should the name be? (*Hint:* Write the structure of 1,1,1-trimethylethane.)

23.2 | Write the IUPAC names of the following compounds. In searching for the parent chain, be sure to look for the longest continuous chain of carbons *even if the chain twists and goes around corners.*

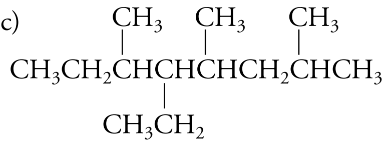
(a)



(b)



(c)



$$CH_3CH_2\overset{\displaystyle CH_3}{\overset{|}{C}}H\underset{\displaystyle CH_3CH_2}{\underset{|}{C}}H\overset{\displaystyle CH_3}{\overset{|}{C}}HCH_2\overset{\displaystyle CH_3}{\overset{|}{C}}HCH_3$$

Chemical Properties of Alkanes

Alkanes are relatively unreactive at room temperature. They do not react with concentrated acids such as H_2SO_4 or concentrated aqueous bases such as NaOH. Like all hydrocarbons, alkanes burn in air to give water and oxides of carbon (CO_2 and CO). *Hot* nitric acid, chlorine, and bromine also react with alkanes. The chlorination of methane, for example, can be made to give the following compounds:

CH_3Cl	CH_2Cl_2	$CHCl_3$	CCl_4
methyl chloride	methylene chloride	chloroform	carbon tetrachloride

■ Halogens form single bonds to carbon atoms. These are the common names for the chlorinated derivatives of methane, not the IUPAC names.

When heated at high temperatures in the absence of air, alkanes "crack," meaning that they break up into smaller molecules. The cracking of methane, for example, yields finely powdered carbon and hydrogen.

$$CH_4 \xrightarrow{\text{high temperature}} C + 2H_2$$

The controlled cracking of ethane gives ethene, commonly called ethylene.

$$\underset{\text{ethane}}{CH_3CH_3} \xrightarrow{\text{high temperature}} \underset{\text{ethene}}{CH_2{=}CH_2} + H_2$$

Ethene ("ethylene"), from the cracking of ethane, is one of the most important raw materials in the organic chemicals industry. It is used to make polyethylene plastic items as well as ethanol and ethylene glycol (an antifreeze).

■ $HOCH_2CH_2OH$
ethylene glycol

Alkenes and Alkynes

Hydrocarbons with one or more double bonds are members of the alkene family. Open-chain alkenes have the general formula, C_nH_{2n}. Hydrocarbons with triple bonds are in the alkyne family, and have the general formula, C_nH_{2n-2} (when open-chain).

Alkenes and alkynes, like all hydrocarbons, are virtually nonpolar and therefore insoluble in water, and they are flammable. The most familiar alkenes are ethene and propene (commonly called ethylene and propylene, respectively), the raw materials for polyethylene and polypropylene, respectively. Ethyne ("acetylene"), an important alkyne, is the fuel for oxyacetylene torches.

$\mathrm{CH_2{=}CH_2}$ ethene (ethylene)

$\mathrm{CH_3CH{=}CH_2}$ propene (propylene)

$\mathrm{HC{\equiv}CH}$ ethyne (acetylene)

■ The IUPAC accepts both *ethene* and *ethylene* as the name of $\mathrm{CH_2{=}CH_2}$. The common name of propene is *propylene*, and other simple alkenes have common names as well.

TOOLS

Naming alkenes and alkynes

IUPAC Nomenclature of Alkenes and Alkynes

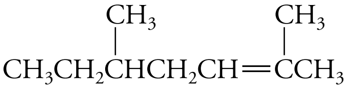
The IUPAC rules for the names of alkenes are adaptations of those for alkanes, but with two important differences. First, the parent chain *must include the double bond* even if this means that the parent chain is shorter than another. Second, the parent alkene chain must be *numbered from whichever end gives the first carbon of the double bond the lower of two possible numbers.* This (lower) number, preceded and followed by a hyphen, is inserted into name of the parent chain just before the -ene or -yne ending, unless there is no ambiguity about where the double bond occurs. The numbers for the locations of branches are not considered in numbering the chain. Otherwise, alkyl groups are named and located as before. Some examples of correctly named alkenes are as follows:

$\mathrm{CH_3CH_2CH{=}CH_2}$

but-1-ene
(not but-3-ene)

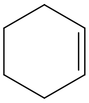
$\mathrm{CH_3CH{=}CHCH_3}$

but-2-ene



$\mathrm{CH_3CH_2\overset{\overset{CH_3}{|}}{C}HCH_2CH{=}\overset{\overset{CH_3}{|}}{C}CH_3}$

2,5-dimethylhept-2-ene
(not 3,6-dimethyl-5-heptene)



cyclohexene

Notice that only one number is used to locate the double bond, the number of the first carbon of the double bond to be reached as the chain is numbered.

Some alkenes have two double bonds and are called *dienes*. Some have three double bonds and are called *trienes*, and so forth. Each double bond has to be located by a number.

$\mathrm{CH_2{=}CHCH{=}CHCH_3}$ penta-1,3-diene

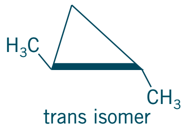
$\mathrm{CH_2{=}CHCH_2CH{=}CH_2}$ penta-1,4-diene

$\mathrm{CH_2{=}CHCH{=}CHCH{=}CH_2}$ hexa-1,3,5-triene

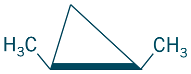
Geometric Isomerism

As explained in Section 10.6, rotation of one part of a molecule relative to another around a carbon–carbon double bond cannot occur without bond breaking (see page 440). As a result, the orientations of the atoms bonded to the carbons of the double bond are locked in place. This allows many alkenes to exhibit **geometric isomerism**. Thus, *cis*-but-2-ene and *trans*-but-2-ene (commonly called *cis*-2-butene and *trans*-2-butene, respectively) are **geometric isomers** of each other (see below). They not only have the same molecular formula, $\mathrm{C_4H_8}$, but also the same skeletons and the same organization of atoms and bonds—namely, $\mathrm{CH_3CH{=}CHCH_3}$. The two 2-butenes differ in the *directions* taken by the two $\mathrm{CH_3}$ groups attached at the double bond.

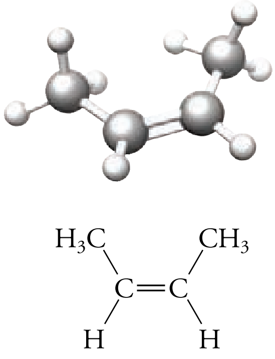
■ Because ring structures also lock out free rotation, geometric isomers of ring compounds are also possible. These two isomers of 1,2-dimethylcyclopropane are examples. In the representations below, the ring is viewed tilting back into the page, with the front edge of the ring shown as a heavy line.



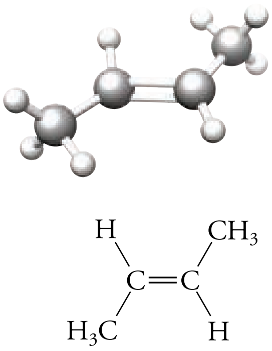
trans isomer
BP 28 °C



cis isomer
BP 37 °C



cis-but-2-ene
BP 3.72 °C



trans-but-2-ene
BP 0.88 °C

Cis means "on the same side;" trans means "on opposite sides." This difference in orientation gives the two geometric isomers of 2-butene measurable differences in physical properties, as their boiling points show. Because each has a double bond, however, the *chemical* properties of *cis*- and *trans*-2-butene are very similar.

Reactions of Alkenes

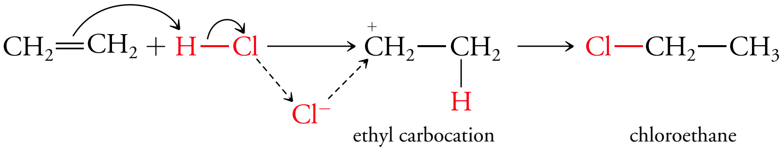
A double bond has more electron density than a single bond, so electron-seeking species such as protons are naturally attracted to the electron density at the π bond of the double bond. As a result, alkenes can react readily with protons provided by strong proton donors to give **addition reactions** in which two parts of a reactant become separately attached to the two carbons of a double bond. Ethene, for example, readily reacts with hydrogen chloride as follows:

$$CH_2{=}CH_2 + H{-}Cl(g) \longrightarrow Cl{-}CH_2{-}CH_3$$

TOOLS

Reactions of alkenes and alkynes

We say that the hydrogen chloride molecule *adds across the double bond*, the hydrogen of HCl going to the carbon at one end and the chlorine going to the other end. The pair of electrons of the π bond move out and take H^+ from HCl, which releases Cl^-. A positive (+) charge is left at one end of the original carbon–carbon double bond as a bond to H forms at the other end.



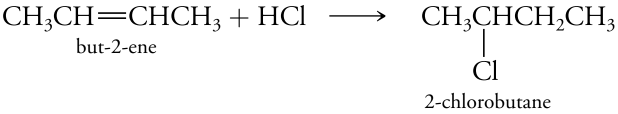
$CH_2{=}CH_2 + H{-}Cl \longrightarrow \overset{+}{C}H_2{-}CH_2{-}H \longrightarrow Cl{-}CH_2{-}CH_3$
Cl^-
ethyl carbocation
chloroethane

■ Recall that curved arrows indicate how electron pairs rearrange; they usually are not used to signify the movement of atoms.

The result of H^+ transfer is a very unstable cation called a *carbocation*, an ion with a positive charge on carbon. This charged site then quickly attracts the Cl^- ion to give the product, chloroethane.

■ A carbocation, having a carbon with only six valence electrons, not an octet, generally has only a fleeting existence.

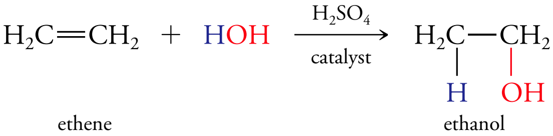
Another example is 2-butene; like ethene, it too adds HCl.



$$\underset{\text{but-2-ene}}{CH_3CH{=}CHCH_3} + HCl \longrightarrow \underset{\text{2-chlorobutane}}{CH_3\underset{Cl}{\underset{|}{C}}HCH_2CH_3}$$

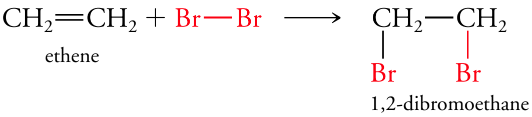
Alkene double bonds also add hydrogen bromide, hydrogen iodide, and sulfuric acid ("hydrogen sulfate"). Alkynes undergo similar addition reactions.

A water molecule adds to a double bond if an acid catalyst, like sulfuric acid, is present. The resulting product is an alcohol. For example, adding H_2O to the double bond of ethene gives ethanol as the product.



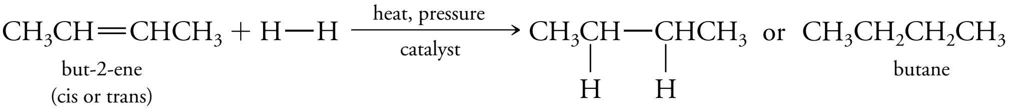
$$\underset{\text{ethene}}{H_2C{=}CH_2} + HOH \xrightarrow[\text{catalyst}]{H_2SO_4} \underset{\text{ethanol}}{\underset{H}{\underset{|}{H_2C}}{-}\underset{OH}{\underset{|}{CH_2}}}$$

Other inorganic compounds that add to an alkene double bond are chlorine, bromine, and hydrogen. Chlorine and bromine react rapidly at room temperature. Ethene, for example, reacts with bromine to give 1,2-dibromoethane.



$$\underset{\text{ethene}}{CH_2{=}CH_2} + Br{-}Br \longrightarrow \underset{\text{1,2-dibromoethane}}{\underset{Br}{\underset{|}{CH_2}}{-}\underset{Br}{\underset{|}{CH_2}}}$$

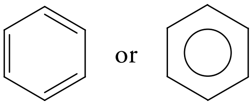
The product of the addition of hydrogen to an alkene is an alkane and the reaction is called *hydrogenation*. It requires a catalyst—powdered platinum, for example—and sometimes a higher temperature and pressure than available under an ordinary room atmosphere. The hydrogenation of 2-butene (cis or trans) gives butane.



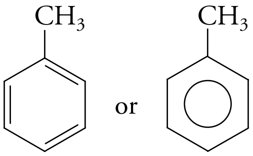
$$\underset{\substack{\text{but-2-ene}\\ \text{(cis or trans)}}}{CH_3CH{=}CHCH_3} + H{-}H \xrightarrow[\text{catalyst}]{\text{heat, pressure}} CH_3\underset{H}{\underset{|}{C}}H{-}\underset{H}{\underset{|}{C}}HCH_3 \text{ or } \underset{\text{butane}}{CH_3CH_2CH_2CH_3}$$

Aromatic Hydrocarbons

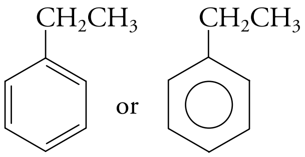
The most common **aromatic compounds** contain the *benzene ring*, a ring of six carbon atoms, each bonded to one H or one other atom or group. The benzene ring is represented as a hexagon either with alternating single and double bonds or with a circle. For example,



benzene



toluene
(methylbenzene)



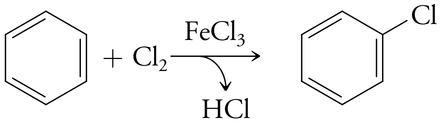
ethylbenzene

■ Hydrocarbons and their oxygen or nitrogen derivatives that are not aromatic are called *aliphatic compounds*.

The circle better suggests the delocalized bonds of the benzene ring, which are described in Section 10.8.

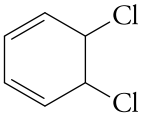
In the molecular orbital view of benzene, discussed in Section 10.8, the delocalization of the ring's π electrons strongly stabilizes the ring. This explains why benzene does not easily give addition reactions; they would interfere with the delocalization of electron density. Instead, the benzene ring most commonly undergoes **substitution reactions**, those in which one of the ring H atoms is replaced by another atom or group. For example, benzene reacts with chlorine in the presence of iron(III) chloride to give chlorobenzene, instead of a 1,2-dichloro compound. To dramatize this point, we must use a resonance structure for benzene (see page 452).

■ In this reaction, $FeCl_3$ is a catalyst. The HCl is a product, indicated by the second, curved arrow.



chlorobenzene

Not



(This would form if chlorine *added* to the double bond.)

You can infer that *substitution,* but not addition, leaves intact the delocalized and very stable π electron network of the benzene ring.

Provided that a suitable catalyst is present, benzene reacts by substitution with chlorine, bromine, and nitric acid as well as with sulfuric acid. (Recall that Cl_2 and Br_2 readily *add* to alkene double bonds.)

$$C_6H_6 + Br_2 \xrightarrow{\text{FeBr}_3\text{ catalyst}} \underset{\text{bromobenzene}}{C_6H_5\text{—}Br} + HBr$$

$$C_6H_6 + HNO_3 \xrightarrow{\text{H}_2\text{SO}_4\text{ catalyst}} \underset{\text{nitrobenzene}}{C_6H_5\text{—}NO_2} + H_2O$$

$$C_6H_6 + H_2SO_4 \longrightarrow \underset{\text{benzenesulfonic acid}}{C_6H_5\text{—}SO_3H} + H_2O$$

23.3
Organic Compounds Containing Oxygen

Most of the organic compounds we encounter are not hydrocarbons, although they all contain fragments that are considered to be derived from hydrocarbons. In this section we study compounds that possess the oxygen-containing functional groups in Table 23.1.

Alcohols and Ethers

Alcohols were discussed in Chapter 9. In general, they include any compound with an OH group bonded to a carbon that is also attached to three other groups by *single bonds*. Using the symbol R to represent any alkyl group, alcohols have ROH as their general structure.

The four structurally simplest alcohols are the following (their common names are in parentheses below their IUPAC names):

CH_3OH	CH_3CH_2OH	$CH_3CH_2CH_2OH$	 $CH_3\underset{\displaystyle OH}{\underset{\vert}{C}}HCH_3$
methanol (methyl alcohol) BP 65 °C	ethanol (ethyl alcohol) BP 78.5 °C	propan-1-ol (propyl alcohol) BP 97 °C	propan-2-ol (isopropyl alcohol) BP 82 °C

Ethanol is the alcohol in beverages and is also added to gasoline to make "gasohol" and makes up 85% of the fuel E-85 (the rest is gasoline).

Molecules of **ethers** contain two alkyl groups joined to one oxygen, the two R groups being alike or different. We give only the common names for the following examples:

CH_3OCH_3	$CH_3CH_2OCH_2CH_3$	$CH_3OCH_2CH_3$	R—O—R′
dimethyl ether BP −23 °C	diethyl ether BP 34.5 °C	methyl ethyl ether BP 11 °C	ethers (general structure)

Diethyl ether is the "ether" that was once widely used as an anesthetic during surgery.

The contrasting boiling points of alcohols and ethers illustrate the influence of hydrogen bonding. Hydrogen bonds cannot exist between molecules of ethers and the simple ethers have very low boiling points, being substantially lower than those of alcohols of comparable molecular sizes. For example, 1-butanol, $CH_3CH_2CH_2CH_2OH$ (BP 117 °C) boils 83 degrees higher than its structural isomer, diethyl ether (BP 34.5 °C).

Naming Alcohols

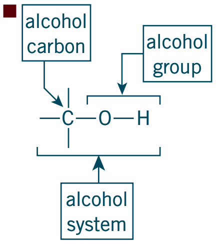
The name ending for an alcohol is *-ol*. It replaces the *-e* ending of the name of the hydrocarbon that corresponds to the parent. The parent chain of an alcohol must be the longest *that includes the carbon holding the OH group*. The chain is numbered to give the site of the OH group the lower number regardless of where alkyl substituents occur.

Naming alcohols

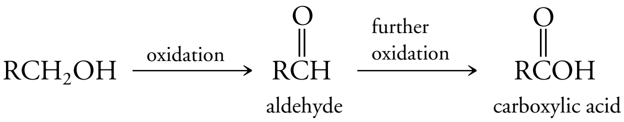
Major Reactions of Alcohols and Ethers

Ethers are almost as chemically inert as alkanes. They burn (as do alkanes), and they are split apart when boiled in concentrated acids.

The alcohols, in contrast, have a rich chemistry. When the carbon atom of the alcohol system, the *alcohol carbon atom,* is also bonded to at least one H, this H can be removed by an oxidizing agent. The H atom of the OH group will also leave, and the oxygen will form a double bond with the carbon. The two H atoms become part of a water molecule, and we may think of the oxidizing agent as providing the O atom for H_2O. At this point, the number of H atoms that remain on the original alcohol carbon then determines the *family* of the product.



The oxidation of an alcohol of the RCH_2OH type, with two H atoms on the alcohol carbon, produces first an *aldehyde*, which is further oxidized to a *carboxylic acid*. (We will say more about aldehydes and carboxylic acids later in this section.)



$$RCH_2OH \xrightarrow{\text{oxidation}} \underset{\text{aldehyde}}{R\overset{\displaystyle O}{\overset{\Vert}{C}}H} \xrightarrow[\text{oxidation}]{\text{further}} \underset{\text{carboxylic acid}}{R\overset{\displaystyle O}{\overset{\Vert}{C}}OH}$$

Oxidation of alcohols

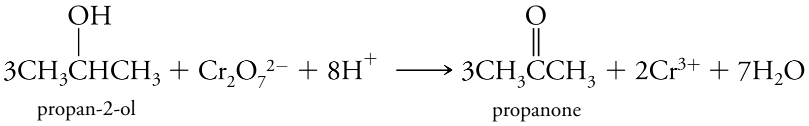
The net ionic equation for the formation of the aldehyde when dichromate ion is used is

$$3RCH_2OH + Cr_2O_7^{2-} + 8H^+ \longrightarrow 3RCH{=}O + 2Cr^{3+} + 7H_2O$$

■ The aldehyde group, CH═O, is one of the most easily oxidized, and the carboxyl group, CO_2H, is one of the most oxidation resistant of the functional groups.

Aldehydes are much more easily oxidized than alcohols, so unless the aldehyde is removed from the solution as it forms, it will consume oxidizing agent that has not yet reacted and be changed to the corresponding carboxylic acid.

The oxidation of an alcohol of the R_2CHOH type produces a *ketone*. For example, the oxidation of 2-propanol gives propanone.



$$3CH_3\underset{\text{propan-2-ol}}{\overset{OH}{CH}}CH_3 + Cr_2O_7^{2-} + 8H^+ \longrightarrow 3CH_3\overset{O}{\overset{\|}{C}}CH_3 + 2Cr^{3+} + 7H_2O$$

propan-2-ol

propanone
(acetone, a ketone)

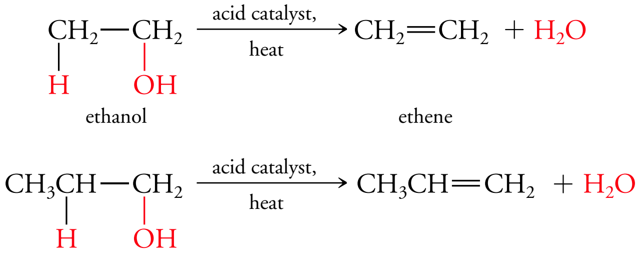
Ketones strongly resist oxidation, so a ketone does not have to be removed from the oxidizing agent as it forms.

Alcohols of the type R_3COH have no removable H atom on the alcohol carbon, so they cannot be oxidized in a similar manner.

Other Reactions of Alcohols

In the presence of a strong acid, like concentrated sulfuric acid, an alcohol molecule can undergo the loss of a water molecule, leaving behind a carbon–carbon double bond. This reaction, called **dehydration,** is one example of an **elimination reaction.** For example,

Dehydration of alcohols



$$\underset{H}{CH_2}{-}\underset{OH}{CH_2} \xrightarrow[\text{heat}]{\text{acid catalyst,}} CH_2{=}CH_2 + H_2O$$

ethanol

ethene

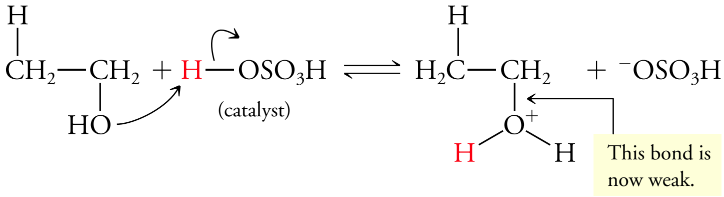
$$CH_3\underset{H}{CH}{-}\underset{OH}{CH_2} \xrightarrow[\text{heat}]{\text{acid catalyst,}} CH_3CH{=}CH_2 + H_2O$$

propan-1-ol

propene

What makes the elimination of water possible is the proton-accepting ability of the O atom of the OH group. Alcohols resemble water in that they react like Brønsted bases toward concentrated strong acids to give an equilibrium mixture involving a protonated form. Ethanol, for example, dissolves in and reacts with concentrated sulfuric acid by the following reaction (H_2SO_4 is written as H—OSO_3H):[1]

■ Remember: the curved arrows in these diagrams show how *electrons* rearrange during the reaction. They don't indicate the movements of the atoms.



$$\overset{H}{CH_2}{-}\underset{HO}{CH_2} + \underset{\text{(catalyst)}}{H{-}OSO_3H} \rightleftharpoons H_2\overset{H}{C}{-}\underset{\underset{H\quad H}{O^+}}{CH_2} + {}^-OSO_3H$$

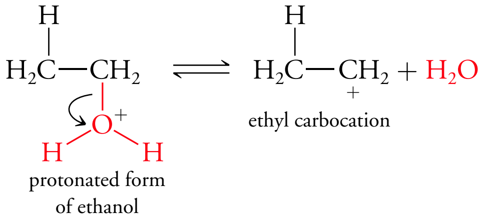
This bond is now weak.

The organic cation is nothing more than the ethyl derivative of the hydronium ion, $CH_3CH_2OH_2^+$, and *all three bonds to oxygen in this cation are weak*, just like all three bonds to oxygen in H_3O^+.

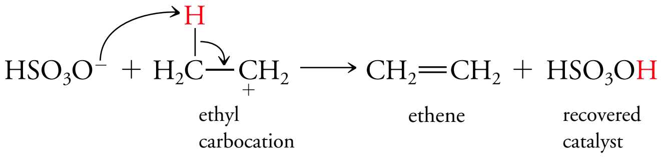
A water molecule now leaves, taking with it the electron pair that held it to the CH_2 group. The remaining organic species is a carbocation.

---

[1] The first curved arrow illustrates how an atom attached to one molecule, like the O of the HO group, uses an unshared pair of electrons to pick up an atom of another molecule, like the H of the catalyst. The second curved arrow shows that *both* electrons of the bond from H to O in sulfuric acid remain in the hydrogen sulfate ion that forms. Thus H transfers as H^+.



Carbocations are unstable. The ethyl carbocation, $CH_3CH_2^+$, loses a proton to become more stable, donating it to a proton acceptor such as HSO_3O^- to reform the catalyst HSO_3H. The electron pair that was used in the bonding to the departing proton stays behind to become the second bond of the new double bond in the product. The next equation illustrates this step. All carbon atoms now have outer octets.



The last few steps in the dehydration of ethanol—the separation of H_2O, loss of the proton, formation of the double bond, and recovery of the catalyst—probably occur simultaneously. Notice two things about the catalyst, H_2SO_4. First, it works to convert a species with strong bonds, the alcohol, to one with weak bonds strategically located, the protonated alcohol. Second, the H_2SO_4 is recovered, as it must be if it is to be considered a catalyst.

Under acidic conditions, the OH group of an alcohol can be *replaced* by a halogen atom using a concentrated strong binary acid. For example,

Substitution reactions of alcohols

$$\underset{\text{ethanol}}{CH_3CH_2OH} + HI(\text{conc.}) \xrightarrow{\text{heat}} \underset{\substack{\text{iodoethane}\\\text{(ethyl iodide)}}}{CH_3CH_2I} + H_2O$$

$$\underset{\text{propan-1-ol}}{CH_3CH_2CH_2OH} + HBr(\text{conc.}) \xrightarrow{\text{heat}} \underset{\substack{\text{1-bromopropane}\\\text{(propyl bromide)}}}{CH_3CH_2CH_2Br} + H_2O$$

These reactions, like that between chlorine and benzene in Section 23.2, are **substitution reactions.** The first step in each is the transfer of H^+ to the OH of the alcohol to give the protonated form of the OH group.

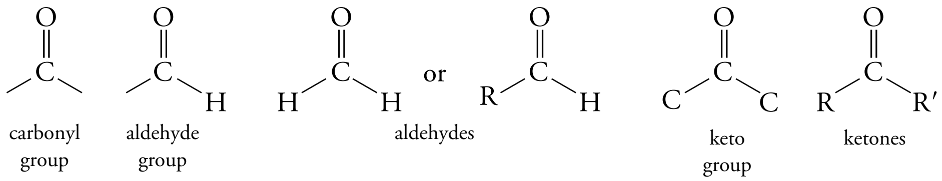
$$R{-}OH + H^+ \longrightarrow R{-}OH_2^+$$

The acid catalyst works to weaken the R—O bond in R—OH by adding H^+ to form $R{-}OH_2^+$. Given the high concentration of halide ion, X^-, it is this species that successfully reacts with $R{-}OH_2^+$ to displace OH_2 (H_2O) and yield $R{-}X$.

Aldehydes and Ketones

In Chapter 9 we described the **carbonyl group,** $>C{=}O$, and noted its presence in aldehydes and ketones, and we've seen how these compounds are formed in the oxidation of alcohols.

What differentiates aldehydes from ketones are the atoms attached to the carbon of the C=O group. When the carbon atom of the carbonyl group binds an H atom plus a hydrocarbon group (or a second H), the compound is an *aldehyde*. When C=O is bonded to two hydrocarbon groups at C, the compound is a *ketone*.



The *aldehyde group* is often condensed to CHO, the double bond of the carbonyl group being "understood." The *ketone group* (or *keto* group) is sometimes similarly condensed to CO.

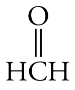
The polar carbonyl group can participate in hydrogen bonding, which helps to make compounds containing it much more soluble in water than hydrocarbons of roughly the same molecular size.

The carbonyl group occurs widely. As an aldehyde group, it's in the molecules of most sugars, like glucose. Another common sugar, fructose, has the keto group.

Naming Aldehydes and Ketones

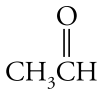
Naming aldehydes and ketones

The IUPAC name ending for an aldehyde is *-al.* The parent chain is the longest chain *that includes the aldehyde group*. Thus, the three-carbon aldehyde is named *propanal*, because "propane" is the name of the three-carbon alkane and the *-e* in propane is replaced by *-al.* Because, by definition, the aldehyde group must be at the end of a chain, the numbering of the chain always starts by assigning the carbon of the aldehyde group position 1. This rule makes it unnecessary to include the number locating the aldehyde group in the name, as illustrated by the name 2-methylpropanal.



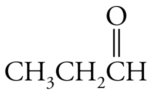
$H\overset{\overset{O}{\|}}{C}H$

methanal
BP −21 °C



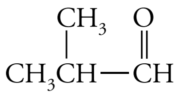
$CH_3\overset{\overset{O}{\|}}{C}H$

ethanal
BP 21 °C



$CH_3CH_2\overset{\overset{O}{\|}}{C}H$

propanal
BP 49 °C



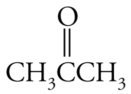
$CH_3\overset{\overset{CH_3}{|}}{C}H-\overset{\overset{O}{\|}}{C}H$

2-methylpropanal
(not 2-methyl-1-propanal)
BP 64 °C

Aldehydes cannot form hydrogen bonds between their own molecules, so they boil at lower temperatures than alcohols of comparable molecular size.

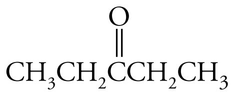
The name ending for the IUPAC names of ketones is *-one*. The parent chain must include the carbonyl group and be numbered from whichever end reaches the carbonyl carbon first. The number of the ketone group's location must be part of the name whenever there would otherwise be uncertainty.

■ We need not write "propan-2-one," because if the carbonyl carbon is anywhere else in a three-carbon chain, the compound could not be a ketone; it would be the *aldehyde*, propanal.



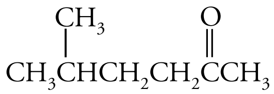
$CH_3\overset{\overset{O}{\|}}{C}CH_3$

propanone
(acetone)
BP 56.5 °C



$CH_3CH_2\overset{\overset{O}{\|}}{C}CH_2CH_3$

pentan-3-one
BP 101.5 °C



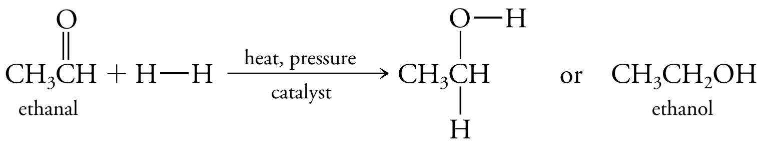
$CH_3\overset{\overset{CH_3}{|}}{C}HCH_2CH_2\overset{\overset{O}{\|}}{C}CH_3$

5-methylhexan-2-one
(not 2-methylhexan-5-one)
BP 145 °C

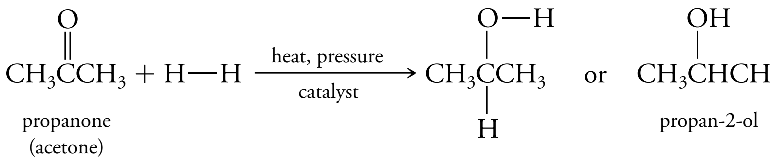
Reactions of Aldehydes and Ketones

Hydrogen is capable of adding across the double bond of the carbonyl group in both aldehydes and ketones. The reaction is just like the addition of hydrogen across the double bond of an alkene and takes place under roughly the same conditions—namely, with a metal catalyst, heat, and pressure. The reaction is called either *hydrogenation* or *reduction.* For example,

Reduction of aldehydes and ketones



$$\underset{\text{ethanal}}{CH_3\overset{\overset{O}{\|}}{C}H} + H-H \xrightarrow[\text{catalyst}]{\text{heat, pressure}} CH_3\underset{\underset{H}{|}}{\overset{\overset{O-H}{|}}{C}}H \quad \text{or} \quad \underset{\text{ethanol}}{CH_3CH_2OH}$$



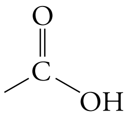
$$\underset{\text{(acetone)}}{\underset{\text{propanone}}{CH_3\overset{\overset{O}{\|}}{C}CH_3}} + H-H \xrightarrow[\text{catalyst}]{\text{heat, pressure}} CH_3\underset{\underset{H}{|}}{\overset{\overset{O-H}{|}}{C}}CH_3 \quad \text{or} \quad \underset{\text{propan-2-ol}}{CH_3\overset{\overset{OH}{|}}{C}HCH_3}$$

The H atoms take up positions at opposite ends of the carbonyl group's double bond, which then becomes a single bond holding an OH group.

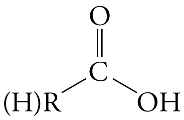
Aldehydes and ketones are in separate families because of their remarkably different behavior toward oxidizing agents. As we noted on page 1062, aldehydes are easily oxidized, but ketones strongly resist oxidation. Even in storage in a bottle, aldehydes are slowly oxidized by the oxygen of the air trapped in the bottle.

Carboxylic Acids and Esters

A **carboxylic acid** carries an OH on the carbon of the carbonyl group.



carboxyl group



carboxylic acids

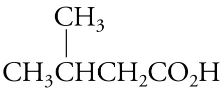
In condensed formulas the **carboxyl group** is often written as CO_2H (or sometimes COOH).

The name ending of the IUPAC names of carboxylic acids is *-oic acid.* The parent chain must be the longest that includes the carboxyl carbon, which is numbered position 1. The name of the hydrocarbon with the same number of carbons as the parent is then changed by replacing the terminal *-e* with *-oic acid.* For example,

Naming organic acids

HCO_2H
methanoic acid
(formic acid)
BP 101 °C

CH_3CO_2H
ethanoic acid
(acetic acid)
BP 118 °C



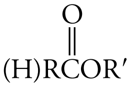
$$CH_3\underset{}{\overset{\overset{\displaystyle CH_3}{|}}{C}}HCH_2CO_2H$$

3-methylbutanoic acid
BP 176 °C

■ Because carboxylic acids have both a lone oxygen and an OH group, their molecules strongly hydrogen bond to each other. Their high boiling points, relative to alcohols of comparable molecular size, reflect this.

Carboxylic acids are used to synthesize two important kinds of derivatives, *esters* and *amides* (which are discussed in the next section). In **esters,** the OH of the carboxyl group is replaced by OR. (The H in parentheses means the group attached to the C of the carboxyl group can either be R or H.)

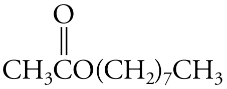
■ A *derivative* of a carboxylic acid is a compound that can be made from the acid, or can be changed to the acid by hydrolysis.



$$(H)R\overset{\overset{\displaystyle O}{\|}}{C}OR'$$

esters

or $(H)RCO_2R'$, for example,



$$CH_3\overset{\overset{\displaystyle O}{\|}}{C}O(CH_2)_7CH_3$$

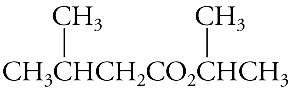
octyl ethanoate
(fragrance of oranges)

The IUPAC name of an ester begins with the name of the alkyl group attached to the O atom. This is followed by a separate word, which is taken from the name of the parent carboxylic acid by changing *-ic acid* to *-ate*. For example,

Naming esters

HCO_2CH_3
methyl methanoate
BP 31.5 °C

$CH_3CO_2CH_2CH_3$
ethylpropanoate
BP 99 °C



$$CH_3\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_2CO_2\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_3$$

isopropyl 3-methylbutanoate
BP 142 °C

Reactions of Carboxylic Acids and Esters

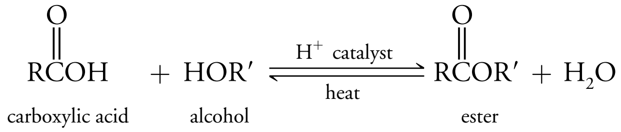
The carboxyl group is weakly acidic, causing compounds that contain it to be weak acids in water. In fact, we've used both formic acid and acetic acid in previous discussions of weak acids. All carboxylic acids, both water soluble and water insoluble, neutralize Brønsted bases such as the hydroxide, bicarbonate, and carbonate ions. The general equation for the reaction with OH^- is

$$RCO_2H + OH^- \xrightarrow{H_2O} RCO_2^- + H_2O$$

The carboxyl group is present in all of the building blocks of proteins, the amino acids, which are discussed further on page 1083.

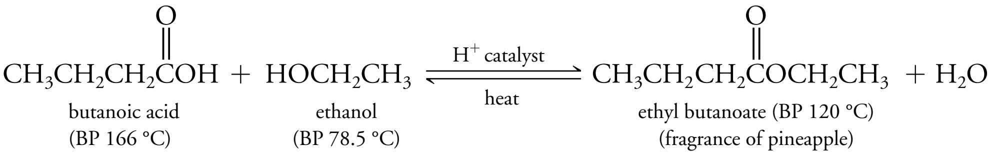
Reactions of organic acids

One way to prepare an ester is to heat a solution of the parent carboxylic acid and the alcohol in the presence of an acid catalyst. (We'll not go into the details of how this happens.) The following kind of equilibrium forms, but a substantial stoichiometric excess of the alcohol (usually the less expensive reactant) is commonly used to drive the position of the equilibrium toward the ester.



$$\underset{\text{carboxylic acid}}{R\overset{O}{\overset{\|}{C}}OH} + \underset{\text{alcohol}}{HOR'} \xrightleftharpoons[\text{heat}]{H^+\text{ catalyst}} \underset{\text{ester}}{R\overset{O}{\overset{\|}{C}}OR'} + H_2O$$

For example,

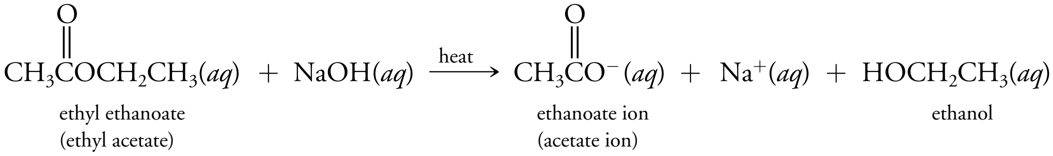


$$\underset{\substack{\text{butanoic acid}\\ \text{(BP 166 °C)}}}{CH_3CH_2CH_2\overset{O}{\overset{\|}{C}}OH} + \underset{\substack{\text{ethanol}\\ \text{(BP 78.5 °C)}}}{HOCH_2CH_3} \xrightleftharpoons[\text{heat}]{H^+\text{ catalyst}} \underset{\substack{\text{ethyl butanoate (BP 120 °C)}\\ \text{(fragrance of pineapple)}}}{CH_3CH_2CH_2\overset{O}{\overset{\|}{C}}OCH_2CH_3} + H_2O$$

An ester is hydrolyzed to its parent acid and alcohol when the ester is heated together with a stoichiometric excess of water (plus an acid catalyst). The identical equilibrium as shown above forms, but in ester hydrolysis water is in excess, so the equilibrium shifts to the left to favor the carboxylic acid and alcohol, another illustration of Le Châtelier's principle.

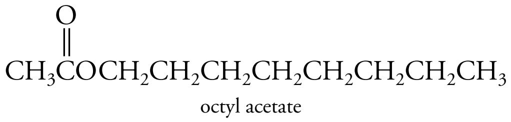
Saponification of esters

Esters are also split apart by the action of aqueous base, only now the carboxylic acid emerges not as the free acid but as its anion. The reaction is called ester **saponification**. We can illustrate it by the action of aqueous sodium hydroxide on ethyl ethanoate, a simple ester:



$$\underset{\substack{\text{ethyl ethanoate}\\ \text{(ethyl acetate)}}}{CH_3\overset{O}{\overset{\|}{C}}OCH_2CH_3(aq)} + NaOH(aq) \xrightarrow{\text{heat}} \underset{\substack{\text{ethanoate ion}\\ \text{(acetate ion)}}}{CH_3\overset{O}{\overset{\|}{C}}O^-(aq)} + Na^+(aq) + \underset{\text{ethanol}}{HOCH_2CH_3(aq)}$$

Ester groups abound among the molecules of the fats and oils in our diets. The hydrolysis of their ester groups occurs when we digest them, with an enzyme as the catalyst, not a strong acid. Because this digestion occurs in a region of the intestinal tract where the fluids are slightly basic, the anions of carboxylic acids form. Esters also tend to have pleasant aromas and are responsible for the fragrance of many fruits. For example, octyl acetate,



$$\underset{\text{octyl acetate}}{CH_3\overset{O}{\overset{\|}{C}}OCH_2CH_2CH_2CH_2CH_2CH_2CH_2CH_3}$$

gives oranges their characteristic odor. See the table in the margin.

Ester	**Aroma**
$HCO_2CH_2CH_3$	Rum
$HCO_2CH_2CH(CH_3)_2$	Raspberries
$CH_3CO_2(CH_2)_4CH_3$	Bananas
$CH_3CO_2(CH_2)_2CH(CH_3)_2$	Pears
$CH_3CO_2(CH_2)_7CH_3$	Oranges
$CH_3(CH_2)_2CO_2CH_2CH_3$	Pineapples
$CH_3(CH_2)_2CO_2(CH_2)_4CH_3$	Apricots

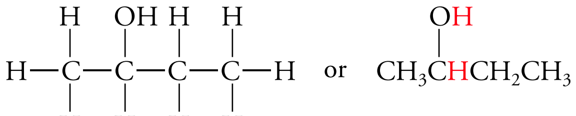
Example 23.2
Alcohol Oxidation Products

What is the structure of the organic product made by the oxidation of butan-2-ol with dichromate ion? If no oxidation can occur, so state.

Analysis: We first have to determine the structure of butan-2-ol. The oxidation product then depends on the number of hydrogens attached to the alcohol carbon atom.

Assembling the Tools: First, we have to use the nomenclature rules to draw the structure of butan-2-ol. If there are no H atoms on the alcohol carbon, oxidation by dichromate ion cannot occur. If there is one H atom on the alcohol carbon, the tool we use predicts that the product will be a ketone. If there are two H atoms on the alcohol carbon, the product will be an aldehyde.

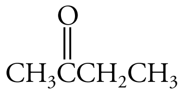
Solution: The nomenclature rules tell us that the OH group of the alcohol is on carbon number 2 of a four-carbon chain of singly bonded carbon atoms. In drawing the structure we have to remember that each carbon atom must have four bonds.



$$CH_3\overset{OH}{\overset{|}{C}}HCH_2CH_3$$

butan-2-ol

The alcohol carbon has one H atom, so the product will be a ketone. The oxidation results in the detachment of both the H atom on the alcohol carbon (carbon 2) and the one joined to the O atom of the OH group, leaving a double bond to O. We simply erase the two H atoms shown in red and insert a double bond from C to O. (The product is called *butanone.*)



$$CH_3\overset{O}{\overset{\|}{C}}CH_2CH_3$$

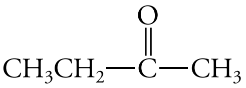
butanone (a ketone)

Is the Answer Reasonable? The starting material had two alkyl groups, CH_3 and CH_2CH_3. It doesn't matter what these alkyl groups are, however, because the reaction takes the same course in all cases. All alcohols of the R_2CHOH type can be oxidized to ketones in this way.

The "skeleton" of heavy atoms, C and O, does not change in this kind of oxidation, and butanone has the same skeleton as butan-2-ol. The oxidation also produces a double bond from C to O, as we showed.

Practice Exercises

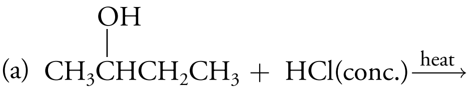
23.3 | Oxidation of an alcohol gave the following product. What was the formula of the original alcohol? (*Hint:* How many hydrogens are removed from the alcohol carbon by oxidation?)



$$CH_3CH_2—\overset{O}{\overset{\|}{C}}—CH_3$$

23.4 | What are the structures of the products (if any) that form from the oxidation of the following alcohols by dichromate ion? (a) ethanol, (b) pentan-3-ol, (c) 2-methylpropan-2-ol

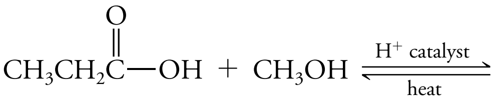
23.5 | Write the structural formula(s) for the principal organic product(s) in the following reactions:



(a) $CH_3\overset{OH}{\overset{|}{C}}HCH_2CH_3 + HCl(conc.) \xrightarrow{heat}$

(b) $CH_3CH_2CH_2OH \xrightarrow[Conc.]{H_2SO_4}$

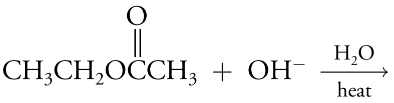
23.6 | Complete the following equation and write the structural formula for the principal organic product. What is the name of the product?



$$CH_3CH_2\overset{O}{\overset{\|}{C}}—OH + CH_3OH \underset{heat}{\overset{H^+ \text{ catalyst}}{\rightleftharpoons}}$$

23.7 | Write structural formulas for the following: (a) 3-methylbutanal, (b) ethyl propionate, and (c) butanone.

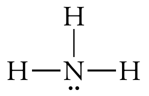
23.8 | Write the structural formula(s) for the principal organic product(s) in the following reaction:



$$CH_3CH_2O\overset{O}{\overset{\|}{C}}CH_3 + OH^- \xrightarrow[heat]{H_2O}$$

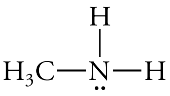
23.4 | Organic Derivatives of Ammonia

As described in Chapter 9, **amines** can be viewed as organic derivatives of ammonia in which one, two, or three hydrocarbon groups have replaced hydrogens. Examples, together with their common (not IUPAC) names, are



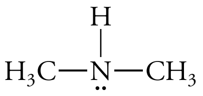
$$\mathrm{H{-}\overset{\displaystyle H}{\overset{|}{\underset{\cdot\cdot}{N}}}{-}H}$$

ammonia
BP −33.4 °C



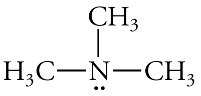
$$\mathrm{H_3C{-}\overset{\displaystyle H}{\overset{|}{\underset{\cdot\cdot}{N}}}{-}H}$$

methylamine
BP −8 °C



$$\mathrm{H_3C{-}\overset{\displaystyle H}{\overset{|}{\underset{\cdot\cdot}{N}}}{-}CH_3}$$

dimethylamine
BP 8 °C



$$\mathrm{H_3C{-}\overset{\displaystyle CH_3}{\overset{|}{\underset{\cdot\cdot}{N}}}{-}CH_3}$$

trimethylamine
BP 3 °C

■ The following are in the order of decreasing strengths of intermolecular attractions.

CH_3CH_2OH, BP 78.5 °C

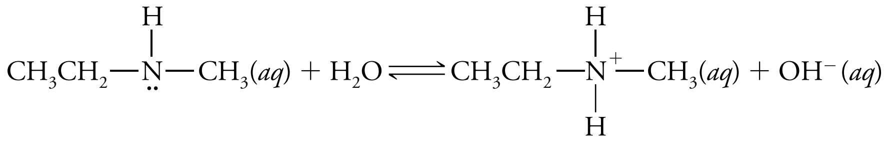
$CH_3CH_2NH_2$, BP 17 °C

$CH_3CH_2CH_3$, BP −42 °C

The N—H bond is not as polar as the O—H bond, so hydrogen bonding is not as strong and amines boil at lower temperatures than alcohols of comparable molecular size. Amines of low molecular mass are soluble in water. Hydrogen bonding between molecules of water and the amine facilitates the solution process.

Basicity and Reactions of Amines

On page 376, amines were described as weak Brønsted bases. Behaving like ammonia, amines that are able to dissolve in water establish an equilibrium in which a low concentration of hydroxide ion exists. For example,

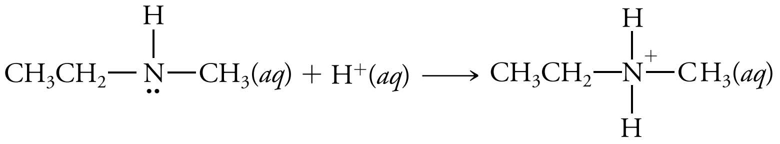


$$\mathrm{CH_3CH_2{-}\overset{\displaystyle H}{\overset{|}{\underset{\cdot\cdot}{N}}}{-}CH_3}(aq) + \mathrm{H_2O} \rightleftharpoons \mathrm{CH_3CH_2{-}\overset{\displaystyle H}{\overset{|}{\underset{\underset{\displaystyle H}{|}}{N^+}}}{-}CH_3}(aq) + \mathrm{OH^-}(aq)$$

ethylmethylamine ethylmethylammonium ion

As a result, aqueous solutions of amines test basic to litmus and have pH values above 7.

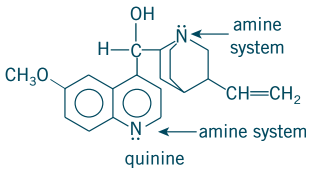
When an amine is mixed with a strong acid such as hydrochloric acid, the amine and acid react almost quantitatively. The amine accepts a proton and changes almost entirely into its protonated form. For example,



$$\mathrm{CH_3CH_2{-}\overset{\displaystyle H}{\overset{|}{\underset{\cdot\cdot}{N}}}{-}CH_3}(aq) + \mathrm{H^+}(aq) \longrightarrow \mathrm{CH_3CH_2{-}\overset{\displaystyle H}{\overset{|}{\underset{\underset{\displaystyle H}{|}}{N^+}}}{-}CH_3}(aq)$$

ethylmethylamine ethylmethylammonium ion (a protonated amine)

■



quinine
(an antimalarial drug)

Even water-insoluble amines undergo this reaction and the resulting salt is much more soluble in water that the original electrically neutral amine.

Many important medicinal chemicals, like quinine (which is used to treat malaria), are amines, but they are usually supplied to patients in protonated forms so that the drug can be administered as an aqueous solution, not as a solid. This strategy is particularly important for medicinals that must be given by intravenous drip.

Protonated Amines as Weak Brønsted Acids

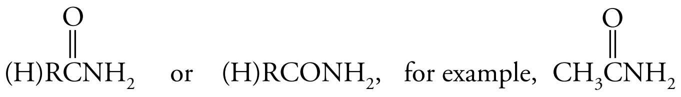
A protonated amine is a substituted ammonium ion. Like the ammonium ion itself, protonated amines are weak Brønsted acids. They can neutralize strong base. For example,

$$\underset{\text{methylammonium ion}}{\mathrm{CH_3NH_3{}^+}(aq)} + \mathrm{OH^-}(aq) \longrightarrow \underset{\text{methylamine}}{\mathrm{CH_3NH_2}(aq)} + \mathrm{H_2O}$$

This reverses the protonation of an amine and releases the uncharged amine molecule.

Amides: Derivatives of Carboxylic Acids

Carboxylic acids can also be converted to *amides*, a functional group found in proteins. In **amides,** the OH of the carboxyl group is replaced by nitrogen, which may also be bonded to any combination of H atoms or hydrocarbon groups.



$$\text{(H)R}\overset{\overset{\text{O}}{\|}}{\text{C}}\text{NH}_2 \quad \text{or} \quad \text{(H)RCONH}_2, \quad \text{for example,} \quad \text{CH}_3\overset{\overset{\text{O}}{\|}}{\text{C}}\text{NH}_2$$

simple amides

ethanamide (acetamide)

The *simple amides* are those in which the nitrogen bears no hydrocarbon groups, only two H atoms. In the place of either or both of these H atoms, however, there can be a hydrocarbon group, and the resulting substance is still an amide.

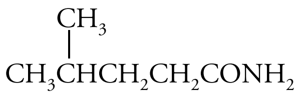
The IUPAC names of the simple amides are devised by first writing the name of the parent carboxylic acid. Then its ending, *-oic acid*, is replaced by *-amide*. For example,

$CH_3CH_2CONH_2$

propanamide

$CH_3CH_2CH_2CH_2CONH_2$

pentanamide

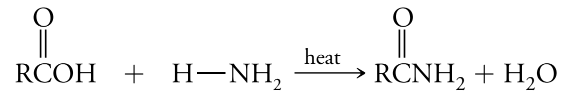


$$\text{CH}_3\underset{}{\overset{\overset{\text{CH}_3}{|}}{\text{C}}}\text{HCH}_2\text{CH}_2\text{CONH}_2$$

4-methylpentanamide

One of the ways to prepare simple amides parallels that of the synthesis of esters—that is, by heating a mixture of the carboxylic acid and an excess of ammonia.

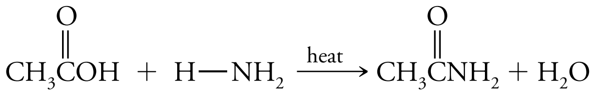
In general:



$$\text{R}\overset{\overset{\text{O}}{\|}}{\text{C}}\text{OH} + \text{H—NH}_2 \xrightarrow{\text{heat}} \text{R}\overset{\overset{\text{O}}{\|}}{\text{C}}\text{NH}_2 + \text{H}_2\text{O}$$

carboxylic acid ammonia simple amide

An example:



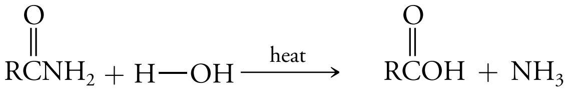
$$\text{CH}_3\overset{\overset{\text{O}}{\|}}{\text{C}}\text{OH} + \text{H—NH}_2 \xrightarrow{\text{heat}} \text{CH}_3\overset{\overset{\text{O}}{\|}}{\text{C}}\text{NH}_2 + \text{H}_2\text{O}$$

ethanoic acid ammonia ethanamide

Formation of amides

Amides, like esters, can be hydrolyzed. When simple amides are heated with water, they change back to their parent carboxylic acids and ammonia. Both strong acids and strong bases promote the reaction. As the following equations show, the reaction is the reverse of the formation of an amide.

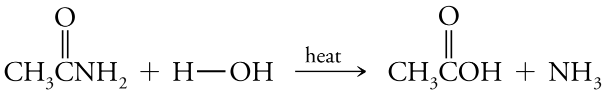
In general:



$$\text{R}\overset{\overset{\text{O}}{\|}}{\text{C}}\text{NH}_2 + \text{H—OH} \xrightarrow{\text{heat}} \text{R}\overset{\overset{\text{O}}{\|}}{\text{C}}\text{OH} + \text{NH}_3$$

simple amide carboxylic acid

An example:

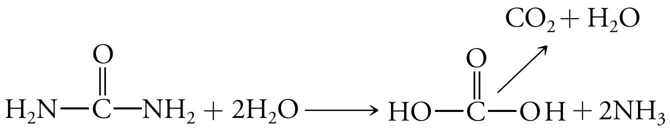


$$\text{CH}_3\overset{\overset{\text{O}}{\|}}{\text{C}}\text{NH}_2 + \text{H—OH} \xrightarrow{\text{heat}} \text{CH}_3\overset{\overset{\text{O}}{\|}}{\text{C}}\text{OH} + \text{NH}_3$$

ethanamide ethanoic acid

Hydrolysis of an amide

Urea, excreted in urine, is the amide of carbonic acid, H_2CO_3, and when it is hydrolyzed the products are ammonia and carbon dioxide (formed in the decomposition of H_2CO_3).



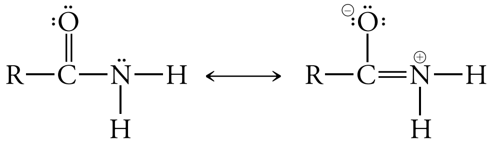
$$\text{H}_2\text{N—}\overset{\overset{\text{O}}{\|}}{\text{C}}\text{—NH}_2 + 2\text{H}_2\text{O} \longrightarrow \text{HO—}\overset{\overset{\text{O}}{\|}}{\text{C}}\text{—OH} + 2\text{NH}_3 \qquad \nearrow \text{CO}_2 + \text{H}_2\text{O}$$

urea carbonic acid

This reaction explains why a baby's wet diaper gradually develops the odor of ammonia. Urea is used commercially as a fertilizer because its hydrolysis in the soil releases ammonia, a good source of nitrogen for plants.

Nonbasicity of Amides

Despite the presence of the NH_2 group in simple amides, the amides are not Brønsted bases like amines or ammonia. This can be understood by examining the following two resonance structures:

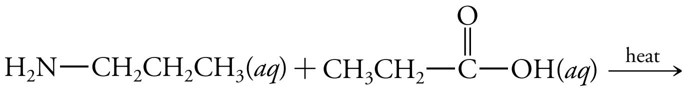


Structure 1 Structure 2

Effectively, the lone pair on the nitrogen in Structure 1 becomes partially delocalized onto the oxygen, as shown in Structure 2. This makes the lone pair on the amide nitrogen less available for donation to an H^+ than the corresponding lone pair on the nitrogen of an amine. As a result, the amide nitrogen has little tendency to acquire a proton, so amides are neutral compounds in an acid–base sense.

Practice Exercises

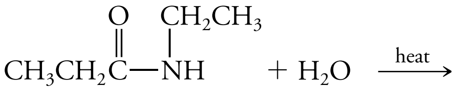
23.9 | Complete the following equation by drawing structural formulas for the products.



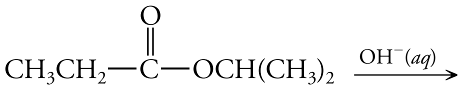
$$H_2N—CH_2CH_2CH_3(aq) + CH_3CH_2—\overset{\overset{\displaystyle O}{\|}}{C}—OH(aq) \xrightarrow{\text{heat}}$$

(*Hint:* Identify the functional groups and their properties.)

23.10 | Write the structural formula(s) for the principal organic product(s) in the following reactions:



$$\text{(a)}\ CH_3CH_2\overset{\overset{\displaystyle O}{\|}}{C}—\overset{\overset{\displaystyle CH_2CH_3}{|}}{N}H + H_2O \xrightarrow{\text{heat}}$$



$$\text{(b)}\ CH_3CH_2—\overset{\overset{\displaystyle O}{\|}}{C}—OCH(CH_3)_2 \xrightarrow{OH^-(aq)}$$

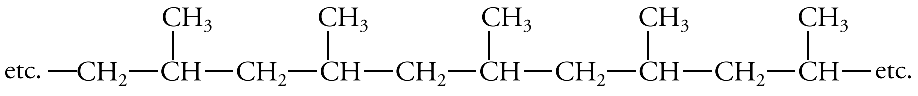
$$\text{(c)}\ CH_3CH_2CH_2CH_2OH \xrightarrow[\text{Conc.}]{H_2SO_4}$$

23.5 | Organic Polymers

Nearly all of the compounds that we've studied so far are composed of relatively small molecules. Many of the substances we encounter in the world around us, however, are composed of **macromolecules**—molecules made up of hundreds or even thousands of atoms. In nature, substances with macromolecules are almost everywhere you look. They include the fibers that give strength to trees and things made of wood, and they include proteins and the DNA found in all living creatures. Macromolecules of biological origin are discussed in Section 23.6; in this section we look at synthetic macromolecules, such as those found in plastics and synthetic fibers.

Order within Polymer Molecules

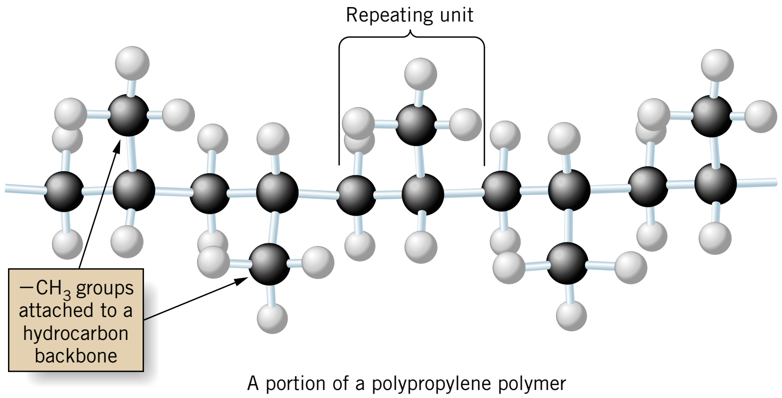
A **polymer** is a macromolecular substance whose molecules all have a small characteristic structural feature that repeats itself over and over. An example is *polypropylene*, a polymer with many uses, including dishwasher-safe food containers, indoor-outdoor carpeting, and artificial turf. The molecules of polypropylene have the following general structure:



$$\text{etc.}-\mathrm{CH_2}-\overset{\mathrm{CH_3}\atop|}{\mathrm{CH}}-\mathrm{CH_2}-\overset{\mathrm{CH_3}\atop|}{\mathrm{CH}}-\mathrm{CH_2}-\overset{\mathrm{CH_3}\atop|}{\mathrm{CH}}-\mathrm{CH_2}-\overset{\mathrm{CH_3}\atop|}{\mathrm{CH}}-\mathrm{CH_2}-\overset{\mathrm{CH_3}\atop|}{\mathrm{CH}}-\text{etc.}$$

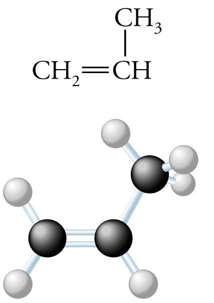
polypropylene

Notice that the polymer consists of a long carbon chain (the polymer's **backbone**) with CH_3 groups attached at periodic intervals.[2]



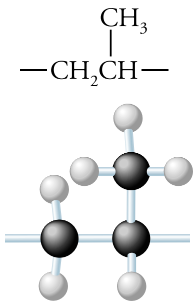
A portion of a polypropylene polymer

If you study this structure, you can see that one structural unit occurs repeatedly (actually thousands of times). In fact, the structure of a polymer is usually represented by the use of only its repeating unit, enclosed in parentheses, with a subscript *n* standing for several thousand units.



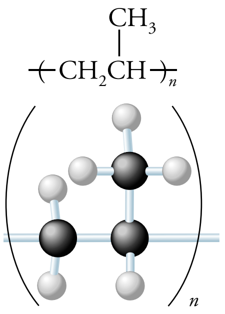
$$\mathrm{CH_2}=\overset{\mathrm{CH_3}\atop|}{\mathrm{CH}}$$

propylene



$$-\mathrm{CH_2}\overset{\mathrm{CH_3}\atop|}{\mathrm{CH}}-$$

repeating unit in polypropylene



$$\left(\mathrm{CH_2}\overset{\mathrm{CH_3}\atop|}{\mathrm{CH}}\right)_n$$

polypropylene

The value of *n* is not a constant for every molecule in a given polymer sample. A polymer, therefore, does not consist of molecules identical in *size*, just identical in *kind*; they have the same repeating unit. Notice that despite the *-ene* ending (which is used in naming alkenes), "polypropylene" has no double bonds. The polymer is named after its starting material, propylene (IUPAC name, propene).

The repeating unit of a polymer is contributed by a chemical raw material called a **monomer**. Thus propylene is the monomer for polypropylene. The reaction that makes a polymer out of a monomer is called **polymerization**, and the verb is "to polymerize." Most (but not all) useful polymers are formed from monomers that are considered to be organic compounds.

---

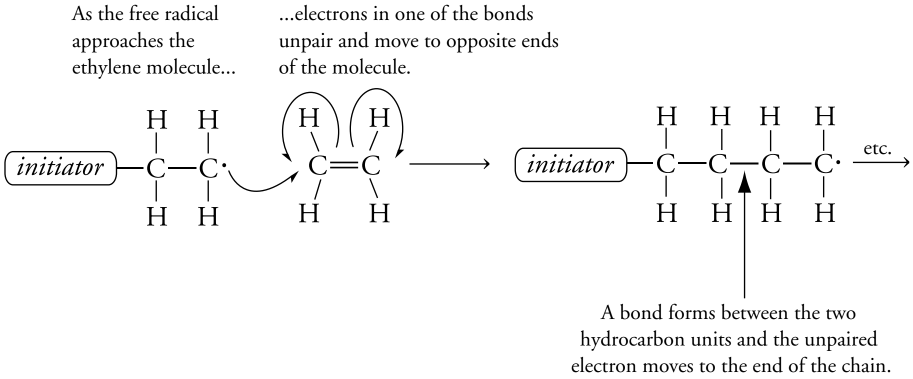
[2] The drawing of the molecule shows one way the CH_3 groups can be oriented relative to the backbone and each other. Other orientations are also possible, and they affect the physical properties of the polymer.

Chain-Growth Polymers

There are basically two ways that monomers become joined to form polymers—addition and condensation. In the simple addition of one monomer unit to another, the process continues over and over until a very long chain of monomer units is produced. Polymers formed by this process are called **chain-growth polymers** or **addition polymers.** Polypropylene, discussed previously, is an example of a chain-growth polymer, as is *polyethylene*, formed from ethylene ($CH_2{=}CH_2$) monomer units. Under the right conditions and with the aid of a substance called an *initiator*, a pair of electrons in the carbon–carbon double bond of ethylene becomes unpaired. The initiator binds to one carbon, leaving an unpaired electron on the other carbon. The result is a very reactive substance called a *free radical*, which can attack the double bond of another ethylene. In the attack, one of the electron pairs of the double bond becomes unpaired. One of the electrons becomes shared with the unpaired electron of the free radical, forming a bond that joins the two hydrocarbon units together. The other unpaired electron moves to the end of the chain, as illustrated in the following reaction sequence:

TOOLS

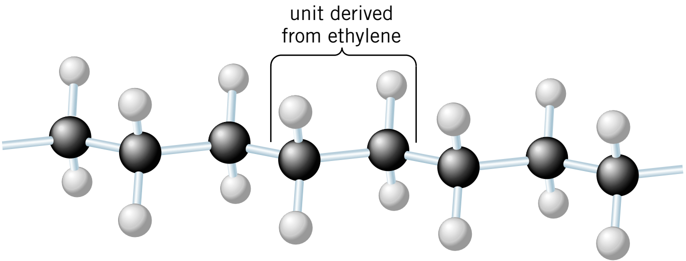
Addition polymerization



As the free radical approaches the ethylene molecule...
...electrons in one of the bonds unpair and move to opposite ends of the molecule.
initiator
H
C
initiator
etc.
A bond forms between the two hydrocarbon units and the unpaired electron moves to the end of the chain.

This process is repeated over and over as a long hydrocarbon chain grows. Eventually the chain becomes terminated and the result is a polyethylene molecule. The molecule is so large that the initiator, which is still present at one end of the chain, is an insignificant part of the whole, so in writing the structure of the polymer, the initiator is generally ignored.

■ Actually, after ethylene has polymerized, the repeating unit in polyethylene is simply CH_2.

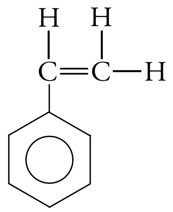


unit derived from ethylene

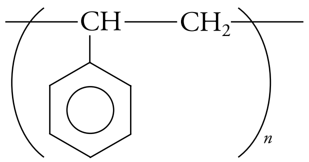
A portion of a polyethylene molecule. Although formed from a monomer with the formula C_2H_4, the actual repeating unit is CH_2.

The process by which the polymer forms has a significant influence on its ultimate structure. For example, the least expensive method for making polyethylene leads to **branching**, which means that polymer chains grow off the main backbone of the molecule as it grows longer. Other, more expensive procedures produce molecules without branching, which has a significant impact on the properties of the polymer.

In addition to polyethylene and polypropylene, another very common chain-growth polymer, called **polystyrene**, is formed by polymerizing styrene,



styrene ($C_6H_5—CH{=}CH_2$)



polystyrene

Notice that styrene is similar to propylene, but with a benzene ring in place of the methyl group ($—CH_3$). Therefore, in the polymer we find $C_6H_5—$ attached to every other atom in the hydrocarbon backbone. Polystyrene has almost as many applications as polyethylene. It's used to make clear plastic drinking glasses, molded car parts, and housings of things like computers and kitchen appliances. Sometimes a gas, like carbon dioxide, is blown through molten polystyrene as it is molded into articles. As the hot liquid congeals, tiny pockets of gas are trapped, and the product is a foamed plastic, like the familiar Styrofoam® cups or insulation materials (Figure 23.3).

Hundreds of substances similar to ethylene, propylene, and styrene, as well as their halogen derivatives, have been tested as monomers, and Table 23.3 lists some examples.

Figure 23.3 | **Styrofoam.** Made of polystyrene, Styrofoam is widely used as an insulation in construction. *(Dennis MacDonald/PhotoEdit)*

■ A "halogen derivative" is a compound in which one or more halogen atoms substitute for hydrogens in a parent molecule. Thus, CH_3Cl is halogen derivative of CH_4.

Table 23.3 Some Addition Polymers Formed from Compounds Related to Ethylene, $CH_2{=}CH_2$

Polymer	Monomer	Uses
Polyethylene	$CH_2{=}CH_2$	Grocery bags, bottles, children's toys, bullet-proof vests
Polypropylene	 $CH_2{=}CH(CH_3)$	Dishwasher-safe plastic kitchenware, indoor-outdoor carpeting, rope
Polystyrene		Plastic cups, toys, housings for kitchen appliances, Styrofoam insulation
Polyvinyl chloride (PVC)	$CH_2{=}CHCl$	Insulation, credit cards, vinyl siding for houses, bottles, plastic pipe
Polytetrafluoroethylene (Teflon)	$F_2C{=}CF_2$	Nonstick surfaces on cookware, valves
Polyvinyl acetate (PVA)		Latex paint, coatings, glue, molded items
Polymethyl methacrylate (Lucite)		Shatter-resistant windows, coatings, acrylic paints, molded items

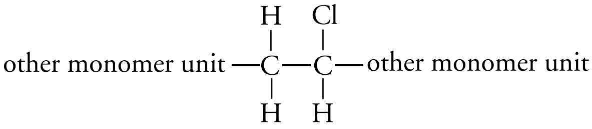
Example 23.3
Writing the Formula for a Chain-Growth Polymer

Use the information in Table 23.3 to write the structure of the polymer polyvinyl chloride showing three repeat units. Write the general formula for this polymer.

Analysis: The polymer we're dealing with is a chain-growth polymer, so we can anticipate that the entire $CH_2{=}CHCl$ molecule will repeat over and over. The polymer will be formed by opening the double bond, as we saw for ethylene.

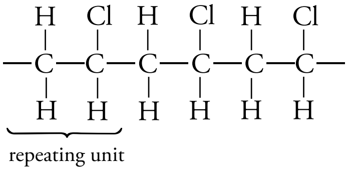
Assembling the Tools: The tool we use to solve the problem is the method by which monomer units add to each other in the formation of the polymer.

Solution: When the double bond opens, bonds to two other monomer units will form.



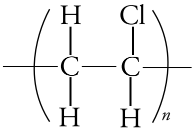
$$\text{other monomer unit}-\overset{H}{\underset{H}{C}}-\overset{Cl}{\underset{H}{C}}-\text{other monomer unit}$$

We need to attach three repeating units to have the answer to the problem.



$$-\underbrace{\overset{H}{\underset{H}{C}}-\overset{Cl}{\underset{H}{C}}}_{\text{repeating unit}}-\overset{H}{\underset{H}{C}}-\overset{Cl}{\underset{H}{C}}-\overset{H}{\underset{H}{C}}-\overset{Cl}{\underset{H}{C}}-$$

The general formula for the polymer should indicate the repeating unit occurring *n* times.



$$-\!\left(\overset{H}{\underset{H}{C}}-\overset{Cl}{\underset{H}{C}}\right)_{n}\!-$$

Is the Answer Reasonable? There's not much to check here, other than to be sure that the repeating unit has the same molecular formula as the monomer, which it does.

Practice Exercises

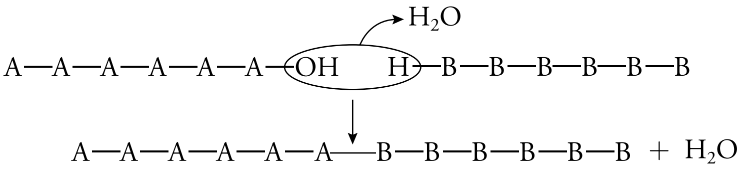
23.11 | Suppose but-2-ene were polymerized. Make a sketch showing three repeating units of the monomer in the polymer. (*Hint:* What is the structure of but-2-ene?)

23.12 | Write a formula showing three repeating units of the monomer in the polymer Teflon. (See Table 23.3.)

Step-Growth Polymers

The second way that monomer units can combine to form a polymer is by a process called **condensation**, in which a small molecule is eliminated when the two monomer units become joined. In a simplified way, we can diagram this as follows.

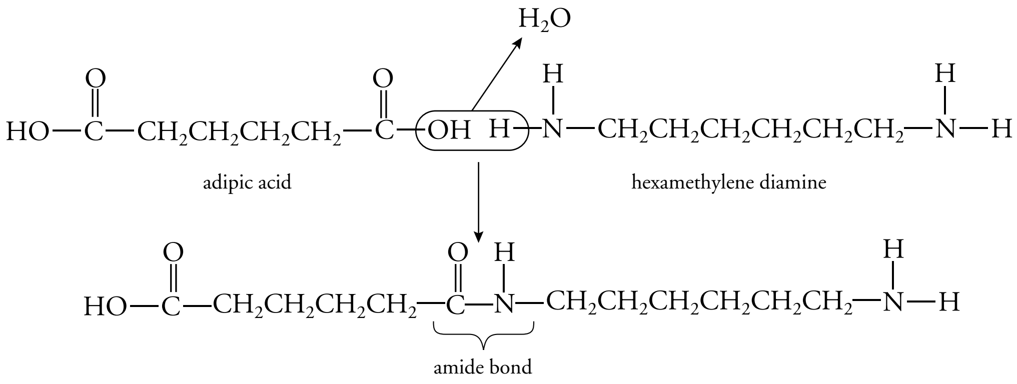
Condensation polymerization



H_2O
A—A—A—A—A—A—OH H—B—B—B—B—B—B
A—A—A—A—A—A—B—B—B—B—B—B + H_2O

In this example, an OH group from one molecule combines with an H from another, forming a water molecule. At the same time, the two molecules A and B become joined by a covalent bond. If this can be made to happen at both ends of A and B, long chains are formed and a **condensation polymer** (also called a **step-growth polymer**) is the result.

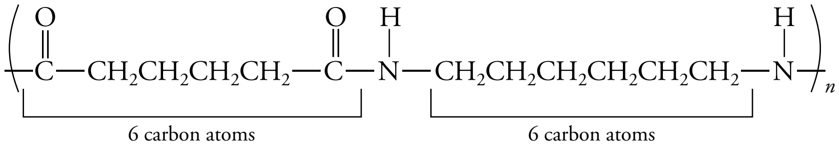
The two most familiar condensation polymers are nylon and polyesters. Nylon is formed by combining two different compounds, so it's considered a **copolymer**. The first nylon to be manufactured is called **nylon 6,6** because it forms by combining two compounds each with six carbon atoms.



Notice that adipic acid contains two carboxyl groups (it's called a dicarboxylic acid). The other compound is a diamine because it has two amine groups. By the elimination of water, the two molecules become joined by an *amide bond,* which we discussed in Section 23.4. This same linkage is found in proteins, including silk and the proteins found in our bodies.

■ As you will see later, the amide bond is found in polypeptides, the major component of proteins.

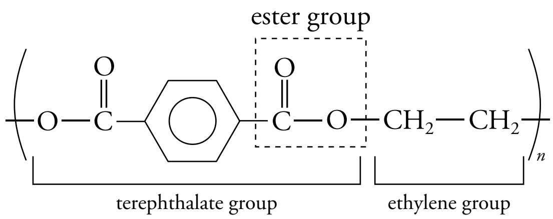
The reaction product with the amide bond still has a carboxyl group on one end and an amine group on the other, so further condensation can occur, ultimately leading to the formation of nylon 6,6.



Nylon 6,6

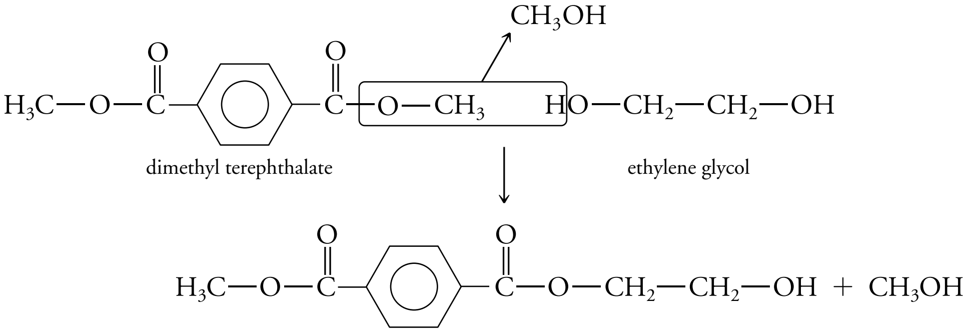
Nylon was invented in 1940 and became popular as a substitute for silk in women's stockings. It forms strong elastic fibers and is used to make fishing line as well as fibers found in all sorts of clothing and many other products.

Another type of condensation polymer uses the formation of an ester bond to join the monomers. An example of this is polyester, which is shown below.



poly(ethylene terephthalate), also known as PET

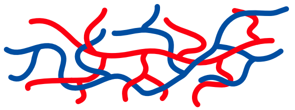
This copolymer is made by condensation of ethylene glycol, an alcohol, and dimethyl terephthalate, an ester. The first step is as follows:



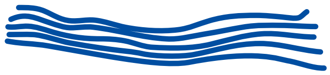
Notice that this time the small molecule that's displaced is CH_3OH, methyl alcohol, not H_2O. Continued polymerization ultimately leads to the PET polymer shown above. You may have heard of this polymer because it also goes by the name *Dacron*.

A variety of monomers can be used to form different polyesters with a range of properties. Their uses include fibers for fabrics, shatterproof plastic bottles for water and soft drinks, Mylar for making recording tapes and balloons that don't easily deflate, and shatterproof windows and eyeglasses.

Physical Properties and Polymer Crystallinity



(*a*) Two branched polymer chains become twisted with little order.



(*b*) Polymer chains are able to align, producing a tightly packed structure with a large degree of crystallinity.

Figure 23.4 | **Amorphous and crystalline polyethylene.** (*a*) When branching occurs in LDPE, the polymer strands are unable to become aligned and an amorphous product results. (*b*) Linear HDPE has a high degree of crystallinity, which makes for excellent strong fibers.

Beyond chemical stability, physical properties are the features of polymers most sought after. Desirable properties of Teflon, for example, are its chemical inertness and its slipperiness toward just about anything. Nylon isn't eaten by moths—a chemical property, in fact—but its superior strength and its ability to be made into fibers and fabrics of great beauty are what make nylon valuable. Dacron (a polyester) resists mildewing and its fibers are not weakened by mildew like those of cotton. Dacron also has greater strength with lower mass than cotton, and Dacron fibers do not stretch as much, which are properties that account for Dacron's use for making sails.

In many ways, the physical properties of a polymer are related to how the individual polymer strands are able to pack in the solid. For example, previously we noted that the least expensive way of making polyethylene yields a product that has branching. The branches prevent the molecules from lining up in an orderly fashion, so the molecules twist and intertwine to give an essentially amorphous solid (which means it lacks the kind of order found in crystalline solids). See Figure 23.4*a*. This amorphous product is called *low density polyethylene* (*LDPE*); the polymer molecules have a relatively low molecular mass and the solid has little structural strength. LDPE is the kind of polyethylene used to make the plastic bags grocery stores use to pack your purchases.

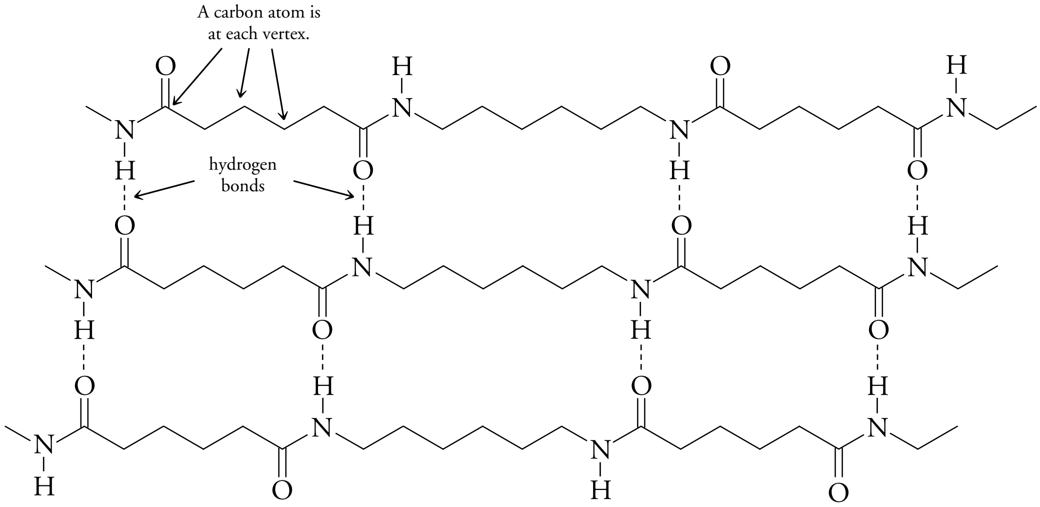
Following different methods, polyethylene can be made to form without branching and with molecular masses ranging from 200,000 to 500,000 u. This polymer is called *linear* polyethylene or *high density polyethylene, HDPE*. In HDPE, the polymer strands are able to line up alongside each other to produce a large degree of order (and therefore, crystallinity), as illustrated in Figure 23.4*b*. This enables the molecules to form fibers easily, and because the molecules are large and packed so well, the London forces between them are very strong. The result is a strong, tough fiber. DuPont's Tyvek®, for example, is made from thin, crystalline HDPE polyethylene fibers randomly oriented and pressed together into a material resembling paper. It is lightweight, strong, and resists water, tears, punctures, and abrasion. Federal Express has been using it for years for envelopes, and builders use it to wrap new construction to prevent water and air intrusion, thereby lowering heating and cooling costs. Tyvek is also used to make limited-use protective clothing for use in hazardous environments.

■ HDPE molecules contain approximately 30,000 CH_2 units linked end to end!

■ UHMWPE molecules contain between 200,000 and 400,000 CH_2 units linked end to end!

Under the right conditions, linear polyethylene molecules can be made extremely long, yielding *ultrahigh molecular weight polyethylene* (*UHMWPE*) with molecules having molecular masses of three to six million. The fibers produced from this polymer are so strong that they are used to make bulletproof vests! Honeywell is producing an oriented polyethylene polymer it calls Spectra, which forms flexible fibers that can be woven into a strong, cut resistant fabric. It is used to make thin, lightweight liners for surgical gloves that resist cuts by scalpels, industrial work gloves, and even sails for sailboats (see Figure 23.5). Mixed with other plastics, it can be molded into strong rigid forms such as helmets for military or sporting applications.

Other good fiber-forming polymers also have long molecules with shapes that permit strong interactions between the individual polymer strands. Nylon, for example, possesses polar carbonyl groups, $>C{=}O$, and N—H bonds that form strong hydrogen bonds between the individual molecules.



Three strands of nylon 6,6 bound to each other by hydrogen bonds.

Figure 23.5 | **Spectra fibers.** Strong, lightweight sails made of Spectra fibers propelled Brad Van Liew to victory in the 2002–2003 "Around Alone" around-the-world yacht race. Van Liew sailed 31,094 miles in seven months to win the race. *(NewsCom)*

Kevlar, another type of nylon, also forms strong hydrogen bonds between polymer molecules and is very crystalline. Its strong fibers are also used to make bulletproof vests. Because the fibers are so strong, they are also used to make thin yet strong hulls of racing boats. This lightweight construction improves speed and performance without sacrificing safety.

23.6 | Biochemical Compounds

Biochemistry is the systematic study of the chemicals of living systems, their organization into cells, and their chemical interactions. Biochemicals have no life in themselves as isolated compounds, yet life has a molecular basis. Only when chemicals are organized into cells in tissues can interactions occur that enable tissue repair, cell reproduction, the generation of energy, the removal of wastes, and the management of a number of other functions. The world of living things is composed mostly of organic compounds, including many natural polymers such as proteins, starch, cellulose, and the chemicals of genes.

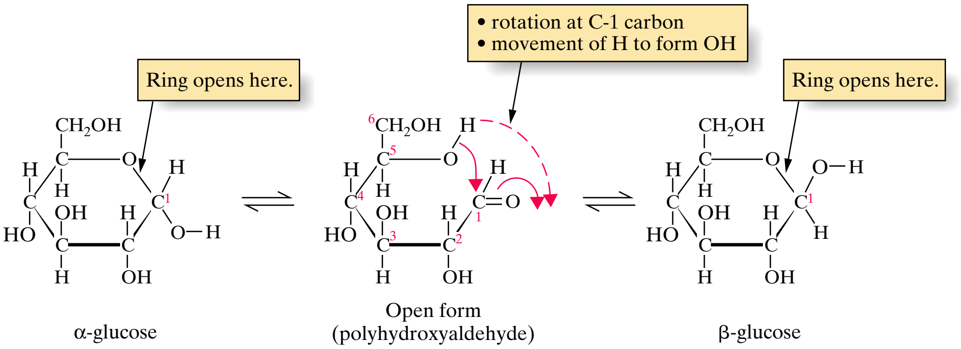
For its existence, a living system requires materials, energy, and information or "blueprints." Our focus in this section will be on the structures of substances that supply them—*carbohydrates, lipids, proteins,* and *nucleic acids*—the basic materials whose molecules, together with water and a few kinds of ions, make up cells and tissues.

■ Starch, table sugar, and cotton are all *carbohydrates*.

High-speed racing boats often are built with hulls made of Kevlar. Because of the polymer's high strength, the hulls can be made thin, thereby reducing weight and increasing speed. *(Martin Bond/ Photo Researchers)*

Carbohydrates

Most **carbohydrates,** which serve as a major source of the chemical energy we need to function, are polymers of simpler units called **monosaccharides.** The most common monosaccharide is glucose, a pentahydroxyaldehyde, and probably the most widely occurring structural unit in the entire living world. Glucose is the chief carbohydrate in blood, and

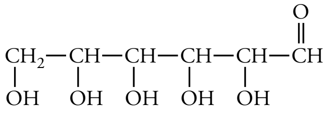


α-glucose

Open form (polyhydroxyaldehyde)

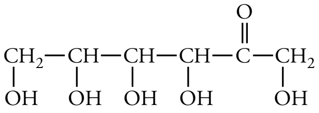
β-glucose

Figure 23.6 | **Structures of glucose.** Three forms of glucose are in equilibrium in an aqueous solution. The curved arrows in the open form show how bonds become reoriented as it closes into a cyclic form. Depending on how the CH═O group is turned at the moment of ring closure, the new OH group at C-1 takes up one of two possible orientations, α or β. In these structures, the heavier bonds are used to indicate the part of the molecule that is closer to the viewer.



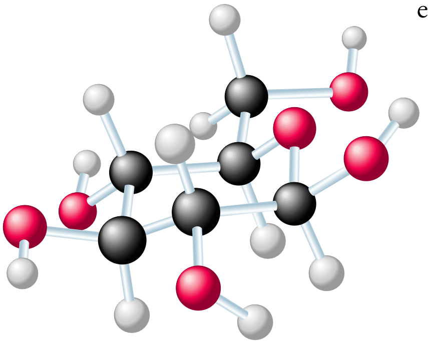
$$\underset{\text{OH}}{\underset{|}{\text{CH}_2}}-\underset{\text{OH}}{\underset{|}{\text{CH}}}-\underset{\text{OH}}{\underset{|}{\text{CH}}}-\underset{\text{OH}}{\underset{|}{\text{CH}}}-\underset{\text{OH}}{\underset{|}{\text{CH}}}-\overset{\text{O}}{\overset{\|}{\text{CH}}}$$

glucose (open-chain form)
a polyhydroxyaldehyde



$$\underset{\text{OH}}{\underset{|}{\text{CH}_2}}-\underset{\text{OH}}{\underset{|}{\text{CH}}}-\underset{\text{OH}}{\underset{|}{\text{CH}}}-\underset{\text{OH}}{\underset{|}{\text{CH}}}-\overset{\text{O}}{\overset{\|}{\text{C}}}-\underset{\text{OH}}{\underset{|}{\text{CH}_2}}$$

fructose (open-chain form)
a polyhydroxyketone



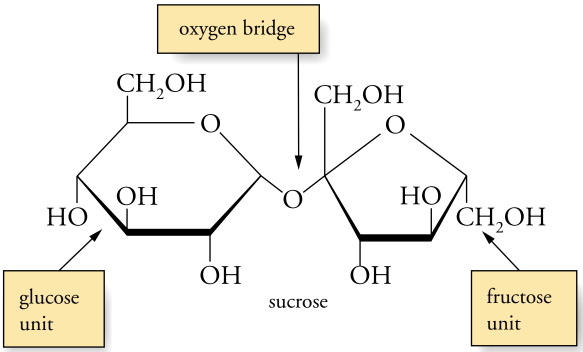
Because of the tetrahedral arrangement of atoms around each carbon, the six-membered rings of the cyclic forms of monosaccharides are not actually flat, as implied by the structural formulas we've drawn for them. The β-glucose molecule, for example, has the structure shown above.

it provides the building unit for such important polysaccharides as cellulose and starch. Fructose, a pentahydroxyketone, is produced together with glucose when we digest table sugar. Honey is also rich in fructose.

When dissolved in water, the molecules of most monosaccharides exist in an equilibrium involving more than one structure. Glucose, for example, exists as two cyclic forms and one open-chain form in equilibrium in water (see Figure 23.6). The open-chain form, the only one with a free aldehyde group, is represented by less than 0.1% of the solute molecules. Yet, the solute in an aqueous glucose solution still gives the reactions of a polyhydroxyaldehyde. This is possible because the equilibrium between this form and the two cyclic forms shifts rapidly to supply more of any of its members when a specific reaction occurs to just one (in accordance with Le Châtelier's principle).

Disaccharides

Carbohydrates whose molecules are split into two monosaccharide molecules by reacting with water are called **disaccharides.** *Sucrose* (table sugar, cane sugar, or beet sugar) is an example, and its hydrolysis gives glucose and fructose.



sucrose

To simplify, let's represent sucrose as Glu—O—Fru, where Glu is a glucose unit and Fru is a fructose unit, both joined by an oxygen bridge, —O—. The hydrolysis of sucrose, the chemical reaction by which we digest it, can thus be represented as follows.[3]

$$\underset{\text{sucrose}}{\text{Glu—O—Fru}} + \text{H}_2\text{O} \xrightarrow[\text{hydrolysis}]{\text{digestion}} \text{glucose} + \text{fructose}$$

Lactose (milk sugar) hydrolyzes to glucose and galactose (Gal), an isomer of glucose, and this is the reaction by which we digest lactose.

$$\underset{\text{lactose}}{\text{Gal—O—Glu}} + \text{H}_2\text{O} \xrightarrow[\text{hydrolysis}]{\text{digestion}} \text{galactose} + \text{glucose}$$

---

[3] Considerable detail is lost with the simplified structure of sucrose (and other carbohydrates like it to come). We leave the details, however, to other books because we seek a broader view.

Polysaccharides

Plants store glucose units for energy needs in molecules of **starch**, a type of large polymeric sugar molecule called a **polysaccharide**. Starch is found often in seeds and tubers (e.g., potatoes). It consists of two kinds of glucose polymers. The structurally simpler kind is *amylose*, which makes up roughly 20% of starch. We may represent its structure as follows, where O is the oxygen bridge linking glucose units.

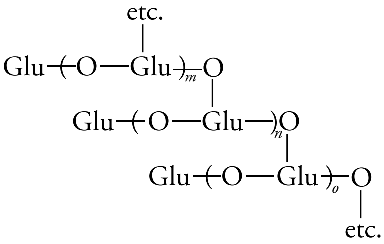
$$\text{Glu}\!-\!\left(\text{O}-\text{Glu}\right)_n\!-\!\text{OH}$$

amylose; n is very large

The average amylose molecule has over 1000 glucose units linked together by oxygen bridges. These are the sites that are attacked and broken when water reacts with amylose during digestion. Molecules of glucose are released and are eventually delivered into circulation in the blood stream.

$$\text{Amylose} + n\text{H}_2\text{O} \xrightarrow[\text{(hydrolysis)}]{\text{digestion}} n \text{ glucose}$$

The bulk of starch is made up of *amylopectin*, whose molecules are even larger than those of amylose. The amylopectin molecule consists of several amylose molecules linked by oxygen bridges from the end of one amylose unit to a site somewhere along the "chain" of another amylose unit.



Amylopectin (m, n, and o are large numbers)

Molecular masses ranging from 50,000 to several million are observed for amylopectin samples from the starches of different plant species. (A molecular mass of 1 million corresponds to about 6000 glucose units.)

Animals store glucose units for energy as **glycogen,** a polysaccharide with a molecular structure very similar to that of amylopectin. When we eat starchy foods and deliver glucose molecules into the bloodstream, any excess glucose not needed to maintain a healthy concentration in the blood is removed from circulation by particular tissues, like the liver and muscles. Liver and muscle cells convert glucose to glycogen. Later, during periods of high energy demand or fasting, glucose units are released from the glycogen reserves so that the concentration of glucose in the blood stays high enough for the needs of the brain and other tissues.

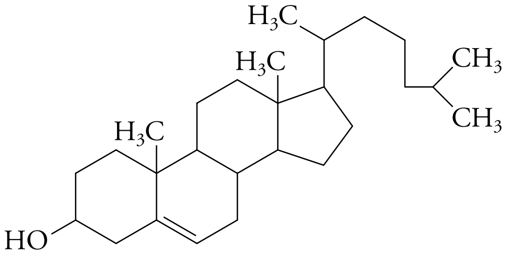
Cellulose

Cellulose is a polymer of glucose, much like amylose, but with the oxygen bridges oriented with different geometries. We lack the enzyme needed to hydrolyze its oxygen bridges, so we are unable to use cellulose materials like lettuce for food, only for fiber. Animals, such as cows that eat grass and leaves, have bacteria living in their digestive tracts that convert cellulose into small molecules, which the host organism then appropriates for its own use.

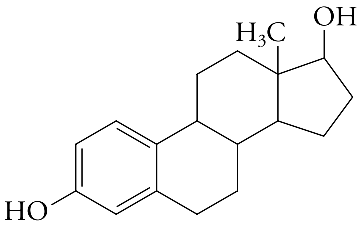
■ Cellulose is the chief material in a plant cell wall, and it makes up about 100% of cotton.

Lipids

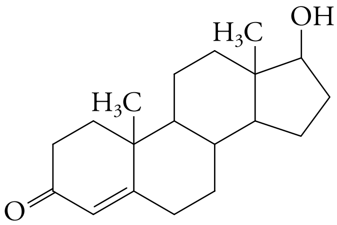
Lipids are natural products that are water insoluble, but tend to dissolve in nonpolar solvents such as diethyl ether or benzene. The lipid family is huge because the only structural requirement is that lipid molecules be relatively nonpolar with large segments that are entirely hydrocarbon-like. For example, the lipid family includes cholesterol as well as sex hormones, like estradiol and testosterone. You can see from their structures how largely hydrocarbon-like they are.



cholesterol



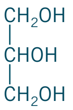
estradiol
(a female sex hormone)



testosterone
(a male sex hormone)

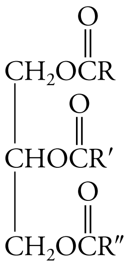
Triacylglycerols

The lipid family also includes the edible fats and oils in our diets—substances such as olive oil, corn oil, butterfat, and lard. These are **triacylglycerols**, which are esters between glycerol, an alcohol with three OH groups, and any three of several long-chain carboxylic acids.



$$\begin{array}{l}\mathrm{CH_2OH}\\ |\\ \mathrm{CHOH}\\ |\\ \mathrm{CH_2OH}\end{array}$$

glycerol



$$\begin{array}{l}\mathrm{CH_2O\overset{O}{\overset{\|}{C}}R}\\ |\\ \mathrm{CHO\overset{O}{\overset{\|}{C}}R'}\\ |\\ \mathrm{CH_2O\overset{O}{\overset{\|}{C}}R''}\end{array}$$

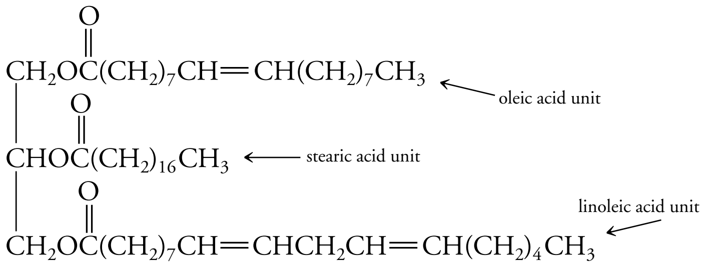
(general structural
features)



$$\begin{array}{l}\mathrm{CH_2O\overset{O}{\overset{\|}{C}}(CH_2)_7CH{=}CH(CH_2)_7CH_3}\\ |\\ \mathrm{CHO\overset{O}{\overset{\|}{C}}(CH_2)_{16}CH_3}\\ |\\ \mathrm{CH_2O\overset{O}{\overset{\|}{C}}(CH_2)_7CH{=}CHCH_2CH{=}CH(CH_2)_4CH_3}\end{array}$$

triacylglycerol—typical molecule present
in a vegetable oil

The carboxylic acids used to make triacylglycerols are called **fatty acids** and generally have just one carboxyl group on an unbranched chain with an even number of carbon atoms (Table 23.4). Their long hydrocarbon chains make triacylglycerols mostly like hydrocarbons in physical properties, including insolubility in water. Many fatty acids have alkene groups.

Triacylglycerols obtained from vegetable sources, like olive oil, corn oil, and peanut oil, are called *vegetable oils* and are liquids at room temperature. Triacylglycerols from animal sources, like lard and tallow, are called *animal fats* and are solids at room temperature. The vegetable oils generally have more alkene double bonds per molecule than animal fats, and so are said to be *polyunsaturated*. The double bonds are usually cis, and so the molecules

■ Cooking oils are advertised as *polyunsaturated* because of their several alkene groups per molecule.

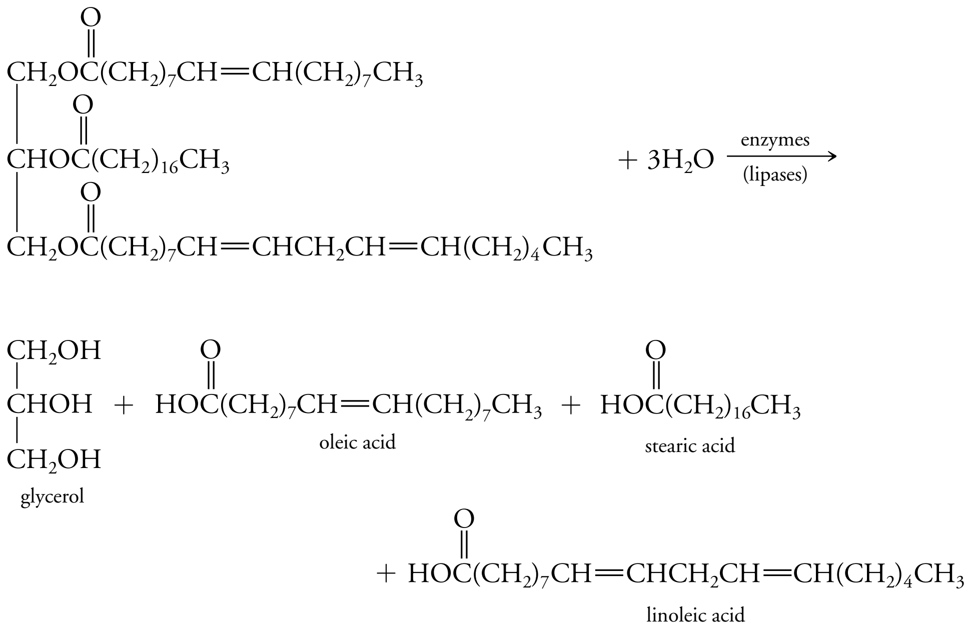
Table 23.4 Common Fatty Acids

Fatty Acid	Number of Carbon Atoms	Structure	Melting Point (°C)
Myristic acid	14	$\mathrm{CH_3(CH_2)_{12}CO_2H}$	54
Palmitic acid	16	$\mathrm{CH_3(CH_2)_{14}CO_2H}$	63
Stearic acid	18	$\mathrm{CH_3(CH_2)_{16}CO_2H}$	70
Oleic acid	18	$\mathrm{CH_3(CH_2)_7CH{=}CH(CH_2)_7CO_2H}$	4
Linoleic acid	18	$\mathrm{CH_3(CH_2)_4CH{=}CHCH_2CH{=}CH(CH_2)_7CO_2H}$	−5
Linolenic acid	18	$\mathrm{CH_3CH_2CH{=}CHCH_2CH{=}CHCH_2CH{=}CH(CH_2)_7CO_2H}$	−11

are kinked, making it more difficult for them to nestle close together, experience London forces, and so be in the solid state.

Digestion of Triacylglycerols

We digest the triacylglycerols by hydrolysis, meaning by their reaction with water. Our digestive juices in the upper intestinal tract have enzymes called *lipases* that catalyze these reactions. For example, the complete digestion of the triacylglycerol shown previously occurs by the following reaction:



$$\begin{array}{l} \mathrm{CH_2O\overset{O}{\overset{\|}{C}}(CH_2)_7CH{=}CH(CH_2)_7CH_3} \\ \mathrm{CHO\overset{O}{\overset{\|}{C}}(CH_2)_{16}CH_3} \\ \mathrm{CH_2O\overset{O}{\overset{\|}{C}}(CH_2)_7CH{=}CHCH_2CH{=}CH(CH_2)_4CH_3} \end{array} + 3\mathrm{H_2O} \xrightarrow[\text{(lipases)}]{\text{enzymes}}$$

$$\underset{\text{glycerol}}{\begin{array}{l} \mathrm{CH_2OH} \\ \mathrm{CHOH} \\ \mathrm{CH_2OH} \end{array}} + \underset{\text{oleic acid}}{\mathrm{HO\overset{O}{\overset{\|}{C}}(CH_2)_7CH{=}CH(CH_2)_7CH_3}} + \underset{\text{stearic acid}}{\mathrm{HO\overset{O}{\overset{\|}{C}}(CH_2)_{16}CH_3}}$$

$$+ \underset{\text{linoleic acid}}{\mathrm{HO\overset{O}{\overset{\|}{C}}(CH_2)_7CH{=}CHCH_2CH{=}CH(CH_2)_4CH_3}}$$

Actually, the *anions* of the acids form, because the medium in which lipid digestion occurs is basic.

When the hydrolysis of a triacylglycerol is carried out in the presence of sufficient base so as to release the fatty acids as their anions, the reaction is called *saponification*. A mixture of the salts of long-chain fatty acids is what makes up ordinary *soap*.

Hydrogenation of Vegetable Oils

Vegetable oils are generally less expensive to produce than butterfat, but because the oils are liquids, few people care to use them as bread spreads. Animal fats, like butterfat, are solids at room temperature, and vegetable oils differ from animal fats only in the number of carbon–carbon double bonds per molecule. Simply adding hydrogen to the double bonds of a vegetable oil, therefore, changes the lipid from a liquid to a solid.

■ Hydrogenation of a vegetable oil will add hydrogen atoms to both *cis* and *trans* isomers and result in a straight chain, saturated, molecule that maximizes the London attractive forces.

Partial hydrogenation of a vegetable oil can lead to rearrangement of the atoms around the double bonds from cis to trans. The resulting products are known as *trans fats*. Because ingestion of trans fats has been associated with coronary artery disease, food product labels are now required to show the amounts of these fats in the food. Fast-food chains such as McDonalds, Wendy's, KFC, and Taco Bell have switched from using trans fat oils for cooking their French fries. In New York City, trans fats are banned from all restaurants.

Cell Membranes in Animals

The lipids involved in the structures of cell membranes in animals are not triacylglycerols. Some are diacylglycerols with the third site on the glycerol unit taken up by an attachment to a phosphate unit. This, in turn, is joined to an amino alcohol unit by an ester-like network. The phosphate unit carries one negative charge, and the amino unit has a positive charge. These lipids are called *glycerophospholipids*. Lecithin is one example; it is used in cooking as an emulsifier.

■ The amino alcohol unit in lecithin is contributed by choline, a cation:

$$HOCH_2CH_2\overset{+}{N}(CH_3)_3$$

Ethanolamine (in its protonated form),

$$HOCH_2CH_2NH_3^+$$

is another amino alcohol that occurs in phospholipids.

Glycerophospholipid symbol

The glycerophospholipids illustrate that it is possible for lipid molecules to carry polar, even ionic sites, and still not be very soluble in water. The combination of both nonpolar and polar or ionic units within the same molecule enable the glycerophospholipids and similar substances to be major building units for the membranes of animal cells.

The purely hydrocarbon-like portions of a glycerophospholipid molecule (the long R groups contributed by the fatty acid units) are **hydrophobic** ("water fearing;" they avoid water molecules). The portions bearing the electrical charges are **hydrophilic** ("water loving;" they are attracted to water molecules). In an aqueous medium, therefore, the molecules of a glycerophospholipid aggregate in a way that minimizes the exposure of the hydrophobic side chains to water and maximizes contact between the hydrophilic sites and water. These interactions are roughly what take place when glycerophospholipid molecules aggregate to form the *lipid bilayer* membrane of an animal cell (Figure 23.7). The hydrophobic side chains intermingle in the center of the layer where water molecules do not occur. The hydrophilic groups are exposed to the aqueous medium inside and outside of the cell. Not shown in Figure 23.7 are cholesterol and cholesterol ester molecules, which help to stiffen the membranes. Thus cholesterol is essential to the cell membranes of animals.

Cell membranes also include protein units, which provide several services. Some are molecular recognition sites for molecules such as hormones and neurotransmitters. Others provide channels for the movements of ions, like Na^+, K^+, Ca^{2+}, Cl^-, HCO_3^-, and others into or out of the cell. Some are channels for the transfer of small organic molecules, like glucose.

■ *Neurotransmitters* are small molecules that travel between the end of one nerve cell and the surface of the next to transmit the nerve impulse.

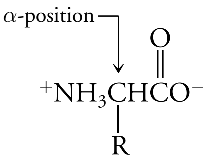
Proteins

Proteins are a large family of substances that make up about half of the human body's dry weight. They are found in all cells and serve as enzymes, hormones, and neurotransmitters. They carry oxygen in the blood stream as well as some of the waste products of metabolism. No other group of compounds has such a variety of functions in living systems.

The dominant structural units of **proteins** are macromolecules called **polypeptides**, which are made from a set of monomers called **α-amino acids.** Most protein molecules include, besides their polypeptide units, small organic molecules or metal ions, and the whole protein lacks its characteristic biological function without these species.

The monomer units for polypeptides are a group of about 20 α-amino acids, all of which have structural features in common. Some examples of the set of 20 amino acids used to make proteins are given below. The symbol R stands for an *amino acid side chain.* All amino acids are known by their common names and each also has been given a three-letter symbol.



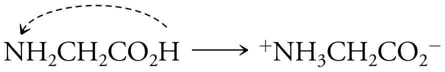
$$^{+}NH_3\overset{\downarrow}{C}H(R)\overset{O}{\overset{\|}{C}}O^{-}$$

α-amino acid, general structural features

R = H, glycine (Gly)
= CH_3, alanine (Ala)
= CH_2— , phenylalanine (Phe)
= $CH_2CH_2CO_2H$, glutamic acid (Glu)
= $CH_2CH_2CH_2CH_2NH_2$, lysine (Lys)
= CH_2SH, cysteine (Cys)

The simplest amino acid is glycine, for which the "side chain" is H.

Glycine, like all of the amino acids in their pure states, exists as a *dipolar ion.* Such an ion results from an internal self-neutralization, by the transfer of a proton from the proton-donating carboxyl group to the proton-accepting amino group.

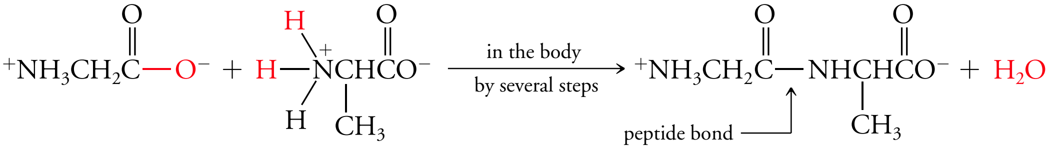


$$NH_2CH_2CO_2H \longrightarrow {}^{+}NH_3CH_2CO_2{}^{-}$$

glycine — glycine, dipolar ionic form

Polypeptides

Polypeptides are copolymers of the amino acids. The carboxyl group of one amino acid becomes joined to the amino group of another by means of an amide bond—the same kind of carbonyl–nitrogen bond found in nylon (page 1075), but here in a peptide is called a **peptide bond.** Let's see how two amino acids, glycine and alanine, can become linked by a (multistep) splitting out of water.

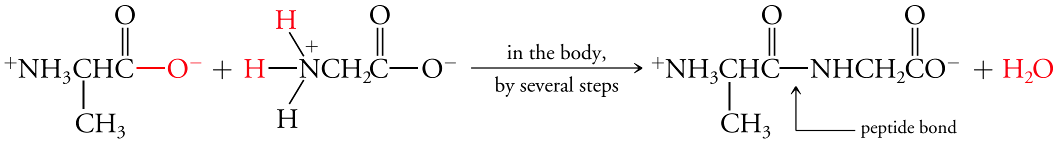


$$^{+}NH_3CH_2\overset{O}{\overset{\|}{C}}—O^{-} + H—\overset{+}{N}H_2\underset{CH_3}{CH}\overset{O}{\overset{\|}{C}}O^{-} \xrightarrow[\text{by several steps}]{\text{in the body}} {}^{+}NH_3CH_2\overset{O}{\overset{\|}{C}}—NH\underset{CH_3}{CH}\overset{O}{\overset{\|}{C}}O^{-} + H_2O$$

glycine (Gly) — alanine (Ala) — glycylalanine (Gly-Ala)

The product of this reaction, glycylalanine, is an example of a *dipeptide.* (Biochemists often use the three-letter symbols for the amino acids to describe the *structural* formulas of such products.)

We could have taken glycine and alanine in different roles and written the equation for the formation of a different dipeptide, Ala-Gly.



$${}^+\mathrm{NH_3}\underset{\mathrm{CH_3}}{\mathrm{CH}}\overset{\mathrm{O}}{\overset{\|}{\mathrm{C}}}-\mathrm{O^-} + \mathrm{H}-\overset{\mathrm{H}}{\underset{\mathrm{H}}{\overset{+}{\mathrm{N}}}}\mathrm{CH_2}\overset{\mathrm{O}}{\overset{\|}{\mathrm{C}}}-\mathrm{O^-} \xrightarrow[\text{by several steps}]{\text{in the body,}} {}^+\mathrm{NH_3}\underset{\mathrm{CH_3}}{\mathrm{CH}}\overset{\mathrm{O}}{\overset{\|}{\mathrm{C}}}-\mathrm{NHCH_2}\overset{\mathrm{O}}{\overset{\|}{\mathrm{C}}}\mathrm{O^-} + \mathrm{H_2O}$$

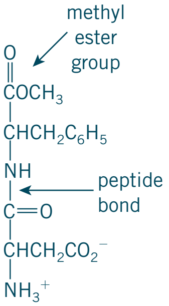
alanine (Ala) glycine (Gly) alanylglycine (Ala-Gly)

The formation of these two dipeptides is like the formation of two 2-letter words from the letters N and O. Taken in one order we get NO; in the other, ON. They have entirely different meanings, yet are made of the same pieces.

Notice that each dipeptide, Gly-Ala and Ala-Gly, has a CO_2^- at one end of the chain and a $^+NH_3$ group at the other end. Each end of a dipeptide molecule, therefore, could form yet another peptide bond involving any of the 20 amino acids. For example, if glycylalanine were to combine with phenylalanine (Phe), two different *tripeptides* could form with the sequences Gly-Ala-Phe or Phe-Gly-Ala. Each of these tripeptides has a CO_2^- at one end and a $^+NH_3$ at the other end. Thus, you can see how very long sequences of amino acid units can be joined together.

As the length of a polypeptide chain grows, the number of possible combinations of amino acids becomes astronomical. For example, with just the three amino acids we've used (Gly, Ala, and Phe), six different polypeptide sequences are possible that differ only in the three side chains, H, CH_3, and $CH_2C_6H_5$ that are located at the α-carbon atoms.

■ The artificial sweetener aspartame (NutraSweet®) is the methyl ester of a dipeptide.



aspartame

Protein Structures

Many proteins consist of a single polypeptide. Most proteins, however, involve assemblies of two or more polypeptides. These are identical in some proteins, but in others, the aggregating polypeptides are different. Moreover, a relatively small organic molecule may be included in the aggregation, and a metal ion is sometimes present, as well. Thus, the terms "protein" and "polypeptide" are not synonyms. Hemoglobin, for example, has all of the features just described (Figure 23.8). It is made of four polypeptides—two similar pairs—and four molecules of heme, the organic compound that causes the red color of blood. Heme, in turn, holds an iron(II) ion. The *entire* package is the protein, hemoglobin. If one piece is missing or altered in any way—for example, if iron occurs as Fe^{3+} instead of Fe^{2+}—the substance is not hemoglobin, and it does not transport oxygen in the blood.

■ Hemoglobin is the oxygen carrier in blood.

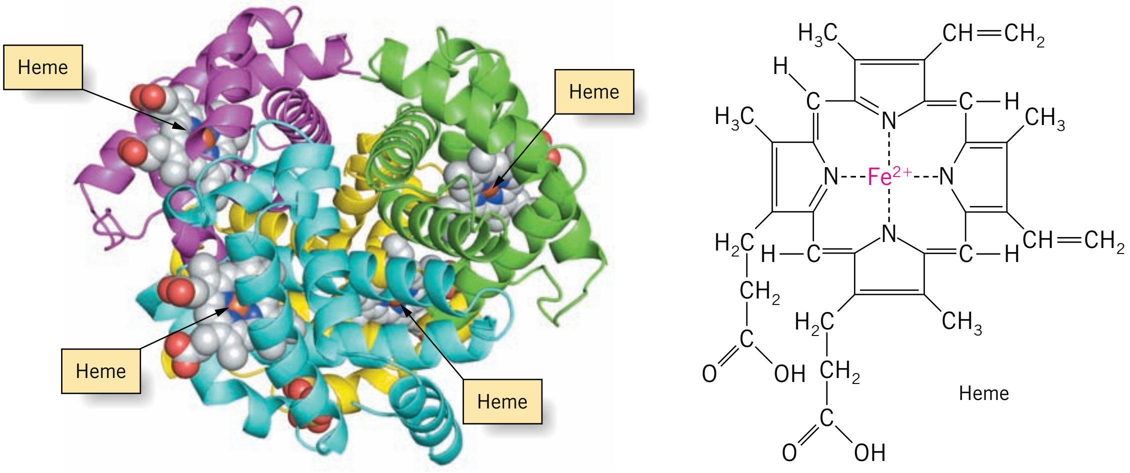


Figure 23.8 | **Hemoglobin.** Its four polypeptide chains, each shown as different colored ribbons, twist and bend around the four embedded heme units. Each heme unit contains an Fe^{2+} ion in its center that is able to bind to O_2.

Notice in Figure 23.8 how the strands of each polypeptide unit in hemoglobin are coiled and that the coils are kinked and twisted. Such shapes of polypeptides are determined by the amino acid sequence, because the side chains are of different sizes and some are hydrophilic and others are hydrophobic. Polypeptide molecules become twisted and coiled in whatever way minimizes the contact of hydrophobic groups with the surrounding water and maximizes the contacts of hydrophilic groups with water molecules. In addition, hydrogen bonding between N—H and C═O groups in neighboring loops help hold the shapes of the helices.

The final shape of a protein, called its *native form,* is as critical to its ability to function as anything else about its molecular architecture. For example, just the exchange of one side-chain R group by another changes the shape of hemoglobin and causes a debilitating condition known as sickle-cell anemia.

■ In one of the subunits of the hemoglobin in those with sickle-cell anemia, an isopropyl group, —$CH(CH_3)_2$, is a side-chain where a —$CH_2CH_2CO_2H$ side-chain should be.

Enzymes

The catalysts in living cells are called **enzymes**, and virtually all are proteins. Some enzymes require a metal ion, such as Mn^{2+}, Co^{2+}, Cu^{2+}, or Zn^{2+}, all of which are on the list of the *trace elements* that must be in a good diet. Some enzymes also require molecules of the B vitamins to be complete enzymes.

Some of our most dangerous poisons work by deactivating enzymes, often those needed for the transmission of nerve signals. For example, the botulinum toxin that causes botulism, a deadly form of food poisoning, deactivates an enzyme in the nervous system. Heavy metal ions, like Hg^{2+} or Pb^{2+}, are poisons because they also deactivate enzymes.

■ Heavy metal ions bond to the HS groups of cysteine side-chains in polypeptides.

23.7 | Nucleic Acids

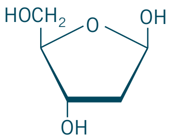
The polypeptides of an organism are made under the chemical direction of a family of compounds called the *nucleic acids*. Both the similarities and the uniqueness of every species as well as every individual member of a species depend on structural features of these compounds.

DNA and RNA

The **nucleic acids** occur as two broad types: **RNA**, or ribonucleic acids, and **DNA**, or deoxyribonucleic acids. DNA is the actual chemical of a gene and provides the chemical basis through which we inherit all of our characteristics.

The main chains or "backbones" of DNA molecules consist of alternating units contributed by phosphoric acid and a sugar molecule—a monosaccharide—as shown in Figure 23.9. In RNA, the monosaccharide is ribose (hence the R in RNA). In DNA, the monosaccharide is deoxyribose (*deoxy* means "lacking an oxygen unit"). Thus, both DNA

■ 
ribose



deoxyribose

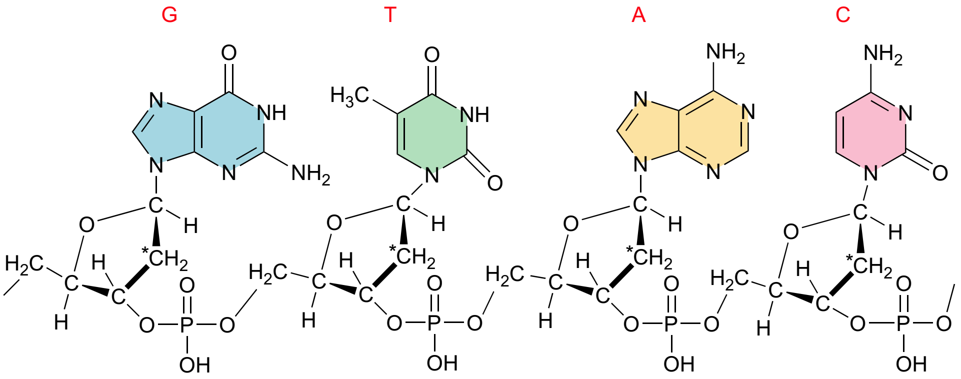


Figure 23.9 | **Nucleic acids.**

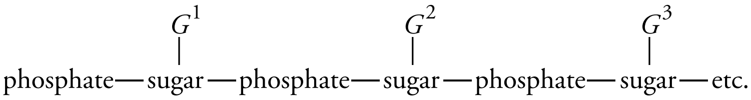
A segment of a DNA chain featuring each of the four DNA bases. When the sites marked by asterisks each carry an OH group, the main "backbone" would be that of RNA. In RNA, U would replace T.

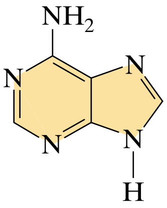
and RNA have the following systems, where *G* stands for *group* and each *G* unit represents a unique nucleic acid side chain.



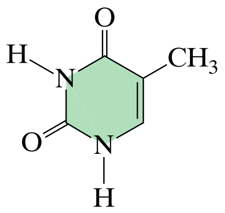
$$\text{phosphate}-\overset{\overset{\displaystyle G^1}{|}}{\text{sugar}}-\text{phosphate}-\overset{\overset{\displaystyle G^2}{|}}{\text{sugar}}-\text{phosphate}-\overset{\overset{\displaystyle G^3}{|}}{\text{sugar}}-\text{etc.}$$

Backbone system in all nucleic acids is many thousands of repeating units long.
In DNA, the sugar is deoxyribose.
In RNA, the sugar is ribose.

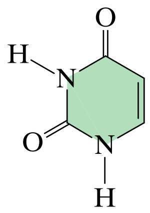
The side chains, *G*, are all heterocyclic amines whose molecular shapes have much to do with their function. Being amines, which are basic in water, they are referred to as the *bases* of the nucleic acids and are represented by single letters—A for adenine, T for thymine, U for uracil, G for guanine, and C for cytosine.



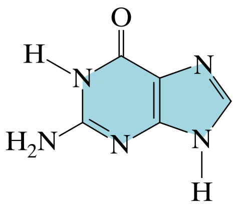
adenine
A



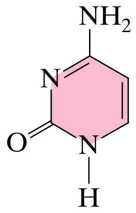
thymine
T



uracil
U



guanine
G



cytosine
C

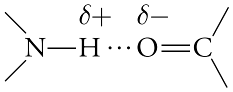
In DNA, the bases are A, T, G, and C; in RNA they are A, U, G, and C. These few bases are the "letters" of the genetic alphabet. Amazingly, the messages describing our entire genetic makeup are composed with just four "letters"—A, T, G, and C.

The DNA Double Helix

■ Crick and Watson shared the 1962 Nobel-Prize in Physiology or Medicine with Maurice Wilkins, using X-ray data from Rosalind Franklin to deduce the helical structure of DNA. The structure of DNA is illustrated in Figure 12.9 on page 534.

In 1953, F. H. C. Crick of England and J. D. Watson, an American, deduced that DNA occurs in cells as two intertwined, oppositely running strands of molecules coiled like a spiral staircase and called the **DNA double helix**. Hydrogen bonds help to hold the two strands side by side, but other factors are also involved.

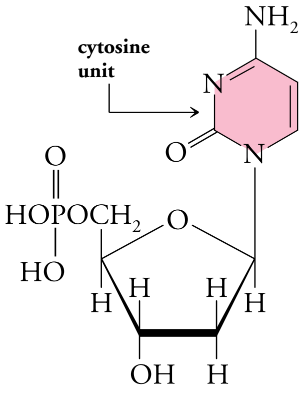
The bases have N—H and O═C groups, which enable hydrogen bonds (···) to form between them.



$$\text{N}-\overset{\delta+}{\text{H}}\cdots\overset{\delta-}{\text{O}}=\text{C}$$

However, the bases with the best "matching" molecular geometries for maximum hydrogen bonding occur only as particular *pairs* of bases. The functional groups of each pair are in exactly the right locations in their molecules to allow hydrogen bonds between pair members. In DNA, A pairs only with T, never with G or C (see Figure 23.10). Similarly, C pairs only with G, never with A or T. Thus, opposite every G on one strand in a DNA double helix, a C occurs on the other. Opposite every A on one strand in DNA, a T is found on the other.

Adenine (A) can also pair with uracil (U), but U occurs in RNA. The A-to-U pairing is an important factor in the work of RNA.

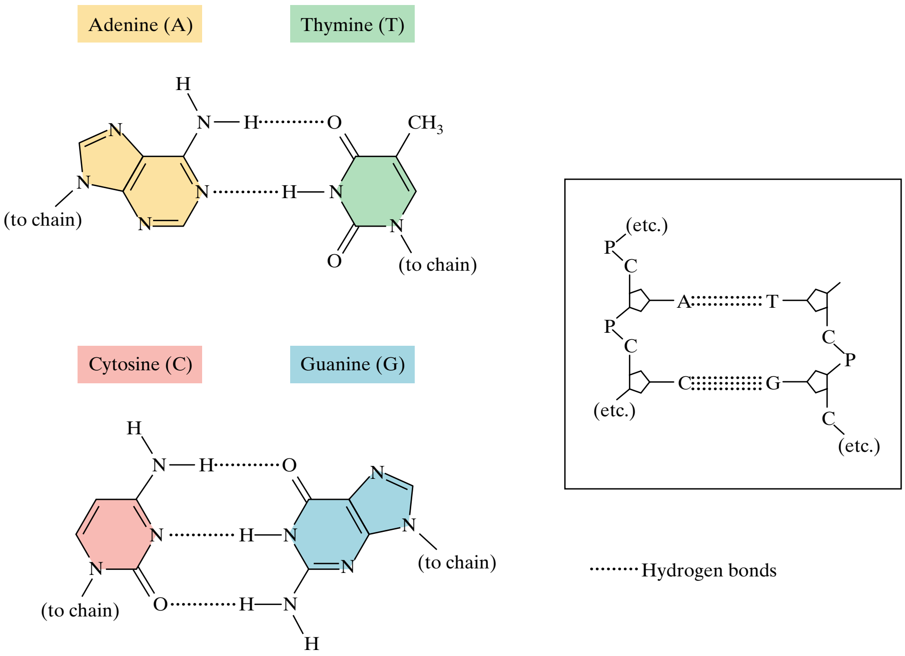


a typical nucleotide, one using cytosine as its side chain

DNA Replication

Prior to cell division, the cell produces duplicate copies of its DNA so that each daughter cell will have a complete set. Such reproductive duplication is called DNA **replication.**

The accuracy of DNA replication results from the limitations of the base pairings: A only with T, and C only with G (Figure 23.11). The unattached letters, A, T, G, and C,



Adenine (A)
Thymine (T)
Cytosine (C)
Guanine (G)
(to chain)
(etc.)
Hydrogen bonds

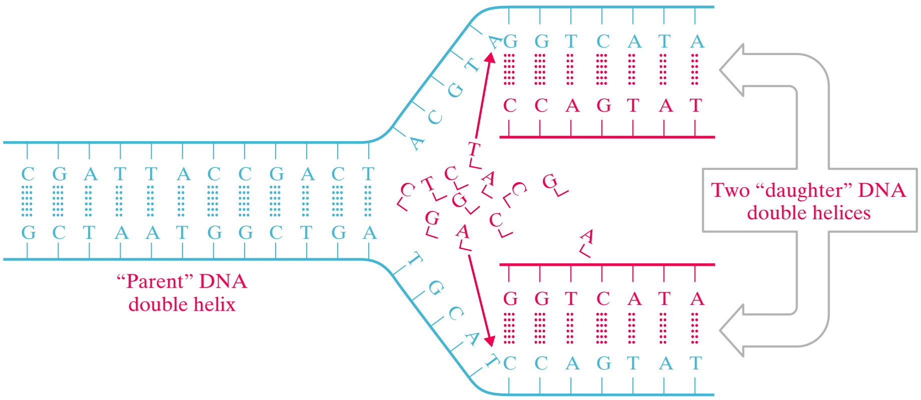
Figure 23.10 | **Base pairing in DNA.** The hydrogen bonds are indicated by dotted lines.

in Figure 23.11 here represent not just the bases but the whole monomer molecules of DNA. The monomers are called *nucleotides* and are molecules made of a phosphate–sugar unit bonded to one particular base (see the illustration in the margin). The nucleotides are made by the cell and are present in the cellular "soup."

An enzyme catalyzes each step of replication. As replication occurs, the two strands of the parent DNA double helix separate, and the monomers for new strands assemble along the exposed single strands. Their order of assembling is completely determined by the specificity of base pairing. For example, a base such as T on a parent strand can accept only a nucleotide with the base A. Two daughter double helixes result that are identical to the parent, and each carries one strand from the parent. One new double helix goes to one daughter cell and the second goes to the other.

Genes and Polypeptide Synthesis

A single human gene has between 1000 and 3000 bases, but they do not occur continuously on a DNA molecule. In multicelled organisms, a gene is neither a whole DNA molecule nor a continuous sequence in one. A single gene consists of the totality of particular *segments* of a DNA chain that, taken together, carry the necessary genetic instruction for a particular polypeptide.



C G A T T A C C G A C T
G C T A A T G G C T G A
"Parent" DNA double helix
Two "daughter" DNA double helices
G G T C A T A
C C A G T A T

Figure 23.11 | **Base pairing and replication of DNA.**

Each polypeptide in a cell is made under the direction of its own gene. In broad outline, the steps between a gene and a polypeptide occur as follows.

$$\text{DNA} \xrightarrow{\text{transcription}} \text{RNA} \xrightarrow{\text{translation}} \text{Polypeptide}$$

gene	(The genetic message is read off in the cell nucleus and transferred to RNA.)	(The genetic message, now on RNA outside the nucleus, is used to direct the synthesis of a polypeptide.)

The step labeled **transcription** accomplishes just that—the genetic message, represented by a sequence of bases on DNA, is transcribed into a *complementary* sequence of bases on RNA, but U, not T, is on the RNA. **Translation** means the conversion of the base sequence on RNA into a side-chain sequence on a new polypeptide. It is like translating from one language (the DNA/RNA base sequences) to another language (the polypeptide side-chain sequence).

The translation step in polypeptide synthesis involves several steps and several different kinds of RNA. In the process, the cell tells which amino acid unit must come next in a growing polypeptide chain by means of a code that relates unique groups of three nucleic acid bases, called **codons**, to specific amino acids.

Which amino acid goes with which codon constitutes the **genetic code,** which enables the cell to translate from the four-letter RNA alphabet (A, U, G, and C) to the 20-letter alphabet of amino acids (the amino acid side chains). One of the most remarkable features of the code is that it is essentially universal. The codon specifying alanine in humans, for example, also specifies alanine in the genetic machinery of bacteria, aardvarks, camels, rabbits, and stinkbugs. Our chemical kinship with the entire living world is profound (even humbling).

Summary

Organic Compounds. **Organic chemistry** is the study of the covalent compounds of carbon, except for its oxides, carbonates, bicarbonates, and a few others. **Functional groups** attached to nonfunctional and hydrocarbon-like groups are the basis for the classification of organic compounds. Members of a family have the same kinds of chemical properties. Their physical properties are a function of the relative proportions of functional and nonfunctional groups. Opportunities for hydrogen bonding strongly influence the boiling points and water solubilities of compounds with OH or NH groups. Organic compounds exhibit isomerism because often there is more than one possible structure corresponding to a given molecular formula. Molecules containing an **asymmetric carbon atom** exhibit chirality.

Saturated Hydrocarbons. The **alkanes—saturated** compounds found chiefly in petroleum—are the least polar and the least reactive of the organic families. Their carbon skeletons can exist as **straight chains, branched chains,** or **rings.** When they are *open-chain*, there is free rotation about single bonds. Rings can include heteroatoms, but **heterocyclic compounds** are not hydrocarbons.

By the IUPAC rules, the names of alkanes end in *-ane*. A prefix denotes the carbon content of the parent chain, the longest continuous chain, which is numbered from whichever end is nearest a branch. The **alkyl groups** are alkanes minus a hydrogen.

Alkanes in general do not react with strong acids or bases. At high temperatures, their molecules crack to give H_2 and unsaturated compounds.

Unsaturated Hydrocarbons. The lack of free rotation at a carbon–carbon double bond makes **geometric isomerism** possible. The pair of electrons of a π bond makes alkenes act as Brønsted bases, enabling alkenes to undergo **addition reactions** with strong binary acids, or with water in the presence of an acid catalyst). Alkenes also add hydrogen (in the presence of a metal catalyst). Bromine and chlorine add to alkenes under mild, uncatalyzed conditions. Strong oxidizing agents, like ozone, readily attack alkenes and break their molecules apart.

Aromatic hydrocarbons, like benzene, do not give the addition reactions shown by alkenes. Instead, they undergo **substitution reactions** that leave the energy lowering, π electron network intact. In the presence of suitable catalysts, benzene undergoes these reactions with chlorine, bromine, nitric acid, and sulfuric acid.

Compounds Containing Oxygen. The **alcohols,** ROH, and the **ethers,** ROR′, are alkyl derivatives of water. Ethers have almost as few chemical properties as alkanes. Alcohols undergo an **elimination reaction** that splits out H_2O and changes them to alkenes. Concentrated strong binary acids, like HI, react with alcohols by a **substitution reaction,** which replaces the OH group by halogen. Oxidizing agents convert alcohols of the type RCH_2OH first into aldehydes and then into carboxylic acids. Oxidizing agents convert alcohols of the type R_2CHOH into ketones. Alcohols form esters with carboxylic acids.

Aldehydes, $RCH{=}O$, among the most easily oxidized organic compounds, are oxidized to carboxylic acids. **Ketones,**

RCOR′, strongly resist oxidation. Aldehydes and ketones add hydrogen to make alcohols.

The **carboxylic acids,** RCO_2H, are weak acids but neutralize strong bases. Their anions are Brønsted bases. Carboxylic acids can also be changed to esters by heating them with alcohols.

Esters, RCO_2R', react with water to give back their parent acids and alcohols. When aqueous base is used for hydrolysis, the process is called *saponification* and the products are the salts of the parent carboxylic acids as well as alcohols.

Derivatives of Ammonia. The simple **amines,** RNH_2, as well as their more substituted relatives, RNHR′ and RNR′R″, are organic derivatives of ammonia and thus are weak bases that can neutralize strong acids. The conjugate acids of amines are good proton donors and can neutralize strong bases.

The simple **amides,** $RCONH_2$, can be made from acids and ammonia, and they can be hydrolyzed back to their parent acids and trivalent nitrogen compounds. The amides are not basic.

Polymers. **Polymers,** which are **macromolecules,** are made up of a very large number of atoms in which a small characteristic feature repeats over and over many times. **Polypropylene,** a **chain-growth** or **addition polymer** that consists of a hydrocarbon **backbone** with a methyl group, CH_3, attached to every other carbon, is formed by **polymerization** of the **monomer** propylene. Polyethylene and polystyrene, which are also addition polymers, are formed from ethylene and styrene, respectively. **Condensation polymers (step-growth polymers)** are formed by elimination of a small molecule such as H_2O or CH_3OH from two monomer units accompanied by the formation of a covalent bond between the monomers. **Nylons** and **polyesters** are **copolymers** because they are formed from two different monomers.

The polymerization of ethylene can lead to **branching,** which produces an amorphous polymer called low-density polyethylene (LDPE). High-density polyethylene (HDPE) and ultrahigh-molecular-weight polyethylene (UHMWPE) are not branched and are more crystalline, which makes them stronger. Nylon's properties are affected by hydrogen bonding between polymer strands.

Carbohydrates. The glucose unit is present in starch, glycogen, cellulose, sucrose, lactose, and simply as a **monosaccharide** in honey. It's the chief "sugar" in blood. As a monosaccharide, glucose is a pentahydroxyaldehyde in one form but it also exists in two cyclic forms. The latter are joined by oxygen bridges in the **disaccharides** and **polysaccharides.** In lactose (milk sugar), a glucose and a galactose unit are joined. In sucrose (table sugar), glucose and fructose units are linked.

The major polysaccharides—starch (amylose and amylopectin), glycogen, and cellulose—are all polymers of glucose but with different patterns and geometries of branching. The digestion of the disaccharides and starch requires the hydrolyses of the oxygen bridges to give monosaccharides.

Lipids. Natural products in living systems that are relatively soluble in nonpolar solvents, but not in water, are members of a large group of compounds called **lipids.** They include sex hormones and cholesterol, the triacylglycerols of nutritional importance, and the glycerophospholipids and other phospholipids needed for cell membranes.

The **triacylglycerols** are triesters between glycerol and three of a number of long-chain, often unsaturated **fatty acids.** In the digestion of the triacylglycerols, the hydrolysis of the ester groups occurs, and anions of fatty acids form (together with glycerol).

Molecules of glycerophospholipids have large segments that are hydrophobic and others that are hydrophilic. Glycerophospholipid molecules are the major components of cell membranes, where they are arranged in a lipid bilayer.

Amino Acids, Polypeptides, and Proteins. The **amino acids** in nature are mostly compounds with NH_3^+ and CO_2^- groups joined to the same carbon atom (called the alpha position of the amino acid). About 20 amino acids are important to the structures of polypeptides and proteins.

When two amino acids are linked by a **peptide bond** (an amide bond), the compound is a dipeptide. In **polypeptides,** several (sometimes thousands) of regularly spaced peptide bonds occur, involving as many amino acid units. The uniqueness of a polypeptide lies in its chain length and in the sequence of the side-chain groups.

Some **proteins** consist of only one polypeptide, but most proteins involve two or more (sometimes different) polypeptides and often a nonpolypeptide (an organic molecule) and a metal ion.

Nearly all **enzymes** are proteins. Major poisons and some drugs work by deactivating enzymes.

Nucleic Acids. The formation of a polypeptide with the correct amino acid sequence needed for a given protein is under the control of **nucleic acids.** Nucleic acids are polymers whose backbones are made of a repeating sequence of pentose sugar units. On each sugar unit is a **base**—a heterocyclic amine such as adenine (A), thymine (T), guanine (G), cytosine (C), or uracil (U). In **DNA,** the sugar is deoxyribose, and the bases are A, T, G, and C. In **RNA,** the sugar is ribose and the bases are A, U, G, and C.

DNA exists in cell nuclei as **double helices.** The two strands are associated side by side, with hydrogen bonds occurring between particular pairs of bases. In DNA, A is always paired to T; C is always paired to G. The base U replaces T in RNA, and A can also pair with U. The bases, A, U, G, and C, are the four letters of the genetic alphabet, and the specific combination that codes for one amino acid in polypeptide synthesis are three bases, side by side, on a strand. The **replication** of DNA is the synthesis by the cell of exact copies of the original two strands of a DNA double helix.

TOOLS

Tools for Problem Solving

The following tools related to organic chemicals and their reactions were introduced in this chapter.

Condensed structures (page 1049)

The key to writing condensed structures is keeping in mind the number of covalent bonds formed by the nonmetals in achieving an octet.

Group 4A	4 bonds	Group 5A	3 bonds	Group 6A	2 bonds
Group 7A	1 bond	hydrogen	1 bond		

In writing a condensed structure, be sure the number of hydrogens with a given element is sufficient to make up the difference between the number of non-hydrogen atoms attached and the total number of bonds required by the element in question.

Polygons as condensed structures (page 1051)

A carbon atom is understood at each corner; other elements in the ring are explicitly written. Edges of the polygon represent covalent bonds; double bonds are explicitly shown. The remaining bonds, as required by the covalence of the atom at a corner, are understood to hold H atoms.

Functional groups (page 1052)

If you can recognize a functional group in a molecule, you can place the structure into an organic family and so predict the kinds of reactions the compound can give. In particular, study Table 23.1.

IUPAC rules of nomenclature for organic compounds

For alkanes (page 1054) The longest continuous chain of carbon atoms defines the parent chain for which the alkane is named. The chain is numbered from whichever end gives the lowest number to the first substituent. The name ending is *-ane*, and the prefixes that describe the number of carbon atoms in the chain are given on page 1054. The locations of alkyl substituents are specified by a number and a hyphen preceding the name of the alkyl group. Alkyl groups are specified in alphabetical order.

Alkenes and alkynes (page 1058) The name ending for alkenes is *-ene*, and the name ending for alkynes is *-yne*. The rules are similar to those for naming alkanes, except that the chain is numbered so that the first carbon of the double or triple bond has the lower of two possible numbers.

Alcohols (page 1061) The name ending for alcohols is *-ol*. The parent chain is the longest chain that includes the alcohol group and is numbered from whichever end gives the lowest number to the —OH group.

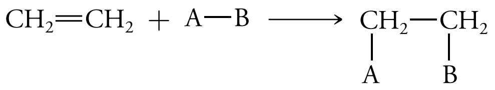
Aldehydes and ketones (page 1064) The name ending for aldehydes is *-al*. The parent chain is the longest chain that includes the aldehyde group. For ketones, the name ending is *-one*. The parent chain must include the carbonyl group and is numbered from whichever end gives the lowest number to the carbonyl carbon.

Carboxylic acids (page 1065) The name ending is *-oic acid*. The parent chain must include the carboxyl group.

Esters (page 1065) The name begins with the name of the alkyl group attached to the O atom. This is followed by a separate word taken from the name of the parent carboxylic acid, but altered by changing *-ic acid* to *-ate*.

Reactions of alkenes and alkynes (page 1059)

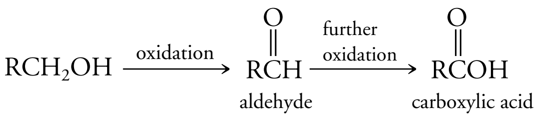
Components of a molecule add across a double bond.



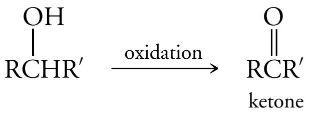
$$CH_2{=}CH_2 + A{-}B \longrightarrow \underset{A}{\underset{|}{CH_2}}{-}\underset{B}{\underset{|}{CH_2}}$$

Reactions of alcohols

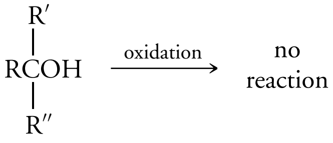
Oxidation of alcohols (page 1061) The product(s) depend on the number of hydrogens attached to the alcohol carbon.



$$RCH_2OH \xrightarrow{\text{oxidation}} \underset{\text{aldehyde}}{R\overset{\overset{O}{\|}}{C}H} \xrightarrow[\text{oxidation}]{\text{further}} \underset{\text{carboxylic acid}}{R\overset{\overset{O}{\|}}{C}OH}$$

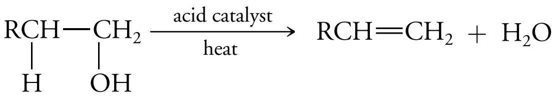


$$\overset{\displaystyle OH}{\overset{|}{RCHR'}} \xrightarrow{\text{oxidation}} \underset{\text{ketone}}{\overset{\displaystyle O}{\overset{\|}{RCR'}}}$$



$$\underset{\underset{\displaystyle R''}{|}}{\overset{\overset{\displaystyle R'}{|}}{RCOH}} \xrightarrow{\text{oxidation}} \text{no reaction}$$

Dehydration (page 1062)

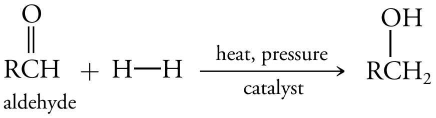


$$\underset{\underset{\displaystyle H}{|}}{RCH}-\underset{\underset{\displaystyle OH}{|}}{CH_2} \xrightarrow[\text{heat}]{\text{acid catalyst}} RCH{=}CH_2 + H_2O$$

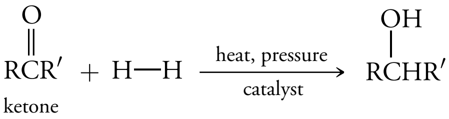
Substitution (page 1063)

$$ROH + HX(\text{conc.}) \xrightarrow{\text{heat}} RX + H_2O$$

Reactions of aldehydes and ketones: reduction (page 1064)



$$\underset{\text{aldehyde}}{\overset{\displaystyle O}{\overset{\|}{RCH}}} + H-H \xrightarrow[\text{catalyst}]{\text{heat, pressure}} \overset{\displaystyle OH}{\overset{|}{RCH_2}}$$



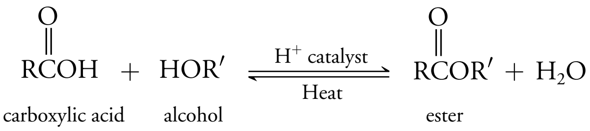
$$\underset{\text{ketone}}{\overset{\displaystyle O}{\overset{\|}{RCR'}}} + H-H \xrightarrow[\text{catalyst}]{\text{heat, pressure}} \overset{\displaystyle OH}{\overset{|}{RCHR'}}$$

Reactions of organic acids

Neutralization (page 1065) Carboxylic acids react with bases to give salts.

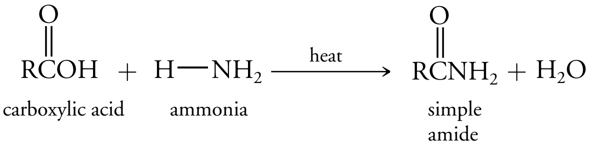
$$RCO_2H + OH^- \xrightarrow{H_2O} RCO_2^- + H_2O$$

Formation of esters (page 1066) Esters are formed in the reaction of a carboxylic acid with an alcohol.



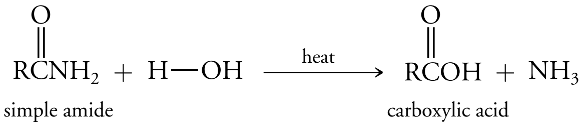
$$\underset{\text{carboxylic acid}}{\overset{\displaystyle O}{\overset{\|}{RCOH}}} + \underset{\text{alcohol}}{HOR'} \underset{\text{Heat}}{\overset{H^+ \text{ catalyst}}{\rightleftharpoons}} \underset{\text{ester}}{\overset{\displaystyle O}{\overset{\|}{RCOR'}}} + H_2O$$

Formation of amides (page 1069)



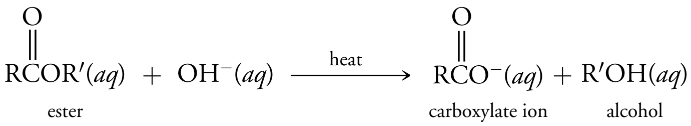
$$\underset{\text{carboxylic acid}}{\overset{\displaystyle O}{\overset{\|}{RCOH}}} + \underset{\text{ammonia}}{H-NH_2} \xrightarrow{\text{heat}} \underset{\text{simple amide}}{\overset{\displaystyle O}{\overset{\|}{RCNH_2}}} + H_2O$$

Hydrolysis of amides (page 1069)



$$\underset{\text{simple amide}}{\overset{\displaystyle O}{\overset{\|}{RCNH_2}}} + H-OH \xrightarrow{\text{heat}} \underset{\text{carboxylic acid}}{\overset{\displaystyle O}{\overset{\|}{RCOH}}} + NH_3$$

Saponification of esters (page 1066)



$$\underset{\text{ester}}{\mathrm{R\overset{\overset{\displaystyle O}{\|}}{C}OR'}(aq)} + \mathrm{OH^-}(aq) \xrightarrow{\text{heat}} \underset{\text{carboxylate ion}}{\mathrm{R\overset{\overset{\displaystyle O}{\|}}{C}O^-}(aq)} + \underset{\text{alcohol}}{\mathrm{R'OH}(aq)}$$

Addition polymerization (page 1072)

The addition of monomer units to a gradually growing chain by a free radical mechanism yields a long polymer chain. The repeating unit of the polymer has the formula of the monomer itself.

Condensation polymerization (page 1075)

Monomers are linked by the elimination of a small molecule such as H_2O or CH_3OH and the formation of a covalent bond between the remaining fragments. For copolymers, the repeating unit is that of the two monomers minus the small molecule that was eliminated.

= *WileyPLUS*, an online teaching and learning solution. *Note to instructors:* Many of the end-of-chapter problems are available for assignment via the *WileyPLUS* system. **www.wileyplus.com. ILW** = An Interactive Learningware solution is available for this problem. **OH** = An Office Hour video is available for this problem. Review Problems are presented in pairs separated by blue rules. Answers to problems whose numbers appear in blue are given in Appendix B. More challenging problems are marked with an asterisk *.

Review Questions

Structural Formulas

23.1 In general terms, what makes possible so many organic compounds?

23.2 What is the condensed structure of R if R—CH_3 represents the compound ethane?

23.3 Which of the following structures are possible, given the numbers of bonds that various atoms normally form?

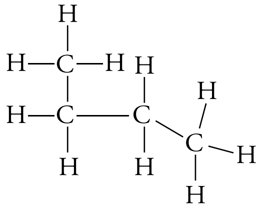
(a) $CH_2CH_2CH_3$

(b) $CH_3{=}CHCH_2CH_3$

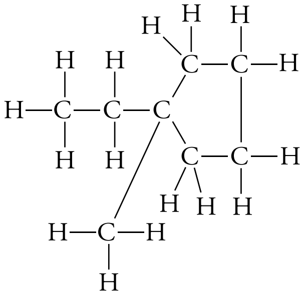
(c) $CH_3CH{=}CHCH_2CH_3$

23.4 Write condensed structures of the following:

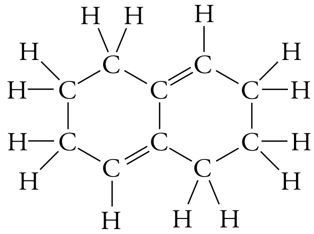
(a)



(b)



(c)

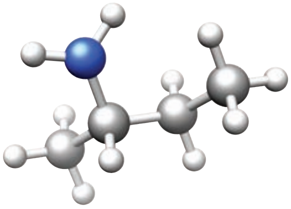


Families of Organic Compounds

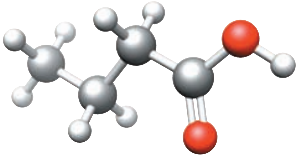
23.5 In $CH_3CH_2NH_2$, the NH_2 group is called the *functional* group. In *general terms*, why is it called this?

23.6 In general terms, why do functional groups impart more chemical reactivity to molecules that have them? Why don't the alkanes display as many reactions as, say, the amines?

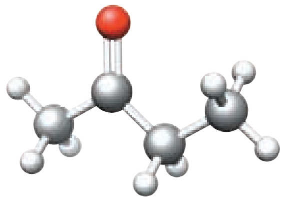
23.7 For each of the following, write the condensed structural formula and identify and name the functional group present in the molecule.



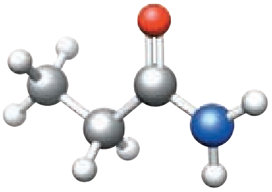
(a)



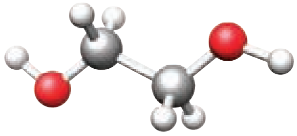
(b)



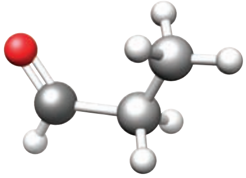
(c)



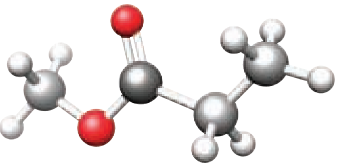
(d)



(e)



(f)



(g)

Isomers

23.8 What must be true about two substances if they are to be called isomers of each other?

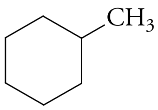
23.9 What prevents free rotation about a double bond and so makes geometric isomers possible?

Properties and Structure

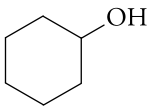
23.10 Explain why $CH_3CH_2CH_2OH$ is more soluble in water than $CH_3CH_2CH_2CH_3$.

23.11 Of the two compounds in Question 23.10, which has the higher boiling point? Explain.

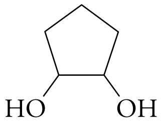
23.12 Examine the structures of the following compounds:



A



B

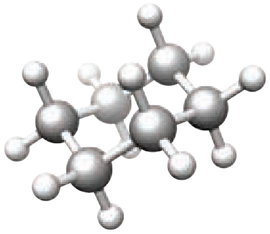


C

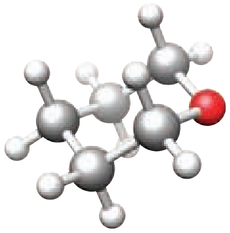
(a) Which has the highest boiling point? Explain.

(b) Which has the lowest boiling point? Explain.

23.13 Write condensed structures for the following. Which is more soluble in water? Explain.

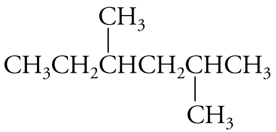


(a)



(b)

23.14 Which of the following compounds has the higher boiling point? Explain.



$$\underset{\textbf{A}}{CH_3CH_2\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_2\underset{\underset{\displaystyle CH_3}{|}}{C}HCH_3}$$

$CH_3CH_2CH_2CH_2CH_3$

B

23.15 Why do aldehydes and ketones have boiling points that are lower than those of their corresponding alcohols?

23.16 Acetic acid boils at 118 °C, higher even than 1-propanol, which boils at 97 °C. How can the higher boiling point of acetic acid be explained?

23.17 Methyl ethanoate has many more atoms than its parent acid, ethanoic acid. Yet methyl ethanoate (BP 59 °C) boils at a much lower temperature than ethanoic acid (BP 118 °C). How can this be explained?

23.18 Ethanamide is a solid at room temperature. 1-Aminobutane, which has about the same molecular mass, is a liquid. Explain.

23.19 Amines, RNH_2, do not have boiling points as high as alcohols with comparable numbers of atoms. Why?

Names

23.20 Write the condensed structures of the following compounds:

(a) 2,2-dimethyloctane

(b) 1,3-dimethylcyclopentane

(c) 1,1-diethylcyclohexane

(d) 6-ethyl-5-isopropyl-7-methyloct-1-ene

(e) *cis*-pent-2-ene

23.21 Write condensed structures of the following compounds:

(a) 3-methylbutanal

(b) 4-methyloctan-2-one

(c) 2-chloropropanoic acid

(d) 1-methylethyl ethanoate

(e) 2-methylbutanamide

23.22 Write condensed structures of the following compounds:

(a) butan-2,3-dione

(b) butanedicarboxylic acid

(c) 2-aminopropanal

(d) cyclohexyl 2-methylpropanoate

(e) sodium 2,3-dimethylbutanoate

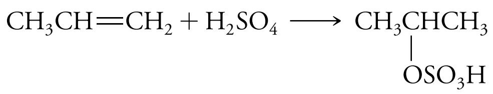
23.23 "3-Butanol" is not a proper name, but a structure could still be written for it. What is this structure, and what IUPAC name should be used?

23.24 No number is needed to identify the location of the double bond in $CH_3CH{=}CH_2$, propene. Why?

Chemical Properties of Organic Compounds

23.25 What are the products of the complete combustion of any hydrocarbon, assuming an abundant supply of oxygen?

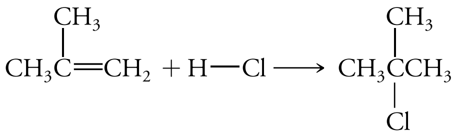
23.26 Propene is known to react with concentrated sulfuric acid as follows:



$$CH_3CH{=}CH_2 + H_2SO_4 \longrightarrow CH_3\underset{\displaystyle OSO_3H}{\underset{|}{C}}HCH_3$$

The reaction occurs in two steps. Write the equation for the first step.

23.27 2-Methylpropene reacts with hydrogen chloride as follows:



$$CH_3\overset{\displaystyle CH_3}{\overset{|}{C}}{=}CH_2 + H{-}Cl \longrightarrow CH_3\underset{\displaystyle Cl}{\underset{|}{\overset{\displaystyle CH_3}{\overset{|}{C}}}}CH_3$$

The reaction occurs in two steps. Write the equation of each step.

23.28 The compound but-2-ene exists as two isomers, but when both isomers are hydrogenated, the products are identical. Explain.

23.29 Briefly explain how the C—O bond in isopropyl alcohol is weakened when a strong acid is present.

23.30 Which isomer of butanol cannot be oxidized by dichromate ion? Write its structure and IUPAC name.

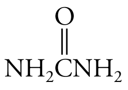
23.31 A monofunctional organic oxygen compound dissolves in aqueous base but not in aqueous acid. The compound is in which of the families of organic compounds that we studied? Explain.

23.32 A monofunctional organic nitrogen compound dissolves in aqueous hydrochloric acid but not in aqueous sodium hydroxide. What kind of organic compound is it?

23.33 Why are aqueous solutions of amides neutral while amines are basic?

***23.34** Hydrazine is a Brønsted base but urea does not exhibit basic properties. Offer an explanation.

NH_2NH_2
hydrazine



$$NH_2\overset{\displaystyle O}{\overset{\|}{C}}NH_2$$

urea

23.35 Write the equilibrium that is present when $CH_3CH_2CH_2NH_2$ is in an aqueous solution.

23.36 Predict which of the following species can neutralize the hydronium ion in dilute, aqueous HCl at room temperature.

(a) 
$$CH_3\overset{\displaystyle O}{\overset{\|}{C}}O^-$$

(c) HO^-

(e) $CH_3CH_2CH_2CH_3$

(b) CH_3NH_2

(d) 
$$CH_3\overset{\displaystyle O}{\overset{\|}{C}}NH_2$$

(f) 
23.37 Write the products that can be expected to form in the following situations. If no reaction occurs, write "no reaction."

(a) $CH_3CH_2CH_2NH_2 + HBr(aq) \longrightarrow$

(b) $CH_3CH_2CH_2CH_3 + HI(aq) \longrightarrow$

(c) $CH_3CH_2CH_2NH_3^+ + H_3O^+ \longrightarrow$

(d) $CH_3CH_2CH_2NH_3^+ + OH^- \longrightarrow$

23.38 Write the equation for the equilibrium that is present in a solution of propanoic acid and methanol with a trace of strong acid.

Polymers

23.39 What is a *macromolecule*? Name two naturally occurring macromolecular substances.

23.40 What is a *polymer*? Are all macromolecules polymers?

23.41 What is a *monomer*? Draw structures for the monomers used to make **(a)** polypropylene, **(b)** polytetrafluroethylene, and **(c)** polyvinyl chloride.

23.42 What do we mean by the term *polymer backbone*?

23.43 What is the repeating unit in polypropylene? Write the formula for the polypropylene polymer. Give three uses for polypropylene.

23.44 How do propylene and the repeating unit in polypropylene differ?

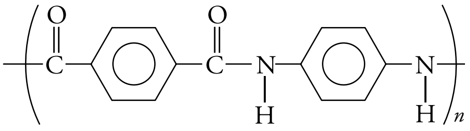
23.45 What is the difference between an *addition polymer* and *condensation polymer*?

23.46 Write the structure of polystyrene showing three of the repeating units. What are three uses for polystyrene plastic?

23.47 What is a *copolymer*?

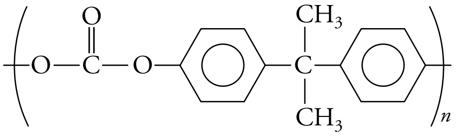
23.48 Write the structural formula for **(a)** nylon 6,6 and **(b)** poly(ethylene terephthalate).

23.49 The structural formula for Kevlar is



Identify the amide bond in this polymer.

23.50 Polycarbonate polymers are polyesters. An example is



Identify the structural feature that makes it a polyester. Identify the structural feature that makes it a poly*carbonate*.

23.51 What is meant by the term *branching* as applied to polymers? How does branching affect the properties of low-density polyethylene?

23.52 What is HDPE? Why does it form fibers easily?

23.53 What is UHMWPE? What range of molecular masses is found for this polymer?

23.54 How does polymer crystallinity affect the physical properties of the polymer?

23.55 Why doesn't low-density polyethylene form strong crystalline polymer fibers?

23.56 Why does nylon form strong fibers?

23.57 Show how hydrogen bonding can bind Kevlar polymer chains together. (See Question 23.49.)

23.58 What are some applications of crystalline polymers such as HDPE, UHMWPE, and Kevlar?

Biochemistry

23.59 What is biochemistry?

23.60 What are the three fundamental needs for sustaining life, and what are the general names for the substances that supply these needs?

Carbohydrates

23.61 How are carbohydrates defined?

23.62 What monosaccharide forms when the following polysaccharides are completely hydrolyzed? **(a)** starch, **(b)** glycogen, **(c)** cellulose

23.63 Glucose exists in three forms, only one of which is a polyhydroxyaldehyde. How, then, can an aqueous solution of any form of glucose undergo the reactions of an aldehyde?

23.64 Name the compounds that form when sucrose is digested.

23.65 The digestion of lactose gives what compounds? Name them.

23.66 The complete hydrolysis of the following compounds gives what product(s)? (Give the names only.)

(a) amylose **(b)** amylopectin

23.67 Describe the relationships among amylose, amylopectin, and starch.

23.68 Why are humans unable to use cellulose as a source of glucose?

23.69 What function is served by glycogen in the body?

Lipids

23.70 How are lipids defined?

23.71 Why are lipids more soluble than carbohydrates in nonpolar solvents?

23.72 Cholesterol is not an ester, yet it is defined as a lipid. Why?

23.73 A product such as corn oil is advertised as "polyunsaturated," but all nutritionally important lipids have unsaturated $C{=}O$ groups. What does "polyunsaturated" refer to?

23.74 Is it likely that the following compound could be obtained by the hydrolysis of a naturally occurring lipid? Explain.

$$CH_3(CH_2)_2CH{=}CHCH_2CH{=}CHCH_2CH{=}CH(CH_2)_7CO_2H$$

Amino Acids, Polypeptides, and Proteins

23.75 Describe the specific ways in which the monomers for all polypeptides are **(a)** alike and **(b)** different.

23.76 What is the peptide bond? How is it similar to the amide bond in nylon?

23.77 Describe the structural way in which two *isomeric* polypeptides would be different.

23.78 Describe the structural ways in which two different polypeptides can differ.

23.79 Why is a distinction made between the terms *polypeptide* and *protein*?

23.80 In general terms, what forces are at work that determine the final *shape* of a polypeptide strand?

23.81 What kind of substance makes up most enzymes?

23.82 The most lethal chemical poisons act on what kinds of substances? Give examples.

Nucleic Acids and Heredity

23.83 In general terms only, how does the body solve the problem of getting a particular amino acid sequence, rather than a mixture of randomly organized sequences, into a polypeptide?

23.84 In what specific structural way does DNA carry genetic messages?

23.85 What kind of force occurs between the two DNA strands in a double helix?

23.86 How are the two DNA strands in a double helix structurally related?

23.87 In what ways do DNA and RNA differ structurally?

23.88 Which base pairs with **(a)** A in DNA, **(b)** A in RNA, and **(c)** C in DNA or RNA?

23.89 The process of *transcription* begins with which nucleic acid and ends with which one?

23.90 The process of *translation* begins with which nucleic acid? What is the end result of translation?

Review Problems

Structural Formulas

23.91 Write full (expanded) structures for each of the following molecular formulas. Remember how many bonds the various kinds of atoms must have. In some you will have to use double or triple bonds. (*Hint:* A trial-and-error approach will have to be used.)

(a) CH_5N **(c)** $CHCl_3$ **(e)** C_2H_2

(b) CH_2Br_2 **(d)** NH_3O **(f)** N_2H_4

23.92 Write full (expanded) structures for each of the following molecular formulas. Follow the guidelines of Problem 23.91.

(a) C_2H_6 **(c)** CH_2O **(e)** C_3H_3N

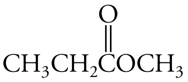
(b) CH_2O_2 **(d)** HCN **(f)** CH_4O

Families of Organic Compounds

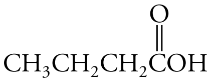
23.93 Name the family to which each compound belongs.

(a) $CH_3CH{=}CH_2$

(b) CH_3CH_2OH

(c)


$CH_3CH_2\overset{O}{\overset{\|}{C}}OCH_3$

(d)


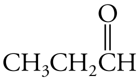
$CH_3CH_2CH_2\overset{O}{\overset{\|}{C}}OH$

(e) $CH_3CH_2CH_2NH_2$

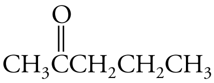
(f) $HOCH_2CH_2CH_3$

23.94 To what organic family does each compound belong?

(a) $CH_3C{\equiv}CH$

(b)


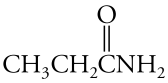
$CH_3CH_2\overset{O}{\overset{\|}{C}}H$

(c)


$CH_3\overset{O}{\overset{\|}{C}}CH_2CH_2CH_3$

(d) $CH_3{-}O{-}CH_2CH_3$

(e) $CH_3CH_2NH_2$

(f)


$CH_3CH_2\overset{O}{\overset{\|}{C}}NH_2$

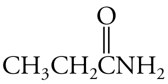
23.95 Identify by letter the compounds in Problem 23.93 that are saturated compounds.

23.96 Which parts of Problem 23.94 give the structures of saturated compounds?

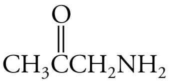
23.97 Classify the following compounds as amines or amides. If another functional group occurs, name it too.

(a) $CH_3CH_2NH_2$

(b) $CH_3CH_2NHCH_3$

(c)


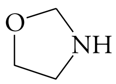
$CH_3CH_2\overset{O}{\overset{\|}{C}}NH_2$

(d)


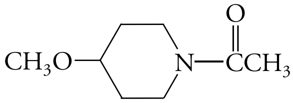
$CH_3\overset{O}{\overset{\|}{C}}CH_2NH_2$

23.98 Name the functional groups present in each of the following structures:

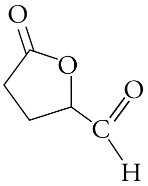
(a)

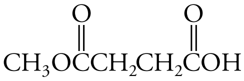


(b)



(c)

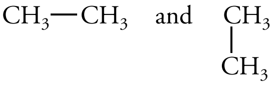


(d)


$CH_3O\overset{O}{\overset{\|}{C}}CH_2CH_2\overset{O}{\overset{\|}{C}}OH$

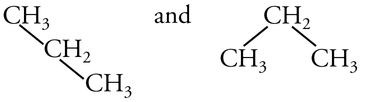
Isomers

23.99 Decide whether the members of each pair are identical, are isomers, or are unrelated.

(a)


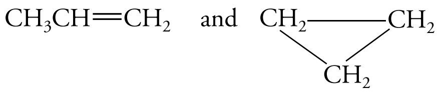
$CH_3{-}CH_3$ and $\begin{matrix}CH_3\\|\\CH_3\end{matrix}$

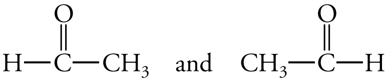
(b)



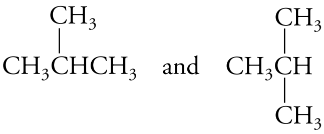
(c) CH_3CH_2OH and $CH_3CH_2CH_2OH$

(d)



(e)


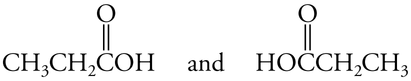
$H{-}\overset{O}{\overset{\|}{C}}{-}CH_3$ and $CH_3{-}\overset{O}{\overset{\|}{C}}{-}H$

(f)


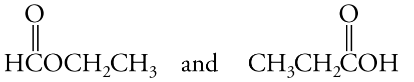
$CH_3\overset{CH_3}{\overset{|}{C}}HCH_3$ and $CH_3\underset{CH_3}{\underset{|}{\overset{CH_3}{\overset{|}{C}}}}H$

(g) $CH_3CH_2CH_2NH_2$ and $CH_3CH_2{-}NH{-}CH_3$

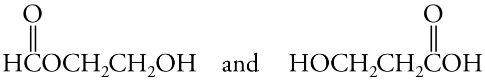
23.100 Examine each pair and decide if the two are identical, are isomers, or are unrelated.

(a)


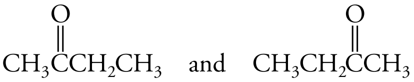
$CH_3CH_2\overset{O}{\overset{\|}{C}}OH$ and $HO\overset{O}{\overset{\|}{C}}CH_2CH_3$

(b)


$H\overset{O}{\overset{\|}{C}}OCH_2CH_3$ and $CH_3CH_2\overset{O}{\overset{\|}{C}}OH$

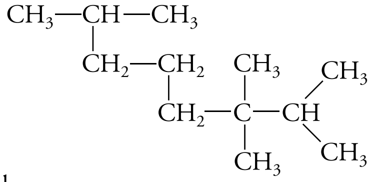
(c)


$H\overset{O}{\overset{\|}{C}}OCH_2CH_2OH$ and $HOCH_2CH_2\overset{O}{\overset{\|}{C}}OH$

(d)


$CH_3\overset{O}{\overset{\|}{C}}CH_2CH_3$ and $CH_3CH_2\overset{O}{\overset{\|}{C}}CH_3$

(e)



and

(f) $CH_3{-}NH{-}\overset{\overset{O}{\|}}{C}{-}CH_3$ and $CH_3CH_3\overset{\overset{O}{\|}}{C}NH_2$

(g) $H{-}O{-}O{-}H$ and $H{-}O{-}H$

Names of Hydrocarbons

23.101 Write the IUPAC names of the following hydrocarbons:

(a) $CH_3CH_2CH_2CH_2CH_3$

(b) $CH_3CH_2CH_2\underset{\underset{CH_3}{|}}{C}HCH_3$

(c) $CH_3\overset{\overset{CH_3}{|}}{C}HCH_2\underset{\underset{CH_3}{|}}{C}HCH_2CH_3$

23.102 Write the IUPAC names of the following compounds:

(a) $CH_3CH_2\overset{\overset{CH_3}{|}}{C}HCH_2\underset{\underset{CH_3}{|}}{C}HCH_3$

(b) $CH_3CH_2CH{=}CHCH_2CH_3$

(c) $CH_3\overset{\overset{CH_3}{|}}{C}HCH{=}CHCH_3$

Geometric Isomerism

23.103 Write the structures of the cis and trans isomers, *if any,* for the following:

(a) $CH_2{=}CHBr$

(b) $CH_3CH{=}CHCH_2CH_3$

(c) $CH_3\overset{\overset{Br}{|}}{C}{=}CHCl$

23.104 Write the structures of the cis and trans isomers, if any, for the following compounds:

(a) $CH_3\overset{\overset{CH_3}{|}}{C}{=}CHCH_3$

(b) $CH_3CH{=}\overset{\overset{CH_3}{|}}{C}CH_2CH_3$

(c) $CH_3CH_2\overset{\overset{Cl}{|}}{C}{=}\overset{\overset{Cl}{|}}{C}CH_2CH_3$

Chemical Reactions of Alkenes

23.105 Write the structures of the products that form when ethylene reacts with each of the following substances by an addition reaction. (Assume that needed catalysts or other conditions are provided.)

(a) H_2
(b) Cl_2
(c) Br_2
(d) $HCl(g)$
(e) $HBr(g)$
(f) H_2O (in acid)

23.106 The isopropyl cation is more stable than the propyl cation, so the former forms almost exclusively when propene undergoes addition reactions with proton-donating species. On the basis of this fact, predict the final products of the reaction of propene with each of the following reagents:

(a) hydrogen chloride

(b) hydrogen iodide

(c) water in the presence of an acid catalyst

23.107 Repeat Problem 23.105 using but-2-ene.

23.108 Repeat Problem 23.106 using cyclohexene.

23.109 In general terms, why doesn't benzene undergo the same kinds of addition reactions as cyclohexene?

23.110 If one mole of benzene were to *add* one mole of Br_2, what would form? What forms, instead, when Br_2, benzene, and an $FeBr_3$ catalyst are heated together? (Write the structures.)

Structures and Properties of Other Functional Groups

23.111 Write condensed structures and the IUPAC names for all of the saturated alcohols with three or fewer carbon atoms per molecule.

23.112 Write the condensed structures and the IUPAC names for all of the possible alcohols with the general formula $C_4H_{10}O$.

23.113 Write the condensed structures of all of the possible ethers with the general formula $C_4H_{10}O$. Following the pattern for the common names of ethers given in the chapter, what are the likely common names of these ethers?

23.114 Write the structures of the isomeric alcohols of the formula $C_4H_{10}O$ that could be oxidized to aldehydes. Write the structure of the isomer that could be oxidized to a ketone.

*__23.115__ Write the structures of the products of the acid-catalyzed dehydrations of the following compounds:

(a) 
(b) 
(c) 
23.116 Write the structures of the substitution products that form when the alcohols of Problem 23.115 are heated with concentrated hydroiodic acid.

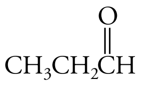
23.117 Write the structures of the aldehydes or ketones that can be prepared by the oxidation of the compounds given in Problem 23.115.

23.118 Write the structure of the product of the acid-catalyzed dehydration of propan-2-ol. Write the mechanism of the reaction.

23.119 When ethanol is heated in the presence of an acid catalyst, ethene and water form; an elimination reaction occurs. When butan-2-ol is heated under similar conditions, *two* alkenes form (although not in equal quantities). Write the structures and IUPAC names of these two alkenes.

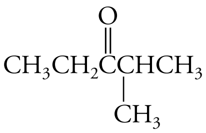
23.120 If the formation of the two alkenes in Problem 23.119 were determined purely by statistics, then the mole ratio of the two alkenes should be in the ratio of what whole numbers? Why?

23.121 Which of the following two compounds could be easily oxidized? Write the structure of the product of the oxidation.



$CH_3CH_2\overset{\overset{O}{\|}}{C}H$

A



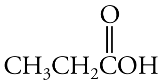
$CH_3CH_2\overset{\overset{O}{\|}}{C}\underset{\underset{CH_3}{|}}{C}HCH_3$

B

23.122 Which of the following compounds has the chemical property given below? Write the structure of the product of the reaction.

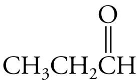
$CH_3CH_2CH_2OH$

A



$CH_3CH_2\overset{\overset{O}{\|}}{C}OH$

B



$CH_3CH_2\overset{\overset{O}{\|}}{C}H$

C

(a) Is easily oxidized

(b) Neutralizes NaOH

(c) Forms an ester with methyl alcohol

(d) Can be oxidized to an aldehyde

(e) Can be dehydrated to an alkene

23.123 Write the structures of the products that form in each of the following situations. If no reaction occurs, write "no reaction."

(a) $CH_3CH_2CO_2^- + HCl(aq) \longrightarrow$

(b) $CH_3CH_2CO_2CH_3 + H_2O \xrightarrow{\text{heat}}$

(c) $CH_3CH_2CH_2CO_2H + NaOH(aq) \longrightarrow$

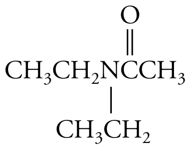
23.124 Write the structures of the products that form in each of the following situations. If no reaction occurs, write "no reaction."

(a) $CH_3CH_2CO_2H + NH_3 \xrightarrow{\text{heat}}$

(b) $CH_3CH_2CH_2CONH_2 + H_2O \xrightarrow{\text{heat}}$

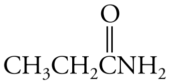
(c) $CH_3CH_2CO_2CH_3 + NaOH(aq) \xrightarrow{\text{heat}}$

*__23.125__ What organic products with smaller molecules form when the following compound is heated with water?



$CH_3CH_2\underset{\underset{CH_3CH_2}{|}}{N}\overset{\overset{O}{\|}}{C}CH_3$

23.126 Which of the following species undergo the reaction specified? Write the structures of the products that form.



$CH_3CH_2\overset{\overset{O}{\|}}{C}NH_2$ $CH_3CH_2CH_2NH_2$ $CH_3CH_2NH_3^+$

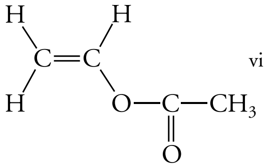
(a) Neutralizes dilute hydrochloric acid

(b) Hydrolysis

(c) Neutralizes dilute sodium hydroxide

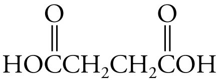
Polymers

23.127 The structure of vinyl acetate is shown below. This compound forms a chain-growth polymer in the same way as ethylene and propylene. Draw a segment of the poly(vinyl acetate) polymer that contains three of the repeating units.



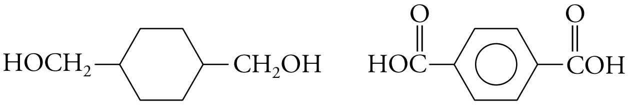
vinyl acetate

23.128 If the following two compounds polymerized in the same way that Dacron forms, what would be the repeating unit of their polymer?



$HO\overset{\overset{O}{\|}}{C}CH_2CH_2\overset{\overset{O}{\|}}{C}OH$ $HOCH_2CH_2OH$

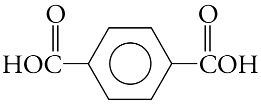
23.129 Kodel, a polyester made from the following monomers, is used to make fibers for weaving crease-resistant fabrics.



monomers for Kodel

What is the structure of the repeating unit in Kodel?

23.130 If the following two compounds polymerized in the same way that nylon forms, what would be the repeating unit in the polymer?

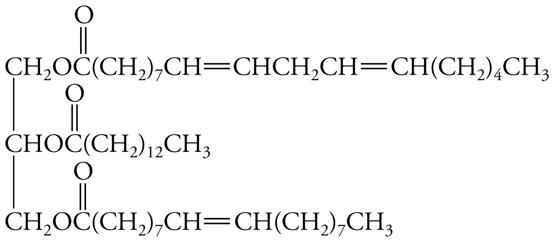


$NH_2CH_2CH_2CH_2CH_2NH_2$

Lipids

23.131 Write the structure of a triacylglycerol that could be made from palmitic acid, oleic acid, and linoleic acid.

23.132 Write the structures of the products of the complete hydrolysis of the following triacylglycerol:



$$\begin{array}{l} \mathrm{CH_2O\overset{O}{\overset{\|}{C}}(CH_2)_7CH{=}CHCH_2CH{=}CH(CH_2)_4CH_3} \\ | \\ \mathrm{CHO\overset{O}{\overset{\|}{C}}(CH_2)_{12}CH_3} \\ | \\ \mathrm{CH_2O\overset{O}{\overset{\|}{C}}(CH_2)_7CH{=}CH(CH_2)_7CH_3} \end{array}$$

23.133 Write the structure of the triacylglycerol that would result from the complete hydrogenation of the lipid whose structure is given in Problem 23.132.

23.134 If the compound in Problem 23.132 is saponified, what are the products? Give their names and structures.

23.135 What parts of glycerophospholipid molecules provide hydrophobic sites? Which provide hydrophilic sites?

23.136 In general terms, describe the structure of the membrane of an animal cell. What kinds of molecules are present? How are they arranged? What forces keep the membrane intact? What functions are served by the protein components?

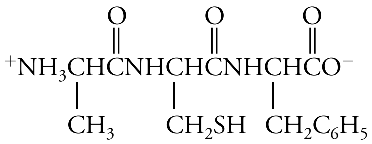
Amino Acids and Polypeptides

23.137 Write the structure of the dipeptide that could be hydrolyzed to give two molecules of glycine.

23.138 What is the structure of the tripeptide that could be hydrolyzed to give three molecules of alanine?

23.139 What are the structures of the two dipeptides that could be hydrolyzed to give glycine and phenylalanine?

23.140 Write the structures of the dipolar ionic forms of the amino acids that are produced by the complete digestion of the following compound:

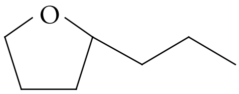


$$\mathrm{{}^{+}NH_3\underset{CH_3}{\underset{|}{CH}}\overset{O}{\overset{\|}{C}}NH\underset{CH_2SH}{\underset{|}{CH}}\overset{O}{\overset{\|}{C}}NH\underset{CH_2C_6H_5}{\underset{|}{CH}}\overset{O}{\overset{\|}{C}}O^-}$$

Additional Exercises

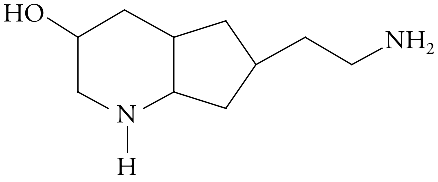
23.141 Write molecular formulas for the following:

(a)



(b)

(c)



***23.142** The H_2SO_4-catalyzed addition of water to 2-methylpropene could give two isomeric alcohols.

(a) Write their condensed structures.

(b) Actually, only one forms. It is not possible to oxidize this alcohol to an aldehyde or to a ketone having four carbons. Which alcohol, therefore, is the product?

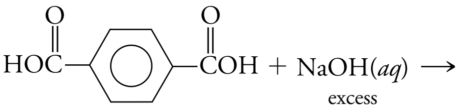
(c) Write the structures of the two possible carbocations that could form when sulfuric acid donates a proton to 2-methylpropene.

(d) One of the two carbocations of part (c) is more stable than the other. Which one is it, and how can you tell?

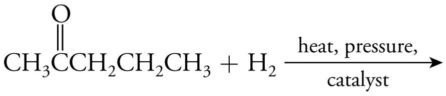
23.143 Suggest a reason why trimethylamine, $(CH_3)_3N$, has a *lower* boiling point (BP 3 °C) than dimethylamine, $(CH_3)_2NH$ (BP 8 °C), despite having a larger number of atoms.

23.144 Write the structures of the organic products that form in each situation. If no reaction occurs, write "no reaction."

(a)



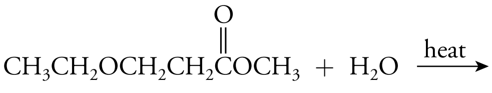
(b)



$$\mathrm{CH_3\overset{O}{\overset{\|}{C}}CH_2CH_2CH_3 + H_2 \xrightarrow[\text{catalyst}]{\text{heat, pressure,}}}$$

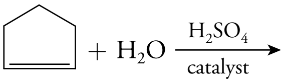
(c) $\mathrm{CH_3\overset{+}{N}H_2CH_2CH_2CH_3} + \mathrm{OH^-}(aq) \longrightarrow$

(d)

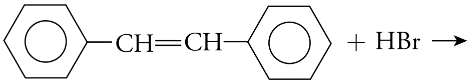


$$\mathrm{CH_3CH_2OCH_2CH_2\overset{O}{\overset{\|}{C}}OCH_3 + H_2O \xrightarrow{\text{heat}}}$$

(e)



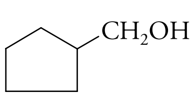
(f)



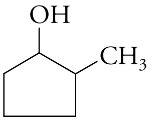
***23.145** How many tripeptides can be made from three different amino acids? If the three are glycine (Gly), alanine (Ala), and phenylalanine (Phe), what are the structures of the possible tripeptides. (*Hint:* Gly-Ala-Phe is one structure.)

Multi-Concept Problems

23.146 An unknown alcohol was either **A** or **B** below. When the unknown was oxidized with an *excess* of strong oxidizing agent, sodium dichromate in acid, the *organic* product isolated was able to neutralize sodium hydroxide.



A



B

(a) Which was the alcohol? Give the reasons for this choice.

(b) What is the molecular formula of the product of the oxidation?

(c) Draw the structural formula of the product.

(d) What is the minimum number of grams of sodium dichromate needed to oxidize 36.8 g of the alcohol?

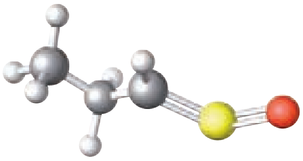
(e) If 36.8 g of the alcohol was oxidized and all of the product was collected, how many grams of NaOH could it neutralize?

23.147 Estimate the number of kilojoules of heat that would be liberated in the complete combustion of 11.35 g of gaseous compound B in the preceding problem. (*Hint:* Use bond energy data to estimate the standard heat of formation of the compound.)

23.148 A 6.225 mg sample of a monoprotic organic acid, when burned in pure oxygen, gave 12.44 mg of CO_2 and 5.091 mg H_2O. What are the empirical and molecular formulas for this acid? How many milliliters of 0.224 *M* KOH are needed to react completely with 0.822 g of the acid? Draw the structure of the ester that this acid would form with ethanol.

23.149 When 0.2081 g of an organic acid was dissolved in 50.00 mL of 0.1016 *M* NaOH, it took 23.78 mL of 0.1182 *M* HCl to neutralize the NaOH that was not used up by the sample of the organic acid. Calculate the formula mass from the data given. Is the answer necessarily the *molecular mass* of the organic acid? Explain.

23.150 The compound that causes your eyes to water when you chop an onion has the following molecular structure:



How many grams of oxygen would be required for the complete combustion of 1.225 g of this compound?

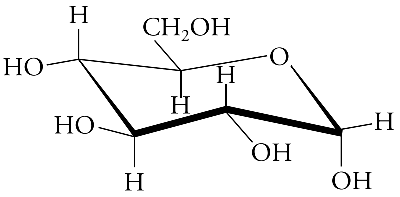
Exercises in Critical Thinking

23.151 The compound CH_2Cl_2 only exists as one isomer. Why does this support the statement that the H and Cl atoms in the compound are arranged tetrahedrally around the carbon rather than in a square planar structure?

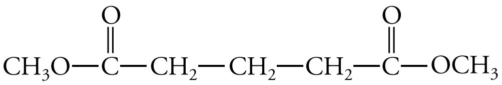
23.152 The α-carbon atom in an amino acid is a chiral center (except for glycine). Of the two possible enantiomers of these optically active substances, only one is produced naturally. What does this suggest about the mechanism whereby amino acids are synthesized in living creatures?

23.153 Use resonance structures to explain why urea, $(NH_2)_2C{=}O$, is not basic like typical amines. Without using resonance structures, use electronegativities to explain the same fact.

23.154 Below is the ring structure of a sugar molecule. How many chiral centers does this sugar molecule have? How many isomers are possible?



23.155 What would be the repeating unit of the polymer formed by condensation polymerization of the two monomers shown below?



$$CH_3O-\overset{\overset{\large O}{\|}}{C}-CH_2-CH_2-CH_2-\overset{\overset{\large O}{\|}}{C}-OCH_3$$

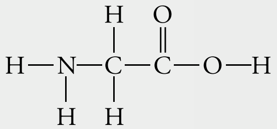
$$H_2N-CH_2-CH_2-NH_2$$

Chapters 21–23

Bringing It Together

Again we pause to provide you with an opportunity to see how well you have grasped concepts, how familiar you are with important terms, and how able you are at working chemistry problems. Keep in mind that many of the problems require tools developed in more than one chapter, including tools from Chapters 1–20. As you proceed, we encourage you to follow the approach taken by the worked examples you've studied.

1. Glycine, one of the important amino acids, has the structure



$$\mathrm{H{-}\underset{H}{N}{-}\overset{H}{\underset{H}{C}}{-}\overset{O}{\overset{\|}{C}}{-}O{-}H}$$

Calculate the atomization energy of this molecule from the data in Table 19.4.

2. Suppose that the total mass of the reactants in a chemical reaction is 100.00000 g. How many kilojoules of energy would have to evolve from this reaction if the total mass of the products will be 99.99900 g? If all this energy were used to heat water, how many liters of water could have its temperature raised from 10 °C to 100 °C?

3. Even though thorium does not undergo fission, it has been proposed as a fuel for nuclear reactors because it is abundant, can be easily converted to ^{233}U (an isotope that does undergo fission) by bombardment with low-energy neutrons, and because the production of nuclear weapons by this route is extremely difficult and hazardous. Formation of ^{233}U begins with the absorption of neutron by ^{232}Th. The product of that reaction then decays to ^{233}Pa, which then decays to ^{233}U. Write nuclear equations for the nuclear reactions described above. If fission of ^{233}U releases 197.9 MeV per atom, how many joules are released by fission of 100 g of ^{233}U?

4. How many gallons of octane, C_8H_{18}, having a density of $0.703\ \mathrm{g\ cm^{-3}}$, would have to be burned to produce the same amount of energy as in the following production of 3.15 g of ^4_2He by the fusion reaction

$$^2_1H + {}^2_1H \longrightarrow {}^4_2He$$

Accurate atomic masses: $^2_1H = 2.014102$ u, $^4_2He = 4.002603$ u. For $C_8H_{18}(l)$, $\Delta H^\circ_f = 208.4\ \mathrm{kJ\ mol^{-1}}$.

5. Radium-226 (atomic mass = 226.03), the only naturally occurring isotope of this element, follows the decay sequence shown below.

$$^{226}Ra \xrightarrow[1602\ \text{year}]{\alpha} {}^{222}Rn \xrightarrow[3.82\ \text{day}]{\alpha} {}^{218}Po \xrightarrow[3.10\ \text{min}]{\alpha} {}^{214}Pb$$

Each step occurs by alpha emission. The half-life for each step is shown below the arrow. How many years would it take for a 1.56 g sample of ^{226}Ra to produce 13.34 mL of helium measured at 27 °C and 674 torr following this decay sequence?

6. The reaction

$$Ni(H_2O)_6{}^{2+} + 6NH_3 \longrightarrow Ni(NH_3)_6{}^{2+} + 6H_2O$$

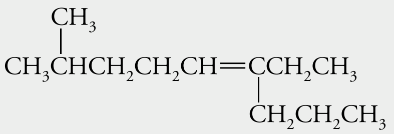
can be described as the displacement of one Lewis base by another. Explain. What is the Lewis acid in the reaction?

7. Sketch the chiral isomers of $[Cr(H_2O)_2(en)_2]^{3+}$. Is there a nonchiral isomer of this complex? What is the name of $[Cr(H_2O)_2(en)_2]Cl_3$?

8. When an aqueous solution of potassium tris(oxalato)cobaltate(III) is boiled, a redox reaction occurs in which some of the oxalate is oxidized to CO_2 and the cobalt(III) is reduced to cobalt(II), thereby destroying the complex. Suppose 0.556 g of the potassium tris(oxalato)cobaltate(III) is dissolved in water, boiled, and then the remaining oxalate is titrated in an acidic solution with 0.015 *M* $KMnO_4$ solution. During the titration, oxalate (actually present as oxalic acid in the acidified solution) is oxidized to CO_2 and the permanganate ion is reduced to manganese(II) ion. How many milliliters of the $KMnO_4$ solution will be required in the titration?

9. Which complex would absorb light of a shorter wavelength, $[V(H_2O)_6]^{3+}$ or $[V(CN)_6]^{3-}$? Justify your answer.

10. Name the following organic compound.



$$\mathrm{CH_3\overset{CH_3}{C}HCH_2CH_2CH{=}\underset{CH_2CH_2CH_3}{C}CH_2CH_3}$$

11. How many milliliters of H_2 measured at 766 torr and 25.6 °C are needed to hydrogenate the double bond in 12.4 g of the compound in the preceding question?

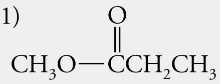
12. Draw the structure of 4-ethyl-2,2-dimethylheptan-3-ol. What is the name of the product that will form if this compound is oxidized with potassium dichromate in an acidic solution? Write a balanced equation for the combustion of this oxidation product in an excess supply of oxygen.

13. How many grams of $K_2Cr_2O_7$ are needed to oxidize 34.9 g of 4-ethyl-2,2-dimethylheptan-3-ol as described in the preceding problem?

14. Proteins bind to metal ions using various amino acids. One such amino acid is cysteine, which has an S^- at the end of a carbon chain. Typically, four cysteine units use their sulfides to bind tightly to Zn(II) ions. The equilibrium dissociation constant for binding of Zn(II) at pH 7.0 is 8.0×10^{-12}. If the ΔH for the reaction is 26.8 kJ/mol, what is the value for ΔS for the reaction? What does this value for ΔS indicate about the entropy change for the reaction?

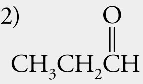
15. Which of the following compounds (a) neutralizes NaOH, (b) neutralizes HCl, (c) yields an alcohol and an organic acid when hydrolyzed, (d) is easily oxidized to an acid, (e) would be classified as aromatic, (f) would be oxidized to give a ketone?

(1)



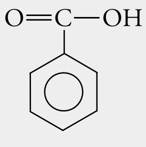
$CH_3O-\overset{\displaystyle O}{\overset{\|}{C}}CH_2CH_3$

(2)

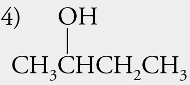


$CH_3CH_2\overset{\displaystyle O}{\overset{\|}{C}}H$

(3)

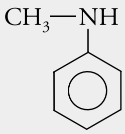


(4)

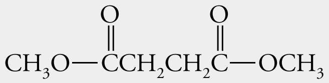


$CH_3\underset{}{\overset{\displaystyle OH}{\overset{|}{C}}}HCH_2CH_3$

(5)



16. What would be the repeating structural unit if a condensation polymer were to form from the following monomers by the elimination of CH_3OH?

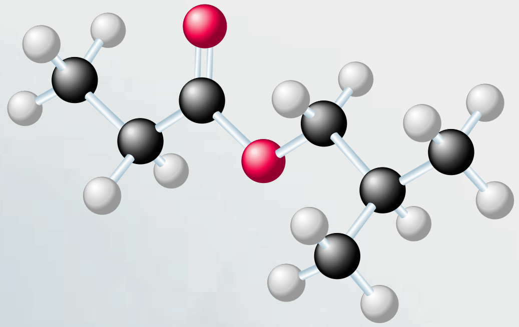


$CH_3O-\overset{\displaystyle O}{\overset{\|}{C}}CH_2CH_2\overset{\displaystyle O}{\overset{\|}{C}}-OCH_3$

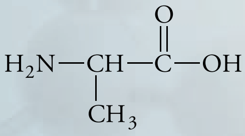
$H_2NCH_2CH_2CH_2NH_2$

17. How do the water solubilities compare for monosaccharides and lipids? On the basis of their molecular structures, why do these differences exist?

18. What are the names of the acid and alcohol from which the following ester is formed?

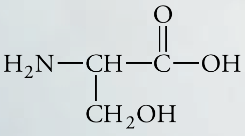


19. Write the structures of all of the tripeptides that could be made from the following if each tripeptide includes all three amino acids. If these amino acids could occur more than once, what is the total number of tripeptides they could form?



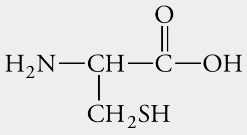
$H_2N-\underset{\displaystyle CH_3}{\underset{|}{CH}}-\overset{\displaystyle O}{\overset{\|}{C}}-OH$

Alanine
(Ala)



$H_2N-\underset{\displaystyle CH_2OH}{\underset{|}{CH}}-\overset{\displaystyle O}{\overset{\|}{C}}-OH$

Serine
(Ser)



$H_2N-\underset{\displaystyle CH_2SH}{\underset{|}{CH}}-\overset{\displaystyle O}{\overset{\|}{C}}-OH$

Cysteine
(Cys)

20. Sketch the structure of the $[FeF_6]^{4-}$ ion. How many unpaired electrons is it likely to have? Draw an energy level diagram showing the populations of the *d*-orbital energy levels in the complex. Write the mass action expression that corresponds to K_{form} for the complex.

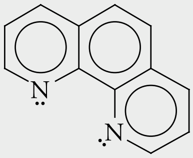
21. Deuterium, ^2_1H, can be incorporated into molecules in place of the common isotope, ^1_1H. Doing so can influence the rate of reaction. Would reaction rates be increased or decreased? Why?

22. An organic compound was analyzed and found to contain 34.626% carbon and 3.874% hydrogen, the remainder being oxygen. A solution of the compound in water tested acidic, and when 0.463 g of the compound was dissolved in water, it required 26.56 mL of 0.3350 *M* NaOH for complete neutralization in a titration. What is the likely structural formula of the compound?

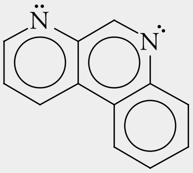
23. Strontium-90, a beta emitter, has a half-life of 28.1 yr. If 36.2 mg of ^{90}Sr were incorporated in the bones of a growing child, how many beta particles would the child absorb from this source in 1.00 day?

24. When uranium-238 is bombarded by a particular bombarding particle, it can be transmuted into plutonium-239 and neutrons. Which bombarding particle accomplishes this? How many neutrons are produced for each plutonium-239 atom? Write the nuclear equation for this change.

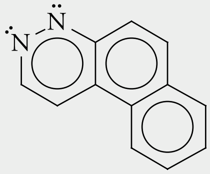
25. Which of the compounds below would most likely behave as a bidentate ligand? Explain your choice and why you eliminated the other two.



(a)



(b)



(c)

Appendix A

Review of Mathematics

The purpose of this Appendix is to provide a brief review of math topics you will use in solving various chemistry problems in this book. We recommend that you refer to the topics discussed here when you find you are having difficulty in following the math in worked examples, when you are unsure as to how to proceed with solving the math in an exercise or homework problem, or when answers you obtain do not match those in Appendix B.

A.1 | Exponential and Scientific Notation

Very large and very small numbers are generally expressed as powers of ten. This is often called **exponential notation.** When the quantity is expressed as *a number between 1 and 10* multiplied by 10 raised to a power (e.g., 3.2×10^5), we also call it **standard scientific notation** (or simply **scientific notation**). Some examples are given in Table A.1. If you have a scientific calculator, it is able to express numbers in scientific notation and it permits you to perform arithmetic on numbers expressed this way. Some tips on using scientific calculators are described later in Appendix A.5.

Even though you have a calculator at your disposal, it is important that you understand how to write these numbers and how to perform arithmetic with them. Such an ability provides a way to quickly check an answer to a problem to be sure you've used the calculator correctly.

Table A.1

Number	Exponential Form
1	1×10^0
10	1×10^1
100	1×10^2
1000	1×10^3
10,000	1×10^4
100,000	1×10^5
1,000,000	1×10^6
0.1	1×10^{-1}
0.01	1×10^{-2}
0.001	1×10^{-3}
0.000 1	1×10^{-4}
0.000 01	1×10^{-5}
0.000 001	1×10^{-6}
0.000 000 1	1×10^{-7}

The Meaning of Positive and Negative Exponents

Positive Exponents

Suppose you come across a number such as 6.4×10^4. This is just an alternative way of writing 64,000. In other words, the number 6.4 is multiplied by 10 four times.

$$6.4 \times 10^4 = 6.4 \times 10 \times 10 \times 10 \times 10 = 64{,}000$$

Instead of actually writing out all of these 10s, notice that the decimal point is simply moved four places to the right in going from 6.4×10^4 to 64,000. Here are a few other examples. Study them to see how the decimal point changes.

$$53.476 \times 10^2 = 5347.6$$
$$0.0016 \times 10^5 = 160$$
$$0.000056 \times 10^3 = 0.056$$

Here is another example that more forcefully shows the value of expressing a number in scientific notation.

$$\begin{aligned} &602{,}000{,}000{,}000{,}000{,}000{,}000{,}000 \\ &\quad = 6.02 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times \\ &\qquad 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \\ &\quad = 6.02 \times 10^{23} \end{aligned}$$

(This is Avogadro's number, which is the number of atoms in 12.0 g of carbon.)

In some calculations it is helpful to rewrite large numbers in scientific notation format. To do this, count the number of places you would have to move the decimal point to the left to put it just after the first digit in the number. For example, you would have to move the decimal point four places to the left in the following number.

$$6\ \underset{\underset{4}{\curvearrowleft}}{0}\ \underset{\underset{3}{\curvearrowleft}}{5}\ \underset{\underset{2}{\curvearrowleft}}{3}\ \underset{\underset{1}{\curvearrowleft}}{0}$$

Therefore, we can rewrite 60530 as 6.0530×10^4. Thus the number of moves equals the exponent.

Sometimes it is necessary to change a number from one exponential form to another. For example, suppose we wish to re-express the number 6.0530×10^4 as something times 10^2.

$$6.0530 \times 10^4 = \boxed{} \times 10^2$$

What number goes in the box? Although there are rules that you could learn, it is better to think it through as follows. The number 6.0530×10^4 is a product of two parts, 6.0530 and 10^4. Together they equal 60530. We want to change the exponential part to 10^2, which means the exponential part of the product is becoming *smaller*. The only way the product can remain equal to 60530 is if the decimal part becomes *larger*. Since we are decreasing the exponential part by a factor of 100 (i.e., 10^2), we must increase the decimal part by a factor of 100, which means we change it from 6.0530 to 605.30. Therefore,

$$6.0530 \times 10^4 = \boxed{605.30} \times 10^2$$

Negative Exponents

A negative exponent tells us to take the reciprocal of the quantity and raise it to the power expressed in the exponent. Thus, x^{-1} means $1/x$, and x^{-5} means $1/x^5$.

$$x^{-1} = \frac{1}{x} \qquad x^{-5} = \frac{1}{x^5}$$

Now, imagine you have just encountered a number such as 1.4×10^{-4}. This is an alternative way of writing

$$\frac{1.4}{10 \times 10 \times 10 \times 10}$$

Thus, a negative exponent tells us how many times to divide by ten. Dividing by ten, of course, can be done by simply moving the decimal point. Thus, 1.4×10^{-4} can be re-expressed as 0.00014. Notice that the decimal point is four places to the *left* of the 1. Here are some examples of numbers expressed as negative exponentials and their equivalents.

$$3567.9 \times 10^{-3} = 3.5679$$
$$0.01456 \times 10^{-2} = 0.0001456$$
$$45691 \times 10^{-3} = 45.691$$

To express a number smaller than 1 in scientific notation, we count the number of places the decimal has to be moved to put it to the right of the first nonzero digit. The number that we count equals the negative exponent. For example, you would have to move the decimal point five places to the right to put it to the right of the first nonzero digit in

$$0.\underbrace{00006}_{\text{5 places}}8901$$

This number can be re-expressed as 6.8901×10^{-5}.

Multiplying Numbers Written in Exponential and Scientific Notation

The real value of exponential forms of numbers comes in carrying out multiplications and divisions of large and small numbers. Suppose we want to multiply 1000 by 10000. Doing this by a long process fills the page with zeros (and some ones). But notice the following relationships.

Numbers	1000	×	10000		
	[10 × 10 × 10]	×	[10 × 10 × 10 × 10]	=	10,000,000
Exponential form	10^3	×	10^4	=	10^7
Exponents	3	+	4	=	7

If we *add* 3 and 4, the exponents of the exponential forms of 1000 and 10000, we get the exponent for the answer. Suppose we want to multiply 4160 by 20000. If we re-express each number in scientific notation we have

Multiply these parts.

$$(4.16 \times 10^3) \times (2.00 \times 10^4)$$

Multiply these parts.

This now simplifies to

$$(4.16 \times 2.00) \times [10^3 \times 10^4]$$

The answer can be easily worked without losing the location of the decimal point. The exponents are added to give the exponent on 10 in the answer, and the numbers 4.16 and 2.00 are multiplied. The product is 8.32×10^7. Thus there are two steps in multiplying numbers that are written in scientific notation.

1. Multiply the decimal parts of the numbers (the parts that precede the 10s).
2. Add the exponents of the 10s algebraically to obtain the exponent on the 10 in the answer.

Dividing Numbers Written in Exponential or Scientific Notation

Suppose we want to divide 10,000,000 by 1000. Doing this by long division would be primitive to say the least. It is much easier using exponential notation, where $10{,}000{,}000 = 10^7$ and $1000 = 10^3$. Notice the following relationships.

$$\frac{10{,}000{,}000}{1000} = 10{,}000 \qquad \frac{10^7}{10^3} = 10^4 = 10{,}000$$

The exponent in the result is (7 – 3). So, to divide numbers in exponential form, we subtract the exponent on 10 in the denominator from the exponent on 10 in the numerator.

To extend this operation one step, let's divide 0.00468 by 0.0000400. The answer can be obtained as follows, expressing the numbers in scientific notation.

$$\frac{4.68 \times 10^{-3}}{4.00 \times 10^{-5}} = \frac{4.68}{4.00} \times 10^{[(-3)-(-5)]}$$
$$= 1.17 \times 10^2$$

Notice that the division proceeds in two steps.

1. Carry out the division of the numbers standing before the 10s.
2. Algebraically subtract the exponent in the denominator from the exponent in the numerator.

Estimating Answers by Mental Arithmetic

Often, in working out chemistry problems, we find it necessary to perform a series of multiplications and divisions. These calculations are most easily handled using a calculator, but to check the answer quickly, we can do some simple mental arithmetic. For example, suppose that in solving a problem we performed the following arithmetic.

$$\frac{(1.908 \times 10^3) \times (4.56 \times 10^{-3}) \times (4.52 \times 10^7)}{(1.664 \times 10^{-1}) \times (2.34 \times 10^9) \times (3.02 \times 10^2)} = 3.34 \times 10^{-3} \text{ (rounded)}$$

To perform a check on the arithmetic to see whether the answer is "in the right ball park," we first separate the powers of ten from the other numbers. (You don't actually have to rewrite the problem setup; we're doing so here to make the procedure clearer.)

$$\frac{(1.908) \times (4.56) \times (4.52)}{(1.664) \times (2.34) \times (3.02)} \times \frac{(10^{3}) \times (10^{-3}) \times (10^{7})}{(10^{-1}) \times (10^{9}) \times (10^{2})}$$

Next, let's check the exponential part of the calculation by combining the powers of 10.

$$\begin{aligned}\text{exponential part} &= 10^{[(3-3+7)-(-1+9+2)]}\\ &= 10^{-3}\end{aligned}$$

This agrees with the results obtained with the calculator, so we know our answer is not unreasonable. If we want to check the rest of the math, we need to estimate the results of the arithmetic involving the pre-exponential parts of the numbers

$$\frac{(1.908) \times (4.56) \times (4.52)}{(1.664) \times (2.34) \times (3.02)}$$

We do this by rounding off the numbers so we can do the arithmetic in our heads. Let's round 1.908 to 2. The next two numbers are both close to 4.5, so we will round one of them down and the other up, hoping to cancel rounding errors: 4.56 becomes 4 and 4.52 becomes 5. Similar rounding applied to the numbers in the denominator gives us the following:

$$\frac{(1.908) \times (4.56) \times (4.52)}{(1.664) \times (2.34) \times (3.02)} \approx \frac{2 \times 4 \times 5}{2 \times 2 \times 3} = \frac{40}{12} = \frac{10}{3} \approx 3.3$$

So, our rough arithmetic gives us an answer of 3.3×10^{-3}, which is almost exactly the answer we obtained using the calculator.

Adding or Subtracting Numbers in Scientific Notation

The important thing to remember here is that to perform the arithmetic, both numbers must have the same power of 10. If they're not given that way, then you have to convert one to have the same exponent on 10 as the other. For example, suppose we had to add the two measured distances, 2.36×10^{5} cm and 5.08×10^{3} cm. We could change 5.08×10^{3} cm to have the exponential part equal 10^{5}, or we could change 2.36×10^{5} cm to have the exponential part equal 10^{3}.

$$\begin{array}{r} 2.36 \times 10^{5} \\ \underline{0.0508 \times 10^{5}} \\ 2.41 \times 10^{5} \end{array} \qquad\qquad \begin{array}{r} 236 \times 10^{3} \\ \underline{5.08 \times 10^{3}} \\ 241 \times 10^{3} \end{array}$$

Notice that in both cases, we have applied the rules for significant figures as they apply to addition and subtraction, given on page 44.

A.2 | Logarithms

A **logarithm** is simply an exponent. For example, if we have an expression

$$N = a^{b}$$

we see that to obtain N we must raise a to the b power. The exponent b is said to be the logarithm of N; it is the exponent to which we must raise a, which we call the *base*, to obtain the number N.

$$\log_{a} N = b$$

We can define a logarithm system for any base we want. For example, if we choose the base 2, then

$$\log_2 8 = 3$$

which means that to obtain the number 8, we must raise the base (2) to the third power.

$$8 = 2^3$$

The most frequently encountered logarithm systems in the sciences are *common logarithms* and *natural logarithms*, which are discussed separately below. However, for any system of logarithms there are some useful relationships that evolve from the behavior of exponents in arithmetic operations. We encounter these at various times throughout the sciences, so it is important that you are familiar with them.

For Multiplication:

$$\begin{array}{ll} \text{If} & N = A \times B \\ \text{then} & \log N = \log A + \log B \end{array}$$

For Division:

$$\begin{array}{ll} \text{If} & N = \dfrac{A}{B} \\ \text{then} & \log N = \log A - \log B \end{array}$$

For Exponentials:

$$\begin{array}{ll} \text{If} & N = A^b \\ \text{then} & \log N = b \log A \end{array}$$

Common Logarithms

The **common logarithm** or **log$_{10}$** of a number N is the exponent to which 10 must be raised to equal the number N. Thus, if

$$N = 10^x$$

then the common logarithm of N, or **log$_{10}$ N**, is simply x.

$$\log_{10} N = \log N = x$$

As mentioned earlier, there is another kind of logarithm called a **natural logarithm** that we'll take up later. However, when we use the terms "logarithm" or "log N" without specifying the base, we always mean common logarithms related to the base 10, as indicated above.

If N is just 10 raised to a power, finding the logarithm is simple. For example, suppose we want to find the logarithm of 10^{18}.

$$\log 10^{18} = ?$$

This expression is asking, "To what power do we raise 10 to obtain 10^{18}?" The answer, of course, is 18. (We have to raise 10 to the power 18 to obtain 10^{18}.)

$$\log 10^{18} = 18$$

Here are a few more examples.

$$\begin{array}{lll} N = 10 = 10^1 & & \log N = 1 \\ = 100 = 10^2 & & = 2 \\ = 0.1 = 10^{-1} & & = -1 \\ = 0.0001 = 10^{-4} & & = -4 \end{array}$$

The logarithms of these numbers were easy to figure out by just using the definition of logarithms, but usually it isn't this simple. For example, what is the value of x in the following equations?

$$4.23 = 10^x$$
$$\log 4.23 = x$$

In other words, to what power of x must we raise 10 to obtain 4.23? Obviously, the exponent is not a whole number. Therefore, to determine the value of x we use a scientific calculator. We will have more to say about this in Section A.5.

Natural Logarithms

In the sciences there are many phenomena in which observed quantities are related to each other logarithmically, which means that there is an exponential relationship between them. However, this exponential relationship does not involve 10 raised to a power. Instead it involves powers of a number symbolized by the letter e, which is said to be the base of the system of natural logarithms.

The quantity e is derived from calculus and is an irrational number, just like another quantity you are familiar with, π. This means that e is a nonrepeating decimal. To eight significant figures its value is

$$e = 2.7182818\ldots$$

To truly appreciate the significance of this number and the system of logarithms based on it, you must have a good foundation in calculus. A discussion of calculus is beyond the scope of this text, so we will not attempt to explain the origin of the value of e further. Nevertheless, we can still use the results and discuss the system of **natural logarithms** that has the number e as its base.

Natural logarithms use the symbol **ln** instead of log. Thus, if the number N equals e^x,

$$N = e^x$$

then

$$\log_e N = \ln N = x$$

Scientific calculators have the ability to calculate natural logarithms and their corresponding *antilogarithms*. This is discussed in Section A.5 of this appendix. There is a simple relationship between common and natural logarithms. To four significant figures,

$$\ln N = 2.303 \log N$$

In other words, to find ln N, simply find the common log of N and multiply it by 2.303.

A.3 | Graphing

One of the most useful ways of describing the relationship between two quantities is by means of a graph. It allows us to obtain an overall view of how one quantity changes when the other changes. Constructing graphs from experimental data, or from data calculated from an equation, is therefore a common operation in the sciences, so it is important that you understand how to present data graphically. Let's look at an example.

Suppose that we wanted to know how the volume of a given amount of gas varies as we change its pressure. In Chapter 11 we find an equation that gives the pressure–volume relationship for a fixed amount of gas at a constant temperature,

$$PV = \text{constant} \tag{A.1}$$

where P = pressure and V = volume. For calculations, this equation can be used in two ways. If we solve for the volume, we get

$$V = \frac{\text{constant}}{P} \tag{A.2}$$

Knowing the value of the constant for a given gas sample at a given temperature allows us to calculate the volume that the gas occupies at any particular pressure. Simply substitute in the values for the constant and the pressure and compute the volume.

Equation A.1 can also be solved for the pressure.

$$P = \frac{\text{constant}}{V} \tag{A.3}$$

From this equation the pressure corresponding to any particular volume can be calculated.

Now, suppose, that we want to see graphically how the pressure and volume of a gas are related as the pressure is raised from 1.0 to 10.0 atm in steps of 1.0 atm. Let's also suppose that for this sample of gas the value of the constant in our equation is 0.25 L atm. To construct the graph we first must decide how to label and number the axes.

Usually, the horizontal axis, called the **abscissa**, is chosen to correspond to the **independent variable**—the variable whose values are chosen first and from which the values of the **dependent variable** are determined. In our example, we are choosing values of pressure (1.0 atm, 2.0 atm, etc.), so we will label the abscissa "pressure." We will also mark off the axis evenly from 1.0 to 10.0 atm, as shown in Figure A.1. Next we put the label "volume" on the vertical axis (the ordinate). Before we can number this axis, however, we need to know over what range the volume will vary. Using Equation A.2 we can calculate the data in Table A.2, and we see that the volume ranges from a low of 0.025 L to a high of 0.25 L. We can therefore mark off the ordinate evenly in increments of 0.025 L, starting at the bottom with 0.025 L. Notice that in labeling the axes we have indicated the units of P and V in parentheses.

Next we plot the data as shown in Figure A.2. To clearly show each plotted point, we use a small circle that has its center located at the coordinates of the point. Then we draw a *smooth* curve through the points.

Sometimes, when plotting experimentally measured data, the points do not fall exactly on a smooth line (Figure A.3). However, nature generally is not irregular even though that's what the data appear to suggest. The fluctuations are usually due to experimental error of some sort. Therefore, rather that draw an irregular line connecting all the data points (the dashed line), we draw a smooth curve that passes as close as possible to all of the points, even though it may not actually pass through any of them.

Table A.2

Pressure (atm)	Volume (L)
1.0	0.25
2.0	0.125
3.0	0.083
4.0	0.062
5.0	0.050
6.0	0.042
7.0	0.036
8.0	0.031
9.0	0.028
10.0	0.025

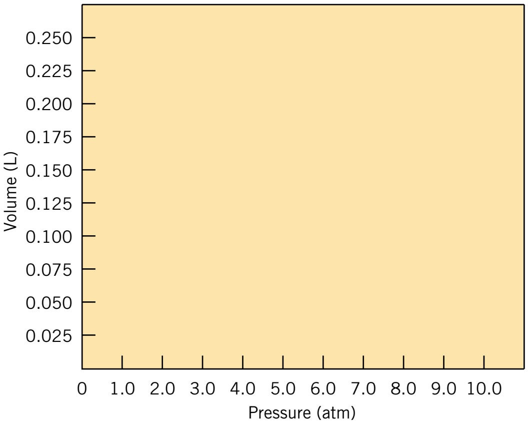


Figure A.1 | Choosing and labeling the axes of a graph.

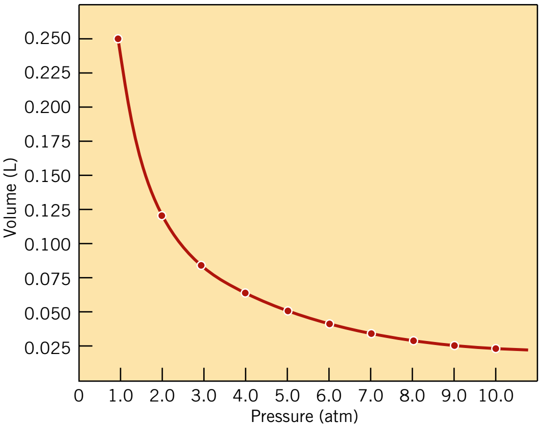

Figure A.2 | Plotting points and drawing the curve.

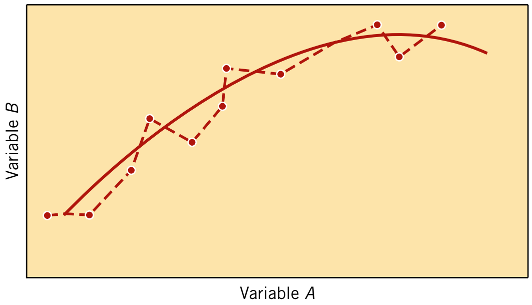

Figure A.3 | Experimental data do not all fall on a smooth curve when they are plotted because they contain experimental error. A smooth curve is drawn as close to all of the data points as possible, rather than the jerky dashed line.

Slope

One of the properties of curves and lines on a graph is their *slope* or steepness. Consider Figure A.4, which is a straight line drawn on a set of xy coordinate axes. The slope of the line is defined as the change in y, Δy, divided by the change in x, Δx.

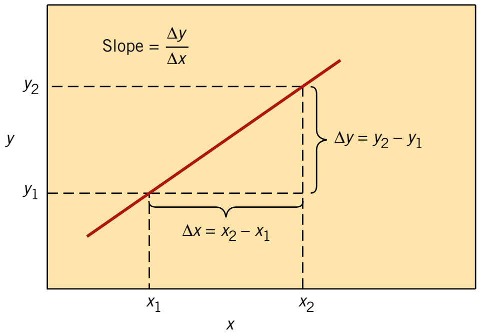

Figure A.4 | Determining the slope of a straight line. Two points are chosen on the line and Δx and Δy are determined. The ratio $\Delta x / \Delta y$ is the slope of the line.

$$\text{slope} = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$$

Curved lines have slopes too, but the slope changes from point to point on the curve. To obtain the slope graphically, we can draw a line that is tangent to the curve at the point where we want to know the slope. The slope of this tangent is the same as the slope of the curve at this point. In Figure A.5 we see a curve for which the slope is determined at two different points. At point M the curve is rising steeply and $\Delta y / \Delta x$ for the tangent is large. At point N the curve is rising less steeply, and $\Delta y / \Delta x$ for the tangent at N is small. Therefore, the slope at M is larger than the slope at N.

Straight Line Graphs

A type of graph that scientists find especially useful is a straight line graph—one similar to Figure A.4. A straight line is obtained when we plot an equation with the general form

$$y = mx + b$$

where m is the slope of the line and b is the intercept of the line with the y axis (where $x = 0$). Usually, the experimental data correspond to the x and y values. When the data are plotted, the slope and intercept can be obtained from the graph. Let's look at an example.

In Figure A.2 we plotted the P-V data in Table A.2. Pressure and volume for a gas are related by the following equation, obtained by solving Equation A.1 for P.

$$P = \frac{\text{constant}}{V} \tag{A.4}$$

Let's rewrite this equation as follows, noting it's similarity of the equation for a straight line.

$$\begin{array}{ccccccc} P & = & (\text{constant}) & \frac{1}{V} & + & 0 \\ \downarrow & & \downarrow & \downarrow & & \downarrow \\ y & = & m & x & + & b \end{array}$$

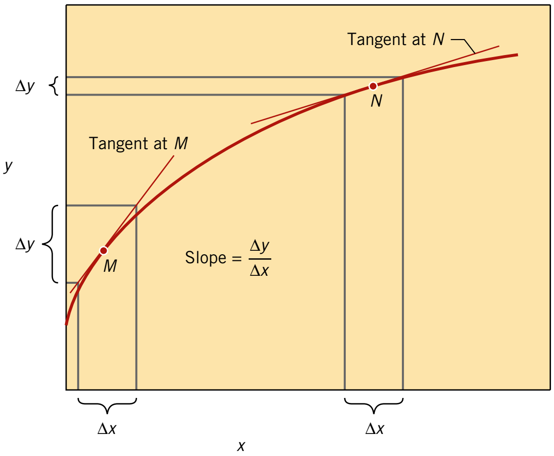

Figure A.5 | For a given Δx, Δy is much larger at M than it is at N. Therefore, the slope at M is larger than at N.

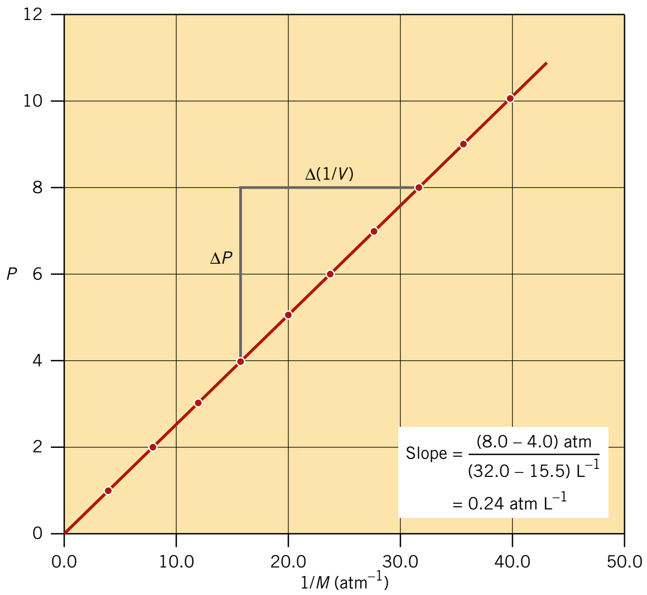

Figure A.6 | A graph of *P* versus 1/*V*.

Table A.3 **Data for a graph of P versus 1/V using values from Table A.2**

P (atm)	1/*V* (L^{-1})
1	4.0
2	8.0
3	12.0
4	16.1
5	20.0
6	23.8
7	27.8
8	32.3
9	35.7
10	40.0

This tells us that if we plot P versus $1/V$, we should obtain a straight line with a slope that's equal to the constant in Equation A.4, and with an intercept of zero (i.e., the line should pass through zero). Table A.3 contains P and $1/V$ data obtained from the data in Table A.2. These data are plotted in Figure A.6. The slope of the line is obtained as described in Figure A.4 by choosing two points on the graph, estimating x and y values, and calculating the slope. The results are also shown in Figure A.6.

Sometimes the relationship between x and y is as follows,

$$y = A\,e^{Bx}$$

where e is the base of the natural logarithm system. In such situations, we take the natural logarithm of both sides of the equation,

$$\ln y = \ln A + B\,x$$

which we can rearrange as

$$\begin{array}{cccccc} \ln y & = & B & x & + & \ln A \\ \downarrow & & \downarrow & \downarrow & & \downarrow \\ y & = & m & x & + & b \end{array}$$

Notice how we have once again obtained an equation that follows the form of a straight line, so by plotting $\ln y$ versus x, we should obtain a straight line with a slope equal to B and an intercept of $\ln A$.

A.4 | Method of Successive Approximations

This section of the appendix applies primarily to problems associated with Chapters 15 and 17 where we discuss problems involved with chemical equilibria.

In nearly all of the examples described in Chapter 17, simplifications in the algebra are possible because K_a or K_b are very small and the concentration of the solute is relatively large. However, there are instances when the simplifications are not justified and other methods are needed to solve the algebra. For example, suppose that in working a problem dealing with a weak acid equilibrium we reach the point where we have to solve the following equation for *x*.

$$\frac{x^2}{(0.010 - x)} = 1.4 \times 10^{-3} \tag{A.5}$$

For this problem, the usual simplifications do not work, so we are not justified in assuming that $(0.010 - x) \approx 0.010$. As a result, we have to deal with solving a quadratic equation. There are two ways to go about it. In one approach, we solve for *x* using the quadratic formula, as described on page 725. For Equation A.5, applying the quadratic formula yields $x = 3.1 \times 10^{-3}$.

The second approach is to apply a procedure called the *method of successive approximations.* This method is not only much faster than using the quadratic formula, particularly with a scientific calculator, but it is also just as accurate. The procedure is outlined in Figure A.7, which you should follow as we apply the method to solving Equation A.5 for *x*.

Step 1 We apply the simplifying approximation to Equation A.5, even though we know it is not really applicable. Doing this, we obtain the following:

$$\frac{x^2}{(0.010 - x)} \approx \frac{x^2}{0.010} = 1.4 \times 10^{-3}$$

for which we obtain the solution $x = 3.7 \times 10^{-3}$. We call this quantity, $x = 3.7 \times 10^{-2}$, our *first approximation.*

Step 2 We substitute $x = 3.7 \times 10^{-3}$ (our first approximation) into the term in the denominator, $(0.100 - x)$, and then recompute *x*. This gives us

$$\frac{x^2}{(0.010 - 0.0037)} = 1.4 \times 10^{-3}$$

or

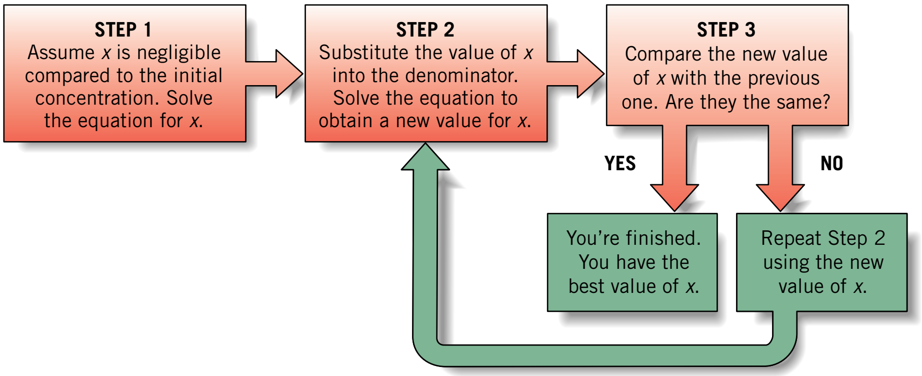
$$x^2 = (0.006) \times 1.4 \times 10^{-3}$$

Taking only the positive root,

$$x = 2.9 \times 10^{-3} \; (\textit{second approximation})$$

We call $x = 2.9 \times 10^{-3}$ our *second approximation.*

Step 3 We compare the second approximation to the first and we see they are not the same, so we repeat Step 2.



STEP 1
Assume *x* is negligible compared to the initial concentration. Solve the equation for *x*.
STEP 2
Substitute the value of *x* into the denominator. Solve the equation to obtain a new value for *x*.
STEP 3
Compare the new value of *x* with the previous one. Are they the same?
YES
NO
You're finished. You have the best value of *x*.
Repeat Step 2 using the new value of *x*.

Figure A.7 | Steps in the method of successive approximations.

Step 2 again We substitute $x = 2.9 \times 10^{-3}$ (our second approximation) into the term in the denominator, $(0.100 - x)$, and then recompute x. This gives us a *third approximation*,

$$\frac{x^2}{(0.010 - 0.0029)} = 1.4 \times 10^{-3}$$
$$x^2 = (0.007) \times 1.4 \times 10^{-3}$$
$$x = 3.1 \times 10^{-3} \quad (\textit{third approximation})$$

Step 3 again The third approximation is not the same as the second approximation, so we repeat Step 2 again.

Step 2 again We substitute $x = 3.1 \times 10^{-3}$ (our third approximation) into the term in the denominator, $(0.100 - x)$, and then recompute x. This gives us

$$\frac{x^2}{(0.010 - 0.0031)} = 1.4 \times 10^{-3}$$
$$x^2 = (0.007) \times 1.4 \times 10^{-3}$$
$$x = 3.1 \times 10^{-3} \quad (\textit{fourth approximation})$$

Step 3 again When we compare the third and fourth approximations, we see that they are identical, so we are finished. The method of successive approximations tells us that $x = 3.1 \times 10^{-3}$.

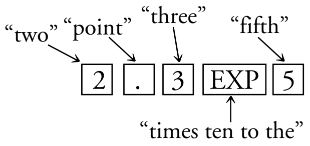
First, you might notice that the answer obtained by the method of successive approximations is identical to that obtained using the quadratic formula (which also gave $x = 3.1 \times 10^{-3}$). Also notice that the second pass through Step 2 gave a smaller correction than the first. Each succeeding approximation differs from the preceding one by a smaller and smaller amount. We stop the calculation when the difference between two approximations is insignificant. Try this approach by working Problem 17.131 on page 827.

A.5 | Tips on Using Scientific Calculators

Scientific Calculators and Scientific Notation

Scientific calculators give you the ability to easily perform arithmetic of all kinds, and they are especially useful when you have to deal with large or small numbers expressed as exponentials. As you would expect, addition, subtraction, multiplication, and division are performed with the keys $\boxed{+}$, $\boxed{-}$, $\boxed{\times}$, and $\boxed{\div}$, respectively.[1] However, students often have difficulty in properly entering numbers in scientific notation, so let's take a detailed look at this.

To deal with numbers in scientific notation, such as 2.3×10^5 or 6.7×10^{-12}, calculators have a special key often labeled EXP or EE. If we read the number 2.3×10^5 as "two point three times ten to the fifth," the EXP (or EE) key should be read as ". . . times ten to the . . ." Thus the sequence of keys that enter the number 2.3×10^5 is



---

[1] You're probably familiar with the old adage: "When all else fails, read the instructions!" We strongly encourage you to read the *Instruction Manual* that came with your calculator.

Try this on your own calculator and check to be sure that the number is correctly displayed after you've entered it.[2] If not, check the instruction booklet that came with the calculator or ask your instructor for help.

When entering a number such as 6.7×10^{-12}, be sure to press the "change sign" or "+/−" key after pressing the EXP key. Calculators will not give the correct entry if the "minus" key is pressed instead of the "+/−" key. For example, clear the display and then try the following sequence of keystrokes on your calculator.

$$\boxed{6}\ \boxed{.}\ \boxed{7}\ \boxed{\text{EXP}}\ \boxed{+/-}\ \boxed{1}\ \boxed{2}$$

If you wish to multiply these two numbers together, enter the first one, press the $\boxed{\times}$ key, then enter the second number, and finally press the $\boxed{=}$ key. The answer displayed on the calculator should be 1.541×10^{-6}.

$$(2.3 \times 10^{5}) \times (6.7 \times 10^{-12}) = 1.541 \times 10^{-6}$$

Chain Calculations

It is not uncommon to have to calculate the value of a fraction in which there is a string of numbers that must be multiplied together in the numerator and another string of numbers to be multiplied together in the denominator. For example,

$$\frac{5.0 \times 7.3 \times 8.5}{6.2 \times 2.5 \times 3.9}$$

Many students will compute the value of the numerator and write down the answer, then compute the value of the denominator and write it down, and finally divide the value of the numerator by the value of the denominator (whew!). Although this gives the correct answer, there is a simpler way to do the arithmetic that doesn't require writing down any intermediate values. The procedure is as follows:

1. Enter the first value from the numerator (5.0).
2. Any of the other values from the numerator are entered by *multiplication* and any of the values from the denominator are entered by *division*.

The following is one sequence that gives the answer.

$$5.0 \times 7.3 \times 8.5 \div 6.2 \div 2.5 \div 3.9 = 5.13234\ldots$$

Notice that each value from the denominator is entered by division. It also doesn't matter in what sequence the numbers are entered. The following gives the same answer.

$$5.0 \div 6.2 \times 7.3 \div 2.5 \div 3.9 \times 8.5 = 5.13234\ldots$$

Logarithms and Antilogarithms

Your scientific calculator works with both common logarithms and natural logarithms. To find the common log of a number, enter the number in the calculator and press the $\boxed{\text{log}}$ or $\boxed{\text{LOG}}$ button. Try this for the following and check your results. (The values here are rounded so they have the same number of digits after the decimal point as there are significant figures in the number. This is the rule for significant figures in logarithms as described below):

$$\log 12.35 = 1.0917 \text{ (rounded)}$$

$$\log (3.70 \times 10^{-4}) = -3.432 \text{ (rounded)}$$

---

[2] Sometimes students make the mistake of trying to enter a number such as 2.3×10^{5} as follows: $\boxed{2}\ \boxed{.}\ \boxed{3}\ \boxed{\times}\ \boxed{1}\ \boxed{0}\ \boxed{\text{EXP}}\ \boxed{5}$. What this series of operations accomplishes is to multiply 2.3 by 10, giving 23, and then entering the exponential notation 10^{5}.

$$\boxed{2}\ \boxed{.}\ \boxed{3}\ \boxed{\times}\ \boxed{1}\ \boxed{0}\ \boxed{\text{EXP}}\ \boxed{5} = 23 \times 10^{5}$$

This is certainly not what was intended. If you are doing arithmetic and your answers are off by powers of 10, check to be sure you're entering the numbers correctly into the calculator.

Obtaining the antilogarithm is equally easy. For the first number above, 12.35 is the antilog of 1.0917, which means that

$$12.35 = 10^{1.0917}$$

Some calculators have a key labeled $\boxed{10^x}$; others use a combination of an inverse function key, usually labeled $\boxed{\text{INV}}$, and the key used to obtain the logarithm. Thus, entering the value 1.0917 and pressing either $\boxed{10^x}$ or the sequence $\boxed{\text{INV}}$ $\boxed{\text{log}}$ yields the value 12.35. Try it.

To obtain natural logarithms of a number we use key labeled either $\boxed{\ln x}$ or $\boxed{\text{LN}}$ or sometimes $\boxed{\ln}$. Thus the natural logarithm of 12.35 is obtained by entering the number and pressing the $\boxed{\ln x}$ key. Try it.

$$\ln 12.35 = 2.5137 \text{ (rounded)}$$

The value 12.35 is the antinatural logarithm (antiln) of 2.5137, which means

$$12.35 = e^{2.5137}$$

Therefore, to obtain the antilogarithm of 2.5137, we enter the number into the calculator and press either the key labeled $\boxed{e^x}$ or the sequence $\boxed{\text{INV}}$ $\boxed{\ln x}$. Try it.

$$\text{antiln } 2.5137 = 12.35$$

Significant Figures and Logarithms

The logarithm of a number is composed of two parts. There is a part that comes before the decimal point (which is called the *characteristic*) and a part that comes after the decimal point (which is called the *mantissa*). Let's look at an example, for the moment keeping all the digits shown on the calculator.

$$\log(4.23 \times 10^5) = \overset{\substack{\text{characteristic} \\ |}}{5}.\underbrace{626340367}_{\text{mantissa}}$$

The characteristic comes from the exponent on the 10 ($\log 10^5 = 5$) and is an exact number, so it need not be considered for the purposes of significant figures. The mantissa, on the other hand, is the logarithm of the number that precedes the power of ten [$\log(4.23) = 0.626340367$]. The 4.23 has three significant figures, so the mantissa should also have three significant figures. Therefore, rounded correctly,

$$\log(4.23 \times 10^5) = 5.626 \text{ (rounded)}$$

This leads to the rule that *when we take the logarithm of a quantity, the number of decimal places shown in the logarithm should equal the number of significant figures in the quantity*. Here is another example.

$$\begin{aligned} \log(5.246 \times 10^{-7}) &= -6.280171714 \\ &= -6.2802 \text{ (rounded correctly)} \end{aligned}$$

The quantity 5.246×10^{-7} has four significant figures, so we round off the logarithm to the fourth decimal place.

When taking an antilogarithm, the same relationship applies. If we take the antilog of 6.557, the answer will have three significant figures because the logarithm has three digits after the decimal.

$$\text{antilog}(6.557) = 3.61 \times 10^6 \text{ (rounded correctly)}$$

The same rules for significant figures apply for both common and natural logarithms.

Powers and Roots

Squares and square roots are handled easily with keys labeled $\boxed{x^2}$ and $\boxed{\sqrt{x}}$. For higher powers and higher roots (e.g., cube roots or fourth roots) we use the key that on most scientific calculators is labeled $\boxed{x^y}$. To use this function, we must enter two values—the number and its exponent. For example, to raise the number 2.6 to the 5th power,

$$(2.6)^5$$

we enter the number 2.6, press the $\boxed{x^y}$ key enter the value of the exponent (5), and then press either the "equals" key or the next function key desired if we are performing a chain calculation. Thus, the sequence

$$\boxed{2}\ \boxed{.}\ \boxed{6}\ \boxed{x^y}\ \boxed{5}\ \boxed{=}$$

produces the result 118.81376 on the display of the calculator. Therefore,

$$(2.6)^5 = 118.81376$$

To take a root, the procedure is quite similar, because we make use of the relationship

$$\sqrt[n]{(\text{number}} = (\text{number})^{1/n}$$

Thus, the cube root of a number such as 56.4 is obtained as

$$\sqrt[3]{56.4} = (56.4)^{1/3} = (56.4)^{0.333333\ldots}$$

In other words, we raise 56.4 to the one-third power, for which the decimal equivalent is 0.3333333 … (with as many threes as will fit on the display). Let's try it. Clear the display and enter the number 56.4. Next, press the $\boxed{x^y}$ key. Then enter 0.33333 with as many threes after the decimal point as you can. Finally, press the "equals" key. The answer should be 3.834949 …. If we had wanted to take the 5th root of 56.4, we would raise the number to the 1/5 power, or 0.20. Try it. You should get 2.24004 … as the answer.

Some calculators have a key labeled $\boxed{x^{1/y}}$, which makes taking a root even easier. Thus, to take the 5th root of 56.4, we would enter the number 56.4, then press the $\boxed{x^{1/y}}$ key, and then press 5. Once again, the answer displayed should be 2.24004.

Appendix B

Answers to Practice Exercises and Selected Review Problems

Chapter 1

Practice Exercises

1.1 **(a)** 1 S, 6 F **(b)** 4 C, 12 H, 2 N **(c)** 3 Ca, 2 P, 8 O **(d)** 1 Co, 2 N, 12 O, 12 H. **1.2** **(a)** 2 N nitrogen, 4 H hydrogen, 3 O oxygen. **(b)** 1 Fe iron, 1 N nitrogen, 4 H hydrogen, 2 S sulfur, 8 O oxygen. **(c)** 1 Mo molybdenum, 2 N nitrogen, 11 O oxygen, 10 H hydrogen. **(d)** 6 C carbon, 4 H hydrogen, 1 Cl chlorine, 1 N nitrogen, 2 O oxygen. **1.3** C_2H_7N, CH_3NHCH_3. **1.4** Reactants: 4 N, 12 H, and 6 O; Products: 4 N, 12 H, and 6 O. **1.5** Reactants: 6 N, 42 H, 2 P, 20 O, 3 Ba, 12 C; Products: 3 Ba, 2 P, 20 O, 6 N, 42 H, 12 C; Reaction is balanced.

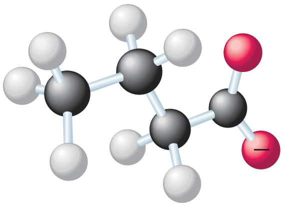
Chapter 5

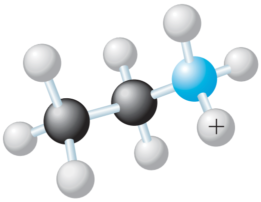
Practice Exercises

5.1 **(a)** $FeCl_3(s) \longrightarrow Fe^{3+}(aq) + 3Cl^-(aq)$
(b) $K_3PO_4(s) \longrightarrow 3K^+(aq) + PO_4{}^{3-}(aq)$
5.2 **(a)** $MgCl_2(s) \longrightarrow Mg^{2+}(aq) + 2Cl^-(aq)$
(b) $Al(NO_3)_3(s) \longrightarrow Al^{3+}(aq) + 3NO_3{}^-(aq)$
(c) $Na_2CO_3(s) \longrightarrow 2Na^+(aq) + CO_3{}^{2-}(aq)$
5.3 Molecular: $(NH_4)_2SO_4(aq) + Ba(NO_3)_2(aq) \longrightarrow$
$BaSO_4(s) + 2NH_4NO_3(aq)$
Ionic: $2NH_4{}^+(aq) + SO_4{}^{2-}(aq) + Ba^{2+}(aq) + 2NO_3{}^-(aq) \longrightarrow$
$BaSO_4(s) + 2NH_4{}^+(aq) + 2NO_3{}^-(aq)$
Net ionic: $Ba^{2+}(aq) + SO_4{}^{2-}(aq) \longrightarrow BaSO_4(s)$
5.4 Molecular: $CdCl_2(aq) + Na_2S(aq) \longrightarrow CdS(s) + 2NaCl(aq)$
Ionic: $Cd^{2+}(aq) + 2Cl^-(aq) + 2Na^+(aq) + S^{2-}(aq) \longrightarrow$
$CdS(s) + 2Na^+(aq) + 2Cl^-(aq)$
Net ionic: $Cd^{2+}(aq) + S^{2-}(aq) \longrightarrow CdS(s)$
5.5 $HCHO_2(aq) + H_2O \longrightarrow H_3O^+(aq) + CHO_2{}^-(aq)$
5.6



$CH_3CH_2CH_2CHOOH(l) + H_2O \longrightarrow$
$CH_3CH_2CH_2COO^-(aq) + H_3O^+(aq)$

5.7 $H_3C_6H_5O_7(s) + H_2O \longrightarrow H_3O^+(aq) + H_2C_6H_5O_7{}^-(aq)$
$H_2C_6H_5O_7{}^-(aq) + H_2O \longrightarrow H_3O^+(aq) + HC_6H_5O_7{}^{2-}(aq)$
$HC_6H_5O_7{}^{2-}(aq) + H_2O \longrightarrow H_3O^+(aq) + C_6H_5O_7{}^{3-}(aq)$
5.8 $(C_2H_5)_3N(aq) + H_2O \longrightarrow (C_2H_5)_3NH^+(aq) + OH^-(aq)$
5.9 $HONH_2(aq) + H_2O \longrightarrow HONH_3{}^+(aq) + OH^-(aq)$
5.10



$CH_3CH_2NH_2(aq) + H_2O \longrightarrow CH_3CH_2NH_3{}^+(aq) + OH^-(aq)$

5.11 $CH_3NH_2(aq) + H_2O \longrightarrow CH_3NH_3{}^+(aq) + OH^-(aq)$
5.12 $HNO_2(aq) + H_2O \longrightarrow H_3O^+(aq) + NO_2{}^-(aq)$
5.13 sodium arsenate **5.14** calcium formate, calcium methanoate **5.15** hydrofluoric acid, sodium fluoride; hydrobromic acid, sodium bromide **5.16** Iodic acid **5.17** $NaHSO_3$, sodium hydrogen sulfite
5.18 $H_3PO_4(aq) + NaOH(aq) \longrightarrow NaH_2PO_4(aq) + H_2O$
sodium dihydrogen phosphate
$NaH_2PO_4(aq) + NaOH(aq) \longrightarrow Na_2HPO_4(aq) + H_2O$
sodium hydrogen phosphate
$Na_2HPO_4(aq) + NaOH(aq) \longrightarrow Na_3PO_4(aq) + H_2O$
sodium phosphate

5.19 Molecular: $Zn(NO_3)_2(aq) + Ca(C_2H_3O_2)_2(aq) \longrightarrow$
$Zn(C_2H_3O_2)_2(aq) + Ca(NO_3)_2(aq)$
Ionic: $Zn^{2+}(aq) + 2NO_3{}^-(aq) + Ca^{2+}(aq) + 2C_2H_3O_2{}^-(aq) \longrightarrow$
$Zn^{2+}(aq) + 2C_2H_3O_2{}^-(aq) + Ca^{2+}(aq) + 2NO_3{}^-(aq)$
Net ionic: No reaction
5.20 **(a)** Molecular: $AgNO_3(aq) + NH_4Cl(aq) \longrightarrow$
$AgCl(s) + NH_4NO_3(aq)$
Ionic: $Ag^+(aq) + NO_3{}^-(aq) + NH_4{}^+(aq) + Cl^-(aq) \longrightarrow$
$AgCl(s) + NH_4{}^+(aq) + NO_3{}^-(aq)$
Net ionic: $Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$
(b) Molecular: $Na_2S(aq) + Pb(C_2H_3O_2)_2(aq) \longrightarrow$
$2NaC_2H_3O_2(aq) + PbS(s)$
Ionic: $2Na^+(aq) + S^{2-}(aq) + Pb^{2+}(aq) + 2C_2H_3O_2{}^-(aq) \longrightarrow$
$2Na^+(aq) + 2C_2H_3O_2{}^-(aq) + PbS(s)$
Net ionic: $S^{2-}(aq) + Pb^{2+}(aq) \longrightarrow PbS(s)$
5.21 Molecular: $2HNO_3(aq) + Ca(OH)_2(aq) \longrightarrow$
$Ca(NO_3)_2(aq) + 2H_2O$
Ionic: $2H^+(aq) + 2NO_3{}^-(aq) + Ca^{2+}(aq) + 2OH^-(aq) \longrightarrow$
$Ca^{2+}(aq) + 2NO_3{}^-(aq) + 2H_2O$
Net ionic: $H^+(aq) + OH^-(aq) \longrightarrow H_2O$
5.22 **(a)** Molecular: $HCl(aq) + KOH(aq) \longrightarrow H_2O + KCl(aq)$
Ionic: $H^+(aq) + Cl^-(aq) + K^+(aq) + OH^-(aq) \longrightarrow$
$H_2O + K^+(aq) + Cl^-(aq)$
Net ionic: $H^+(aq) + OH^-(aq) \longrightarrow H_2O$
(b) Molecular: $HCHO_2(aq) + LiOH(aq) \longrightarrow H_2O + LiCHO_2(aq)$
Ionic: $HCHO_2(aq) + Li^+(aq) + OH^-(aq) \longrightarrow$
$H_2O + Li^+(aq) + CHO_2{}^-(aq)$
Net ionic: $HCHO_2(aq) + OH^-(aq) \longrightarrow H_2O + CHO_2{}^-(aq)$
(c) Molecular: $N_2H_4(aq) + HCl(aq) \longrightarrow N_2H_5Cl(aq)$
Ionic: $N_2H_4(aq) + H^+(aq) + Cl^-(aq) \longrightarrow N_2H_5{}^+(aq) + Cl^-(aq)$
Net ionic: $N_2H_4(aq) + H^+(aq) \longrightarrow N_2H_5{}^+(aq)$
5.23 Molecular: $CH_3NH_2(aq) + HCHO_2(aq) \longrightarrow$
$CH_3NH_3CHO_2(aq)$
Ionic: $CH_3NH_2(aq) + HCHO_2(aq) \longrightarrow$
$CH_3NH_3{}^+(aq) + CHO_2{}^-(aq)$
Net ionic: $CH_3NH_2(aq) + HCHO_2(aq) \longrightarrow$
$CH_3NH_3{}^+(aq) + CHO_2{}^-(aq)$
5.24 Molecular: $2HCHO_2(aq) + Co(OH)_2(s) \longrightarrow$
$Co(CHO_2)_2(aq) + 2H_2O$
Ionic: $2HCHO_2(aq) + Co(OH)_2(s) \longrightarrow$
$2CHO_2{}^-(aq) + Co^{2+}(aq) + 2H_2O$
Net ionic: $2HCHO_2(aq) + Co(OH)_2(s) \longrightarrow$
$2CHO_2{}^-(aq) + Co^{2+}(aq) + 2H_2O$
5.25 **(a)** Formic acid, a weak acid will form.
Molecular: $KCHO_2(aq) + HCl(aq) \longrightarrow KCl(aq) + HCHO_2(aq)$
Ionic: $K^+(aq) + CHO_2{}^-(aq) + H^+(aq) + Cl^-(aq) \longrightarrow$
$K^+(aq) + Cl^-(aq) + HCHO_2(aq)$
Net ionic: $CHO_2{}^-(aq) + H^+(aq) \longrightarrow HCHO_2(aq)$
(b) Carbonic acid will form and it will further dissociate to water and carbon dioxide:
$CuCO_3(s) + 2H^+(aq) \longrightarrow CO_2(g) + H_2O + Cu^{2+}(aq)$
Molecular: $CuCO_3(s) + 2HC_2H_3O_2(aq) \longrightarrow$
$CO_2(g) + H_2O + Cu(C_2H_3O_2)_2(aq)$
Ionic: $CuCO_3(s) + 2HC_2H_3O_2(aq) \longrightarrow$
$CO_2(g) + H_2O + Cu^{2+} + 2C_2H_3O_2{}^-(aq)$
Net ionic: $CuCO_3(s) + 2HC_2H_3O_2(aq) \longrightarrow$
$CO_2(g) + H_2O + Cu^{2+} + 2C_2H_3O_2{}^-(aq)$
(c) No reaction will occur. All acetate salts and nitrate salts are soluble
(d) Insoluble nickel hydroxide will precipitate.
$Ni^{2+}(aq) + 2OH^-(aq) \longrightarrow Ni(OH)_2(s)$

Molecular: $NiCl_2(aq) + 2NaOH(aq) \longrightarrow Ni(OH)_2(s) + 2NaCl(aq)$

Ionic: $Ni^{2+}(aq) + 2Cl^-(aq) + 2Na^+(aq) + 2OH^-(aq) \longrightarrow Ni(OH)_2(s) + 2Na^+(aq) + 2Cl^-(aq)$

Net ionic: $Ni^{2+}(aq) + 2OH^-(aq) \longrightarrow Ni(OH)_2(s)$

5.26 $CuO(s) + 2HNO_3(aq) \longrightarrow Cu(NO_3)_2(aq) + H_2O(l)$

Or

$Cu(OH)_2(s) + 2HNO_3(aq) \longrightarrow Cu(NO_3)_2(aq) + 2H_2O(l)$

5.27 You want to use a metathesis reaction that produces CoS, which is insoluble, and a second product that is soluble. You may want the reactants to be soluble.

$CoCl_2(aq) + Na_2S(aq) \longrightarrow CoS(s) + 2NaCl(aq)$

5.28 1.53 M HNO_3 **5.29** 0.1837 M **5.30** 0.0438 mol HCl

5.31 143 mL of HCl **5.32** 2.11 g $Sr(NO_3)_2$ **5.33** 0.531 g $AgNO_3$

5.34 250.0 mL **5.35** 600 mL of water. **5.36** 31.6 mL H_3PO_4

5.37 26.8 mL NaOH **5.38** 0.40 M Fe^{3+}, 1.2 M Cl^-

5.39 0.750 M Na^+ **5.40** 0.0449 M $CaCl_2$ **5.41** 60.0 mL KOH

5.42 0.605 g Na_2SO_4

5.43 **(a)** 5.41×10^{-3} mol Ca^{2+}

(b) 5.41×10^{-3} mol Ca^{2+}

(c) 5.41×10^{-3} mol $CaCl_2$

(d) 0.600 g $CaCl_2$

(e) 30.0% $CaCl_2$

(f) 70.0 % $MgCl_2$

5.44 0.178 M H_2SO_4 **5.45** 0.0220 M HCl, 0.0803%

Review Problems

5.53 $HClO_4(l) + H_2O \longrightarrow H_3O^+(aq) + ClO_4^-(aq)$

5.55 $N_2H_4(aq) + H_2O \longrightarrow N_2H_5^+(aq) + OH^-(aq)$

5.57 $HNO_2(aq) + H_2O \longrightarrow H_3O^+(aq) + NO_2^-(aq)$

5.59 $H_2CO_3(aq) + H_2O \longrightarrow H_3O^+(aq) + HCO_3^-(aq)$

$HCO_3^-(aq) + H_2O \longrightarrow H_3O^+(aq) + CO_3^{2-}(aq)$

5.61 Molecular: $Na_2S(aq) + Cu(NO_3)_2(aq) \longrightarrow CuS(s) + 2NaNO_3(aq)$

Ionic: $2Na^+(aq) + S^{2-}(aq) + Cu^{2+}(aq) + 2NO_3^-(aq) \longrightarrow CuS(s) + 2Na^+(aq) + 2NO_3^-(aq)$

Net: $Cu^{2+}(aq) + S^{2-}(aq) \longrightarrow CuS(s)$

5.63 **(a)**, **(b)**, and **(d)**.

5.65

(a) Ionic: $3Fe^{2+}(aq) + 3SO_4^{2-}(aq) + 6K^+(aq) + 2PO_4^{3-}(aq) \longrightarrow Fe_3(PO_4)_2(s) + 6K^+(aq) + 3SO_4^{2-}(aq)$

Net: $3Fe^{2+}(aq) + 2PO_4^{3-}(aq) \longrightarrow Fe_3(PO_4)_2(s)$

(b) Ionic: $3Ag^+(aq) + 3C_2H_3O_2^-(aq) + Al^{3+}(aq) + 3Cl^-(aq) \longrightarrow 3AgCl(s) + Al^{3+}(aq) + 3C_2H_3O_2^-(aq)$

Net: $Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$

(c) Ionic: $2Cr^{3+}(aq) + 6Cl^-(aq) + 3Ba^{2+}(aq) + 6OH^-(aq) \longrightarrow 2Cr(OH)_3(s) + 3Ba^{2+}(aq) + 6Cl^-(aq)$

Net: $Cr^{3+}(aq) + 3OH^-(aq) \longrightarrow Cr(OH)_3(s)$

5.67 **(a)** Molecular: $Ca(OH)_2(aq) + 2HNO_3(aq) \longrightarrow Ca(NO_3)_2(aq) + 2H_2O$

Ionic: $Ca^{2+}(aq) + 2OH^-(aq) + 2H^+(aq) + 2NO_3^-(aq) \longrightarrow Ca^{2+}(aq) + 2NO_3^-(aq) + 2H_2O$

Net: $H^+(aq) + OH^-(aq) \longrightarrow H_2O$

(b) Molecular: $Al_2O_3(s) + 6HCl(aq) \longrightarrow 2AlCl_3(aq) + 3H_2O$

Ionic: $Al_2O_3(s) + 6H^+(aq) + 6Cl^-(aq) \longrightarrow 2Al^{3+}(aq) + 6Cl^-(aq) + 3H_2O$

Net: $Al_2O_3(s) + 6H^+(aq) \longrightarrow 2Al^{3+}(aq) + 3H_2O$

(c) Molecular: $Zn(OH)_2(s) + H_2SO_4(aq) \longrightarrow ZnSO_4(aq) + 2H_2O$

Ionic: $Zn(OH)_2(s) + 2H^+(aq) + SO_4^{2-}(aq) \longrightarrow Zn^{2+}(aq) + SO_4^{2-}(aq) + 2H_2O$

Net: $Zn(OH)_2(s) + 2H^+(aq) \longrightarrow Zn^{2+}(aq) + 2H_2O$

5.69 The electrical conductivity would decrease regularly, until one solution had neutralized the other, forming a non-electrolyte:

$Ba^{2+}(aq) + 2OH^-(aq) + 2H^+(aq) + SO_4^{2-}(aq) \longrightarrow BaSO_4(s) + 2H_2O$

Once the point of neutralization had been reached, the addition of excess sulfuric acid would cause the conductivity to increase, because sulfuric acid is a strong electrolyte itself.

5.71 **(a)** $2H^+(aq) + CO_3^{2-}(aq) \longrightarrow H_2O + CO_2(g)$

(b) $NH_4^+(aq) + OH^-(aq) \longrightarrow NH_3(g) + H_2O$

5.73 These reactions have the following "driving forces":

(a) Formation of insoluble $Cr(OH)_3$

(b) Formation of water, a weak electrolyte

5.75 **(a)** Molecular: $3HNO_3(aq) + Cr(OH)_3(s) \longrightarrow Cr(NO_3)_3(aq) + 3H_2O$

Ionic: $3H^+(aq) + 3NO_3^-(aq) + Cr(OH)_3(s) \longrightarrow Cr^{3+}(aq) + 3NO_3^-(aq) + 3H_2O$

Net: $3H^+(aq) + Cr(OH)_3(s) \longrightarrow Cr^{3+}(aq) + 3H_2O$

(b) Molecular: $HClO_4(aq) + NaOH(aq) \longrightarrow NaClO_4(aq) + H_2O$

Ionic: $H^+(aq) + ClO_4^-(aq) + Na^+(aq) + OH^-(aq) \longrightarrow Na^+(aq) + ClO_4^-(aq) + H_2O$

Net: $H^+(aq) + OH^-(aq) \longrightarrow H_2O$

(c) Molecular: $Cu(OH)_2(s) + 2HC_2H_3O_2(aq) \longrightarrow Cu(C_2H_3O_2)_2(aq) + 2H_2O$

Ionic: $Cu(OH)_2(s) + 2H^+(aq) + 2C_2H_3O_2^-(aq) \longrightarrow Cu^{2+}(aq) + 2C_2H_3O_2^-(aq) + 2H_2O$

Net: $Cu(OH)_2(s) + 2H^+(aq) \longrightarrow Cu^{2+}(aq) + 2H_2O$

(d) Molecular: $ZnO(s) + H_2SO_4(aq) \longrightarrow ZnSO_4(aq) + H_2O$

Ionic: $ZnO(s) + 2H^+(aq) + SO_4^{2-}(aq) \longrightarrow Zn^{2+}(aq) + SO_4^{2-}(aq) + H_2O$

Net: $ZnO(s) + 2H^+(aq) \longrightarrow Zn^{2+}(aq) + H_2O$

5.77 **(a)** Molecular: $Na_2SO_3(aq) + Ba(NO_3)_2(aq) \longrightarrow BaSO_3(s) + 2NaNO_3(aq)$

Ionic: $2Na^+(aq) + SO_3^{2-}(aq) + Ba^{2+}(aq) + 2NO_3^-(aq) \longrightarrow BaSO_3(s) + 2Na^+(aq) + 2NO_3^-(aq)$

Net: $Ba^{2+}(aq) + SO_3^{2-}(aq) \longrightarrow BaSO_3(s)$

(b) Molecular: $2HCHO_2(aq) + K_2CO_3(aq) \longrightarrow CO_2(g) + H_2O + 2KCHO_2(aq)$

Ionic: $2H^+(aq) + 2CHO_2^-(aq) + 2K^+(aq) + CO_3^{2-}(aq) \longrightarrow CO_2(g) + H_2O + 2K^+(aq) + 2CHO_2^-(aq)$

Net: $2H^+(aq) + CO_3^{2-}(aq) \longrightarrow CO_2(g) + H_2O$

(c) Molecular: $2NH_4Br(aq) + Pb(C_2H_3O_2)_2(aq) \longrightarrow 2NH_4C_2H_3O_2(aq) + PbBr_2(s)$

Ionic: $2NH_4^+(aq) + 2Br^-(aq) + Pb^{2+}(aq) + 2C_2H_3O_2^-(aq) \longrightarrow 2NH_4^+(aq) + 2C_2H_3O_2^-(aq) + PbBr_2(s)$

Net: $Pb^{2+}(aq) + 2Br^-(aq) \longrightarrow PbBr_2(s)$

(d) Molecular: $2NH_4ClO_4(aq) + Cu(NO_3)_2(aq) \longrightarrow Cu(ClO_4)_2(aq) + 2NH_4NO_3(aq)$

Ionic: $2NH_4^+(aq) + 2ClO_4^-(aq) + Cu^{2+}(aq) + 2NO_3^-(aq) \longrightarrow Cu^{2+}(aq) + 2ClO_4^-(aq) + 2NO_3^-(aq) + 2NH_4^+(aq)$

Net: N.R.

5.79 There are numerous possible answers. One of many possible sets of answers would be:

(a) $NaHCO_3(aq) + HCl(aq) \longrightarrow NaCl(aq) + CO_2(g) + H_2O$

(b) $FeCl_2(aq) + 2NaOH(aq) \longrightarrow Fe(OH)_2(s) + 2NaCl(aq)$

(c) $Ba(NO_3)_2(aq) + K_2SO_3(aq) \longrightarrow BaSO_3(s) + 2KNO_3(aq)$

(d) $2AgNO_3(aq) + Na_2S(aq) \longrightarrow Ag_2S(s) + 2NaNO_3(aq)$

(e) $ZnO(s) + 2HCl(aq) \longrightarrow ZnCl_2(aq) + H_2O$

5.81 **(a)** 1.00 M NaOH **(b)** 0.577 M $CaCl_2$

5.83 658 mL $NaC_2H_3O_2$

5.85 **(a)** 1.46 g NaCl **(b)** 16.2 g $C_6H_{12}O_6$ **(c)** 6.13 g H_2SO_4

5.87 0.11 M H_2SO_4 **5.89** 300 mL. **5.91** 225 mL water

5.93 **(a)** 0.0147 mol Ca^{2+}, 0.0294 mol Cl^-
(b) 0.0204 mol Al^{3+}, 0.061 mol Cl^-
5.95 **(a)** 0.25 M Cr^{2+}, 0.50 M NO_3^-
(b) 0.10 M Cu^{2+}, 0.10 M SO_4^{2-}
(c) 0.48 M Na^+, 0.16 M PO_4^{3-}
(d) 0.15 M Al^{3+}, 0.22 M SO_4^{2-}
5.97 1.07 g $Al_2(SO_4)_3$ **5.99** 11.9 mL $NiCl_2$ soln, 0.36 g $NiCO_3$
5.101 0.113 *M* KOH
$KOH(aq) + HCl(aq) \longrightarrow KCl(aq) + H_2O$
5.103 0.485 g $Al_2(SO_4)_3$ **5.105** 2.00 mL $FeCl_3$ soln, 0.129 g AgCl
5.107 13.3 mL $AlCl_3$ **5.109** 0.167 *M* Fe^{3+}, 3.67 g Fe_2O_3
5.111 0.114 *M* HCl **5.113** **(a)** 2.67×10^{-3} mol $HC_3H_5O_3$
(b) 0.240 g
5.115 **(a)** 3.56×10^{-3} mol Pb, 0.7386 g Pb, 48.40 % Pb

Chapter 6

Practice Exercises

6.1 Oxygen is reduced since it gains electrons. Sodium is oxidized since it loses electrons.

6.2 Aluminum is oxidized and is, therefore, the reducing agent. Chlorine is reduced and is, therefore, the oxidizing agent.

6.3 Fe_2O_3 is reduced and is, therefore, the oxiding agent. Al is oxidized and is, therefore, the reducing agent.

6.4 +3

6.5 **(a)** Ni +2; Cl –1
(b) Mg +2; Ti +4; O –2
(c) K +1; Cr +6; O –2
(d) H +1; P +5, O –2
(e) V +3; C 0; H +1; O –2
(f) N –3; H +1

6.6 +8/3.

6.7 **(a)** Mo +3; Cl −1
(b) Mo +4; S −2
(c) Mo +6; O −2; Cl −1
(d) Mo +6; P −3

6.8 $KClO_3 + 3HNO_2 \longrightarrow KCl + 3HNO_3$
$KClO_3$ is reduced and HNO_2 is oxidized.

6.9 There is no simple way to tell which chlorines are reduced and which are oxidized in this reaction. One analysis would have the Cl in Cl_2 end up as the Cl in NaCl, while the Cl in $NaClO_2$ ends up as the Cl in ClO_2. In this case Cl_2 is reduced and is the oxidizing agent, while $NaClO_2$ is oxidized and is the reducing agent.

6.10 The product is water, because the oxygen is reduced.

6.11 CH_4 undergoes oxidation and O_2 undergoes reduction. This means that CH_4 is the reducing agent and O_2 is the oxidizing agent.

6.12 The charges are not balanced.

$$2Al(s) + 3Cu^{2+}(aq) \longrightarrow 2Al^{3+}(aq) + 3Cu(s)$$

6.13 $3Sn^{2+} + 16H^+ + 2TcO_4^- \longrightarrow 2Tc^{4+} + 8H_2O + 3Sn^{4+}$
6.14 $4Cu + 2NO_3^- + 10H^+ \longrightarrow 4Cu^{2+} + N_2O + 5H_2O$
6.15 $4C_5H_5N + 29O_2 \longrightarrow 4NO_2 + 20CO_2 + 10H_2O$
6.16 $4OH^- + SO_2 \longrightarrow SO_4^{2-} + 2e^- + 2H_2O$
6.17 $2MnO_4^- + 3C_2O_4^{2-} + 4OH^- \longrightarrow 2MnO_2 + 6CO_3^{2-} + 2H_2O$
6.18 $6Br_2 + 12OH^- \longrightarrow 10Br^- + 2BrO_3^- + 6H_2O$
6.19 $Zn + 2MnO_2 \longrightarrow ZnO + Mn_2O_3$
6.20 $Zn \longrightarrow Zn^{2+} + 2e^-$ $2H^+ + 2e^- \longrightarrow H_2$
6.21 **(a)** Molecular: $Mg(s) + 2HCl(aq) \longrightarrow MgCl_2(aq) + H_2(g)$
Ionic: $Mg(s) + 2H^+(aq) + 2Cl^-(aq) \longrightarrow Mg^{2+}(aq) + 2Cl^-(aq) + H_2(g)$
Net ionic: $Mg(s) + 2H^+(aq) \longrightarrow Mg^{2+}(aq) + H_2(g)$
(b) Molecular: $2Al(s) + 6HCl(aq) \longrightarrow 2AlCl_3(aq) + 3H_2(g)$
Ionic: $2Al(s) + 6H^+(aq) + 6Cl^-(aq) \longrightarrow 2Al^{3+}(aq) + 6Cl^-(aq) + 3H_2(g)$
Net ionic: $2Al(s) + 6H^+(aq) \longrightarrow 2Al^{3+}(aq) + 3H_2(g)$
6.22 $H_2SO_4 + 8HI \longrightarrow H_2S + 4I_2 + 4H_2O$
6.23 $Cu^{2+}(aq) + Mg(s) \longrightarrow Cu(s) + Mg^{2+}(aq)$
6.24 **(a)** $2Al(s) + 3Cu^{2+}(aq) \longrightarrow 2Al^{3+}(aq) + 3Cu(s)$
(b) $Ag(s) + Mg^{2+}(aq) \longrightarrow$ No reaction
6.25 $2C_{20}H_{42}(s) + 21O_2(g) \longrightarrow 40C(s) + 42H_2O(g)$
6.26 $2C_5H_8(g) + 9O_2(g) \longrightarrow 10CO_2(g) + 8H_2O(g)$
6.27 $C_2H_5OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(g)$
6.28 $2Sr(s) + O_2(g) \longrightarrow 2SrO(s)$
6.29 $4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s)$

Review Problems

6.23 The sum of the oxidation numbers should be equal to the total charge:
(a) S^{2-}: –2
(b) SO_2: S +4, O –2
(c) P_4: P 0
(d) PH_3: P –3, H +1

6.25 The sum of the oxidation numbers should be equal to the total charge:
(a) O: −2
Na: +1
Cl: +1
(b) O: −2
Na: +1
Cl: +3
(c) O: −2
Na: +1
Cl: +5
(d) O: −2
Na: +1
Cl: +7

6.27 The sum of the oxidation numbers should be zero:
(a) S: −2
Pb: +2
(b) Cl: −1
Ti: +4
(c) Cs +1
O −1/2 (The Cs can only have an oxidation number of +1 or 0.)
(d) F −1
O +1

6.29 Ti +3; N −3 **6.31** O_3; oxidation number of O is 0

6.33 In the forward direction: **Cl_2 is reduced**. However, in HOCl, chlorine has an oxidation number of +1, so **Cl_2 also is oxidized!** (One atom is reduced, the other is oxidized.) In the reverse direction: Cl^- ion is oxidized: This means **Cl^- is the reducing agent**. **HOCl is the oxidizing agent**.

6.35 **(a)** Substance reduced (and oxidizing agent): HNO_3
Substance oxidized (and reducing agent): H_3AsO_3
(b) Substance reduced (and oxidizing agent): HOCl
Substance oxidized (and reducing agent): NaI
(c) Substance reduced (and oxidizing agent): $KMnO_4$
Substance oxidized (and reducing agent): $H_2C_2O_4$
(d) Substance reduced (and oxidizing agent): H_2SO_4
Substance oxidized (and reducing agent): Al

6.37 **(a)** $OCl^- + 2S_2O_3^{2-} + 2H^+ \longrightarrow S_4O_6^{2-} + Cl^- + H_2O$
(b) $2NO_3^- + Cu + 4H^+ \longrightarrow 2NO_2 + Cu^{2+} + 2H_2O$
(c) $3H_3AsO_3 + IO_3^- \longrightarrow I^- + 3H_3AsO_4$
(d) $Zn + SO_4^{2-} + 4H^+ \longrightarrow Zn^{2+} + SO_2 + 2H_2O$
(e) $NO_3^- + 4Zn + 10H^+ \longrightarrow 4Zn^{2+} + NH_4^+ + 3H_2O$
(f) $2Cr^{3+} + 3BiO_3^- + 4H^+ \longrightarrow Cr_2O_7^{2-} + 3Bi^{3+} + 2H_2O$
(g) $I_2 + 5OCl^- + H_2O \longrightarrow 2IO_3^- + 5Cl^- + 2H^+$
(h) $2Mn^{2+} + 5BiO_3^- + 14H^+ \longrightarrow 2MnO_4^- + 5Bi^{3+} + 7H_2O$
(i) $3H_3AsO_3 + Cr_2O_7^{2-} + 8H^+ \longrightarrow 3H_3AsO_4 + 2Cr^{3+} + 4H_2O$

6.39 **(a)** $2CrO_4^{2-} + 3S^{2-} + 4H_2O \longrightarrow 2CrO_2^- + 3S + 8OH^-$
(b) $3C_2O_4^{2-} + 2MnO_4^- + 4H_2O \longrightarrow 6CO_2 + 2MnO_2 + 8OH^-$
(c) $4ClO_3^- + 3N_2H_4 \longrightarrow 4Cl^- + 6NO + 6H_2O$
(d) $NiO_2 + 2Mn(OH)_2 \longrightarrow Ni(OH)_2 + Mn_2O_3 + H_2O$
(e) $3SO_3^{2-} + 2MnO_4^- + H_2O \longrightarrow 3SO_4^{2-} + 2MnO_2 + 2OH^-$

6.41 $10H^+(aq) + NO_3^-(aq) + 4Mg(s) \longrightarrow NH_4^+(aq) + 4Mg^{2+}(aq) + 3H_2O$

6.43 $4OCl^- + S_2O_3^{2-} + H_2O \longrightarrow 4Cl^- + 2SO_4^{2-} + 2H^+$

6.45 $O_3 + Br^- \longrightarrow BrO_3^-$

6.47 **(a)** M: $Mn(s) + 2HCl(aq) \longrightarrow MnCl_2(aq) + H_2(g)$
I: $Mn(s) + 2H^+(aq) + 2Cl^-(aq) \longrightarrow Mn^{2+}(aq) + 2Cl^-(aq) + H_2(g)$
NI: $Mn(s) + 2H^+(aq) \longrightarrow Mn^{2+}(aq) + H_2(g)$
(b) M: $Cd(s) + 2HCl(aq) \longrightarrow CdCl_2(aq) + H_2(g)$
I: $Cd(s) + 2H^+(aq) + 2Cl^-(aq) \longrightarrow Cd^{2+}(aq) + 2Cl^-(aq) + H_2(g)$
NI: $Cd(s) + 2H^+(aq) \longrightarrow Cd^{2+}(aq) + H_2(g)$
(c) M: $Sn(s) + 2HCl(aq) \longrightarrow SnCl_2(aq) + H_2(g)$
I: $Sn(s) + 2H^+(aq) + 2Cl^-(aq) \longrightarrow Sn^{2+}(aq) + 2Cl^-(aq) + H_2(g)$
NI: $Sn(s) + 2H^+(aq) \longrightarrow Sn^{2+}(aq) + H_2(g)$

6.49 **(a)** $3Ag(s) + 4HNO_3(aq) \longrightarrow 3AgNO_3(aq) + 2H_2O + NO(g)$
(b) $Ag(s) + 2HNO_3(aq) \longrightarrow AgNO_3(aq) + H_2O + NO_2(aq)$

6.51 **(a)** N.R.
(b) $2Cr(s) + 3Pb^{2+}(aq) \longrightarrow 2Cr^{3+}(aq) + 3Pb(s)$
(c) $2Ag^+(aq) + Fe(s) \longrightarrow 2Ag(s) + Fe^{2+}(aq)$
(d) $3Ag(s) + Au^{3+}(aq) \longrightarrow Au(s) + 3Ag^+(aq)$

6.53 Increasing ease of oxidation: Pt, Ru, Tl, Pu

6.55 $Cd(s) + 2TlCl(aq) \longrightarrow CdCl_2(aq) + 2Tl(s)$

6.57 $5Mg(s) + 5Zn^{2+}(aq) + 10Cl^{-+}(aq) \longrightarrow 5Mg^{2+}(aq) + 10Cl^-(aq) + 5Zn(s)$

6.59 $10Li(s) + 10H_2O(l) \longrightarrow 5H_2(g) + 10OH^-(aq)$

6.61 **(a)** $2C_6H_6(l) + 15O_2(g) \longrightarrow 12CO_2(g) + 6H_2O(g)$
(b) $2C_4H_{10}(g) + 13O_2(g) \longrightarrow 8CO_2(g) + 10H_2O(g)$
(c) $C_{21}H_{44}(s) + 32O_2(g) \longrightarrow 21CO_2(g) + 22H_2O(g)$

6.63 **(a)** $2C_6H_6(l) + 9O_2(g) \longrightarrow 12CO(g) + 6H_2O(g)$
$2C_4H_{10}(g) + 9O_2(g) \longrightarrow 8CO(g) + 10H_2O(g)$
$2C_{21}H_{44}(s) + 43O_2(g) \longrightarrow 42CO(g) + 44H_2O(g)$
(b) $2C_6H_6(l) + 3O_2(g) \longrightarrow 12C(s) + 6H_2O(g)$
$2C_4H_{10}(g) + 5O_2(g) \longrightarrow 8C(s) + 10H_2O(g)$
$C_{21}H_{44}(s) + 11O_2(g) \longrightarrow 21C(s) + 22H_2O(g)$

6.65 $2CH_3OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 4H_2O(g)$

6.67 $2(CH_3)_2S(g) + 9O_2(g) \longrightarrow 4CO_2(g) + 6H_2O(g) + 2SO_2(g)$

6.69 **(a)** $2Zn(s) + O_2(g) \longrightarrow 2ZnO(s)$
(b) $4Al(s) + 3O_2(g) \longrightarrow 2Al_2O_3(s)$
(c) $2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$
(d) $4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s)$

6.71 **(a)** $IO_3^- + 3SO_3^{2-} \longrightarrow I^- + 3SO_4^{2-}$
(b) 9.55 g Na_2SO_3

6.73 3.53 g Cu

6.75 **(a)** $2MnO_4^- + 5Sn^{2+} + 16H^+ \longrightarrow 2Mn^{2+} + 5Sn^{4+} + 8H_2O$
(b) 17.4 mL $KMnO_4$

6.77 **(a)** 6.38×10^{-3} M I_3^-
(b) 1.01×10^{-3} g SO_2
(c) 2.10×10^{-3}%
(d) 21 ppm

6.79 **(a)** 9.463% **(b)** 18.40%

6.81 **(a)** 0.02994 g H_2O_2 **(b)** 2.994% H_2O_2

6.83 **(a)** $2CrO_4^{2-} + 3SO_3^{2-} + H_2O \longrightarrow 2CrO_2^- + 3SO_4^{2-} + 2OH^-$
(b) 0.875 g Cr in the original alloy
(c) 25.4% Cr

6.85 **(a)** 5.405×10^{-3} mol $C_2O_4^{2-}$ **(b)** 0.5999 g $CaCl_2$
(c) 24.35% $CaCl_2$

$\Delta H° = 1/7(-8876\text{ kJ}) = -1268\text{ kJ}$

7.76 Only **(c)** satisfies this requirement

7.78 **(a)** $2C(s,\text{ graphite}) + 2H_2(g) + O_2(g) \longrightarrow HC_2H_3O_2(l)$
$\Delta H_f° = -487.0\text{ kJ}$
(b) $2C(s,\text{ graphite}) + \frac{1}{2}O_2(g) + 3H_2(g) \longrightarrow C_2H_5OH(l)$
$\Delta H_f° = -277.63\text{ kJ}$
(c) $Ca(s) + \frac{1}{8}S_8(s) + 3O_2(g) + 2H_2(g) \longrightarrow CaSO_4 \cdot 2H_2O(s)$
$\Delta H_f° = -2021.1\text{ kJ}$
(d) $2Na(s) + \frac{1}{8}S_8(s) + 2O_2(g) \longrightarrow Na_2SO_4(s)$
$\Delta H_f° = -1384.5\text{ kJ}$

7.80 **(a)** -196.6 kJ **(b)** -177.8 kJ

7.82 $C_{12}H_{22}O_{11}(s) + 12O_2(g) \longrightarrow 12CO_2(g) + 11H_2O(l)$
$\Delta H_f° = -2.21 \times 10^3\text{ kJ}$

| Chapter 8

Practice Exercises

8.1 5.10×10^{14} Hz **8.2** 2.75×10^{13} Hz **8.3** 3.25 m
8.4 2.63 μm
8.5 656 nm, which is red
8.6 **(a)** 4, 2
(b) 5, 3
(c) 7, 0
Each value of ℓ has a corresponding letter.

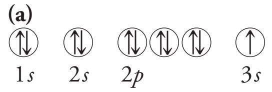
8.7 When $n = 2$, ℓ can be 0, or 1. Thus we have *s*, and *p* subshells. When $n = 5$, ℓ can be 0, 1, 2, 3, or 4. Thus we have *s*, *p*, *d*, *f*, and *g* subshells.
Shell 1: 1 subshell
Shell 2: 2 subshells
Shell 3: 3 subshells
Shell 4: 4 subshells
Shell 5: 5 subshells
Shell 6: 6 subshells

8.8 **(a)** Mg: $1s^22s^22p^63s^2$
(b) Ge: $1s^22s^22p^63s^23p^63d^{10}4s^24p^2$
(c) Cd: $1s^22s^22p^63s^23p^63d^{10}4s^24p^64d^{10}5s^2$
(d) Gd: $1s^22s^22p^63s^23p^63d^{10}4s^24p^64d^{10}4f^75s^25p^65d^16s^2$

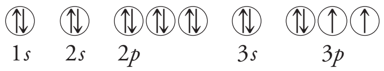
8.9 The electron configuration of an element follows the periodic table. The electrons are filled in the order of the periodic table and the energy levels are determined by the row the element is in and the subshell is given by the column, the first two columns are the *s*-block, the last six columns are the *p*-block, the *d*-block has ten columns, and the *f*-block has 14 columns.

8.10 **(a)** O: $1s^22s^22p^4$
S: $1s^22s^22p^63s^23p^4$
Se: $1s^22s^22p^63s^23p^63d^{10}4s^24p^4$
(b) P: $1s^22s^22p^63s^23p^3$
N: $1s^22s^22p^3$
Sb: $1s^22s^22p^63s^23p^63d^{10}4s^24p^64d^{10}5s^25p^3$
The elements have the same number of electrons in the valence shell, and the only differences between the valence shells are the energy levels.

8.11 **(a)**
Na:



(b)
S:



(c)

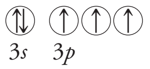
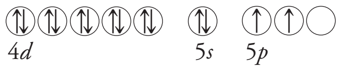
8.12 **(a)** 0 unpaired electrons **(b)** 2 unpaired electrons **(c)** 0 unpaired electrons **(d)** 8 unpaired electrons
8.13 Yes
8.14 **(a)**
P: $[Ne]3s^23p^3$
[Ne]



(3 unpaired electrons)

(b)
Sn: $[Kr]4d^{10}5s^25p^2$
[Kr]



(2 unpaired electrons)

8.15 Based on the definition of valence, there are no examples where more than 8 electrons would occupy the valence shell. For representative elements the valence shell is defined as the occupied shell with the highest value of *n*. In the ground state atom, only *s* and *p* electrons fit this definition. The transition elements have outer electron configurations: $(n\text{-}1)d^n\, ns^m$ so the valence shell is the *ns* subshell.

8.16 **(a)** Se: $4s^24p^4$ **(b)** Sn: $5s^25p^2$ **(c)** I: $5s^25p^5$

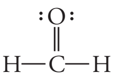
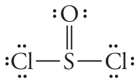
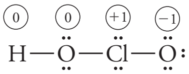
9.96 (a)



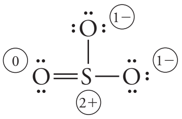
(b)



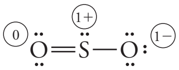
9.98 (a)



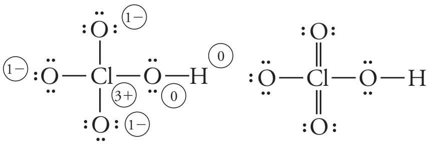
(b)



(c)

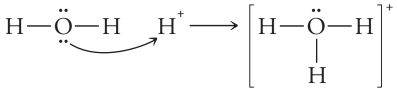


9.100

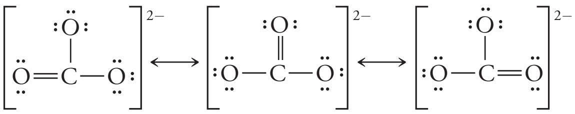


9.102 The formal charges on all of the atoms of the left structure are zero, therefore, the potential energy of this molecule is lower and it is more stable. Group 2 atoms normally have only two bonds.

9.104



9.106 The average bond order is 4/3



9.108

N—O bonds in NO_2^- should be shorter than that in NO_3^-.

9.110

These are not preferred structures, because in each Lewis diagram, one oxygen bears a formal charge of +1 whereas the other bears a formal charge of –1.

Chapter 10

Practice Exercises

10.1 Octahedral

10.2 Trigonal bipyramidal

10.3 Linear

10.4 Linear

10.5 Square planar

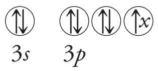
10.6 In SO_3^{2-} trigonal pyramidal
$PbCl_4$ tetrahedral
XeO_4 tetrahedral
OF_2 bent

10.7 Polar

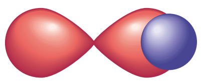
10.8 (a) Non-polar. **(b)** polar. **(c)** polar. **(d)** polar. **(e)** polar.

10.9 The H–Cl bond is formed by the overlap of the half-filled 1*s* atomic orbital of a H atom with the half-filled 3*p* valence orbital of a Cl atom:

Cl atom in HCl (x = H electron):

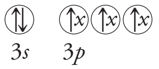


The overlap that gives rise to the H–Cl bond is that of a 1*s* orbital of H with a 3*p* orbital of Cl:

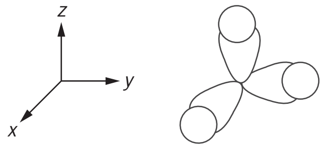


10.10 The half-filled 1*s* atomic orbital of each H atom overlaps with a half-filled 3*p* atomic orbital of the P atom, to give three P–H

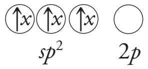
bonds. This should give a bond angle of 90°.
P atom in PH_3 (x = H electron):



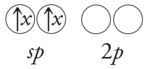
The orbital overlap that forms the P–H bond combines a 1*s* orbital of hydrogen with a 3*p* orbital of phosphorus. (Note: only half of each p orbital is shown):



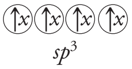
10.11 sp^2 hybrid orbitals on the B, x = Cl electron



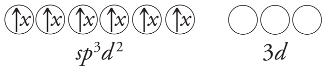
10.12 *sp* hybrid orbitals on the Be; x = F electron



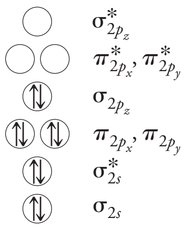
10.13 sp^3



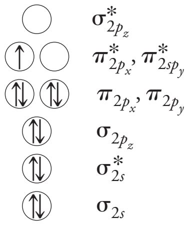
10.14 Since there are five bonding pairs of electrons on the central phosphorous atom, we choose sp^3d hybridization for the P atom. Each of phosphorous's five sp^3d hybrid orbitals overlaps with a 3*p* atomic orbital of a chlorine atom to form a total of five P–Cl single bonds. Four of the 3*d* atomic orbitals of P remain unhybridized.
10.15 Trigonal bipyramidal, sp^3d—*p* bonds
10.16 sp^3d^2
10.17 **(a)** sp^3 **(b)** sp^3d
10.18 NH_3 is sp^3 hybridized. Three of the electron pairs are used for bonding with the three hydrogens. The fourth pair of electrons is a lone pair of electrons. This pair of electrons is used for the formation of the bond between the nitrogen of NH_3 and the hydrogen ion, H^+.
10.19 Octahderal, sp^3d^2
P atom in PCl_6^- (x = Cl electron):



10.20 Atom 1: sp^2 atom 2: sp^3 atom 3: sp^2
There are 10 σ bonds and 2 π bonds in the molecule.
10.21 Atom 1: *sp* atom 2: sp^2 atom 3: sp^3
There are 9 σ bonds and 3 π bonds in the molecule.
10.22 The bond order is 3 and this does agree with the Lewis structure.



10.23



The bond order is 5/2

12.21 A molecular solid

Review Problems

12.83 Diethyl ether
12.85 **(a)** London forces, dipole–dipole and hydrogen bonding
(b) London forces, dipole–dipole
(c) London forces
(d) London forces, dipole–dipole
12.87 Chloroform would be expected to display larger dipole-dipole attractions because it has a larger dipole moment than bromoform. On the other hand, bromoform would be expected to show stronger London forces due to having larger electron clouds, which are more polarizable than those of chlorine.

Since bromoform in fact has a higher boiling point that chloroform, we must conclude that it experiences stronger intermolecular attractions than chloroform, which can only be due to London forces. Therefore, London forces are more important in determining the boiling points of these two compounds.
12.89 London forces are higher in chains than in branched isomers. Therefore, octane has higher London forces between molecules than 2,2,3,3-tetramethylbutane so octane would be more viscous.
12.91 Ethanol
12.93 Ether < acetone < benzene < water < acetic acid
12.95

Compound	Intermolecular forces broken

Chapter 13

Practice Exercises

13.1 3.7 g L^{-1}, Hydrogen sulfide is more soluble in water than nitrogen and oxygen. Hydrogen sulfide reacts with the water to form hydronium ions and HS^-.
13.2 1.12 mg O_2, 1.85 mg N_2 mL
13.3 405.7 mL water
13.4 0.250 g of NaBr, 24.75 g H_2O, 25.0 mL H_2O
13.5 2.0×10^1 g
13.6 1.239 m, smaller
13.7 g CH_3OH for 0.050 m = 0.320 g
g CH_3OH for 0.100 m = 0.640 g
g CH_3OH for 0.150 m = 0.960 g
g CH_3OH for 0.200 m = 1.28 g
g CH_3OH for 0.250 m = 1.60 g
13.8 **(a)** 28.3 g **(b)** 70.7 g **(c)** 1.41 g
13.9 27 m
13.10 16.1 m
13.11 6.82 M
13.12 0.00469 M, $Al(NO_3)_3$, 0.00470 m $Al(NO_3)_3$
13.13 4.90×10^2 torr
13.14 34.5 g stearic acid
13.15 55.4 torr
13.16 45.1 torr
13.17 89.5% to 91.2%
13.18 213 g glucose
13.19 157 g mol^{-1}
13.20 125 g mol^{-1}
13.21 3.68 mm Hg, 50.0 mm H_2O
13.22 222 torr, B. P. = 100.006 °C, M. P. = −0.021 °C note that the significant figure rules were not used for the boiling points
13.23 5.00×10^3 g mol^{-1}
13.24 5.38×10^2 g mol^{-1}
13.25 −0.882 °C, −0.441 °C
13.26 **(a)** −0.372 °C **(b)** −0.0372 °C **(c)** −0.00372 °C

The first freezing point depression, solution **(a)**, could be estimated using a laboratory thermometer that can measure 1 °C increments.

Review Problems

13.42 $KCl(s) \longrightarrow K^+(g) + Cl^-(g)$, $\Delta H° = +715$ kJ mol^{-1}
$K^+(g) + Cl^-(g) \longrightarrow K^+(aq) + Cl^-(aq)$, $\Delta H° = -686$ kJ mol^{-1}
$KCl(s) \longrightarrow K^+(aq) + Cl^-(aq)$, $\Delta H° = +29$ kJ mol^{-1}
13.44 0.038 g/L
13.46 0.020 g L^{-1}

13.50 0.133 m, 2.39×10^{-3}, 2.34%
13.52 5.45%
13.54 7.89%, 4.76 m
13.56 0.359 M $NaNO_3$, 3.00 %, 6.49×10^{-3}
13.58 22.8 torr
13.60 52.7 torr
13.62 70 mol% toluene and 30 mol% benzene
13.64 **(a)** 0.029 **(b)** 2.99×10^{-2} moles **(c)** 278 g/mol
13.66 68.9 g
13.68 240 g/mol
13.70 127 g/mol, $C_8H_4N_2$.
13.72 **(a)** If the equation is correct, the units on both sides of the equation should be g/mol. The units on the right side of this equation are:

$$\frac{(\text{g}) \times (\cancel{\text{L}}\ \cancel{\text{atm}}\ \text{mol}^{-1}\ \cancel{\text{K}^{-1}}) \times (\cancel{\text{K}})}{\cancel{\text{L}} \times \cancel{\text{atm}}} = \text{g/mol}$$

which is correct.
(b) 1.8×10^6 g/mol
13.74 15.3 torr
13.76 1.3×10^4 torr
13.78 −1.1 °C
13.80 2
13.82 1.89

Chapter 14

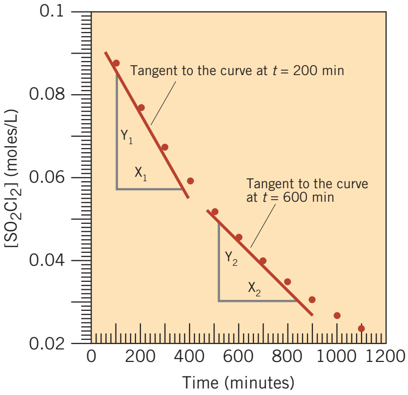
Practice Exercises

14.1 Rate of production of I^- = 8.0×10^{-5} mol L^{-1} s^{-1}. Rate of production of SO_4^{2-} = 2.4×10^{-4} mol L^{-1} s^{-1}.
14.2 Rate of disappearance of O_2 = 0.45 mol L^{-1} s^{-1}. Rate of disappearance of H_2S = 0.30 mol L^{-1} s^{-1}.
14.3 -2.1×10^{-4} mol L^{-1} s^{-1}
14.4 A value near 1×10^{-4} mol L^{-1} s^{-1} is correct.
14.5 **(a)** 9.8×10^{14} L^2 mol^{-2} s^{-1} **(b)** L^2 mol^{-2} s^{-1}
14.6 **(a)** 8.0×10^{-2} L mol^{-1} s^{-1} **(b)** L mol^{-1} s^{-1}
14.7 Order of the reaction with respect to $[BrO_3^-] = 1$
Order of the reaction with respect to $[SO_3^{2-}] = 1$
Overall order of the reaction = 1 + 1 = 2
14.8 Rate = $k[Cl_2]^2[NO]$
14.9 The order with respect to Br_2 is 1, the order with respect to HCO_2H is zero. The overall order of the reaction is 1.
14.10 2.0×10^2 L^2 mol^{-2} s^{-1}. Each of the other data sets also gives the same value.
14.11 **(a)** The rate will increase nine-fold.
(b) The rate will increase three-fold.
(c) The rate will decrease by three fourths.
14.12 **(a)** Rate = $k[NO]^2[H_2]^1$
(b) 2.1×10^5 L^2 mol^{-2} s^{-1}
(c) L^2 mol^{-2} s^{-1}

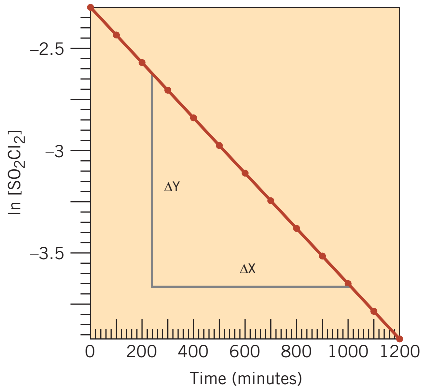
14.13 **(a)** First order with respect to sucrose
(b) $6.17 \times 10^{-4}\ s^{-1}$
14.14 **(a)** Rate $= k[A]^2[B]^2$ **(b)** $6.9 \times 10^{-3}\ L^3\ mol^{-3}\ s^{-1}$
(c) $L^3\ mol^{-3}\ s^{-1}$ **(d)** 4
14.15 $2.56 \times 10^{-2}\ yr^{-1}$
14.16 **(a)** $4.71 \times 10^{-3}\ M$ **(b)** 7.8 min
14.17 18.7 min, 37.4 min
14.18 27.1 yr
14.19 5.41%
14.20 1.90×10^{4} yrs
14.21 The upper limit of dates is 24,800 years and the lower limit of dates is 424 years.
14.22 63 min
14.23 $4.0 \times 10^{-4}\ M$
14.24 $k = 1.03\ L\ mol^{-1}\ s^{-1}\ t_{1/2} = 1.48 \times 10^{3}\ s$
14.25 The reaction is first-order
14.26 322 K or 49 °C
14.27 **(a)** 1.4×10^{2} kJ/mol **(b)** $0.40\ L\ mol^{-1}\ s^{-1}$
14.28 684 K
14.29 **(a)**, **(b)**, and **(e)** may be elementary processes.
Equations **(c)**, **(d)**, and **(f)** are not elementary processes because they have more than two molecules colliding at one time, and this is very unlikely.
14.30 Rate $= k[NO][O_3]$
14.31 Rate $= \dfrac{k[NO_2Cl]^2}{[NO_2]}$

Review Problems

14.46



At 200 min: $1 \times 10^{-4}\ M$/min. At 600 min: $7 \times 10^{-5}\ M$/min.
14.48 The rate of disappearance of hydrogen is three times the rate of disappearance of nitrogen. NH_3 appears twice as fast as N_2 disappears.
14.50 **(a)** Rate for $O_2 = 11.4\ mol\ L^{-1}\ s^{-1}$
(b) Rate for $CO_2 = 7.20\ mol\ L^{-1}\ s^{-1}$
(c) Rate for $H_2O = 8.40\ mol\ L^{-1}\ s^{-1}$
14.52 **(a)** $-\dfrac{d}{dt}[CH_3Cl] = -\dfrac{1}{3}\dfrac{d}{dt}[Cl_2] = \dfrac{d}{dt}[CCl_4] = \dfrac{1}{3}\dfrac{d}{dt}[HCl]$
(b) $9.7 \times 10^{-3}\ M\ s^{-1}$
14.54 $8.0 \times 10^{-11}\ mol\ L^{-1}\ s^{-1}$
14.56 $2.4 \times 10^{2}\ mol\ L^{-1}\ s^{-1}$
14.58 $6.4 \times 10^{2}\ M\ s^{-1}$
14.60 Rate $= k[M][N]^2$, $2.5 \times 10^{3}\ L^2\ mol^{-2}\ s^{-1}$
14.62 Rate $= k[OCl^-][I^-]$, $6.8 \times 10^{9}\ L\ mol^{-1}\ s^{-1}$
14.64 Rate $= k[ICl][H_2]$, $1.04 \times 10^{-1}\ L\ mol^{-1}\ s^{-1}$
14.66



$1.32 \times 10^{-3}\ min^{-1}$
47.68 **(a)** $3.7 \times 10^{-3}\ M$ **(b)** $6.0 \times 10^{-4}\ M$
47.70 $1.85 \times 10^{-2}\ min^{-1}$
14.72 $4.26 \times 10^{-3}\ min^{-1}$
14.74 1.3×10^{4} min
14.76 11 mg/kg
14.78 1/256
14.80 Approximately 500 min.The reaction is first-order in SO_2Cl_2.
14.82 33.2 hr
14.84 1.3×10^{9} years old
14.86 4.0×10^{-13}
14.88 The slope is: -9.5×10^{3} K , $E_a = 79$ kJ/mol
Using the equation $E_a = 79.3$ kJ/mol
14.90 $E_a = 99$ kJ/mol, $A = 6.6 \times 10^{9}\ mol^{-1}\ s^{-1}$, $k = 7.9 \times 10^{-2}\ L\ mol^{-1}\ s^{-1}$
14.92 **(a)** $3.8 \times 10^{-5}\ s^{-1}$ **(b)** $1.6 \times 10^{1}\ s^{-1}$
14.94 Rate $= k\,[AB][C]$
14.96 The intermediate in this reaction is N_2O_2
The overall reaction is:
$2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g)$
Rate $= k[NO]^2[O_2]$

Chapter 15

Practice Exercises

15.1 $2N_2O_3 + O_2 \rightleftharpoons 4NO_2$
15.2

(a) $\dfrac{[H_2O]^2}{[H_2]^2[O_2]} = K_c$ **(b)** $\dfrac{[CO_2][H_2O]^2}{[CH_4][O_2]^2} = K_c$

15.3 1.2×10^{-13}
15.4 1.9×10^{5}
15.5 $K_P = \dfrac{(P_{N_2O})^2}{(P_{N_2})^2(P_{O_2})}$
15.6 $K_P = \dfrac{(P_{HI})^2}{(P_{H_2})^2(P_{I_2})}$
15.7 1.8×10^{36}
15.8 K_p is smaller than K_c. $K_c = 57$
15.9 $K_c = \dfrac{1}{[NH_3(g)][HCl(g)]}$
15.10
(a) $K_c = \dfrac{1}{[Cl_2(g)]}$
(b) $K_c = [Na^+(aq)][OH^-(aq)][H_2(g)]$

(c) $K_c = [Ag^+]^2[CrO_4^{2-}]$

(d) $K_c = \dfrac{[Ca^{+2}(aq)][HCO_3^-(aq)]^2}{[CO_2(aq)]}$

15.11 The reaction will move to the left.

15.12 (a), **(c)**, **(b)**

15.13 There will be no change in the amount of H_3PO_4.

15.14 (a) Decreasing the concentration of Cl_2 at equilibrium, the value of K_p will be unchanged.

(b) Increasing the amount of Cl_2 at equilibrium, the value of K_p will be unchanged.

(c) Increasing the amount of Cl_2 at equilibrium, decreasing the value of K_p.

(d) Decreasing the concentration of Cl_2 at equilibrium, the value of K_p will be unchanged.

15.15 [CO] decreases by 0.060 mol/L and $[CO_2]$ increases by 0.060 mol/L

15.16 $K_c = 4.06$

15.17 (a) $[PCl_3] = 0.200\ M$
$[Cl_2] = 0.100\ M$
$[PCl_5] = 0.000\ M$

(b) The change in concentration of PCl_3 was (0.200 – 0.120) $M = 0.080$ mol/L. The Cl_2 has decreased by 0.080 M and PCl_5 has increased by 0.080 M.

(c) $[PCl_3] = 0.120\ M$, $[PCl_5] = 0.080\ M$, $[Cl_2] = 0.020\ M$.

(d) $K_c = 33$

15.18 $[NO_2] = 1.04 \times 10^{-2}\ M$

15.19 $[C_2H_5OH] = 8.98 \times 10^{-3}\ M$

15.20 $[H_2] = [I_2] = 0.044\ M$, $[HI] = 0.312\ M$.

15.21 $[H_2] = 0.107\ M$
$[I_2] = 0.0066\ M$
$[HI] = 0.1868\ M$.

15.22 $[N_2] = 6.2 \times 10^{-4}$
$[H_2] = 1.9 \times 10^{-3}$

15.23 $[NO] = 1.1 \times 10^{-17}\ M$

Review Problems

15.19 (a) $K_c = \dfrac{[POCl_3]^2}{[PCl_3]^2[O_2]}$ **(d)** $K_c = \dfrac{[NO_2]^2[H_2O]^8}{[N_2H_4][H_2O_2]^6}$

(b) $K_c = \dfrac{[SO_2]^2[O_2]}{[SO_3]^2}$ **(e)** $K_c = \dfrac{[SO_2][HCl]^2}{[SOCl_2][H_2O]}$

Chapter 16

Practice Exercises

16.1 Conjugate acid base pairs **(a)**, **(c)**, and **(f)**

(b) The conjugate base of HI is I^-

(d) The conjugate base of HNO_2 is NO_2^- and the conjugate base of NH_4^+ is NH_3

(e) The conjugate acid of CO_3^{2-} is HCO_3^- and the conjugate acid of CN^- is HCN

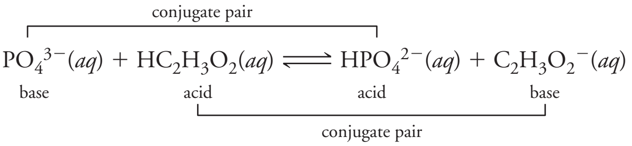
16.2 In each case the conjugate base is obtained by removing a proton from the acid:
(a) OH^- **(b)** I^- **(c)** NO_2^- **(d)** $H_2PO_4^-$
(e) HPO_4^{2-} **(f)** PO_4^{3-} **(g)** HS^- **(h)** NH_3

16.3 In each case the conjugate acid is obtained by adding a proton to the base:
(a) H_2O_2 **(b)** HSO_4^- **(c)** HCO_3^- **(d)** HCN
(e) NH_3 **(f)** NH_4^+ **(g)** H_3PO_4 **(h)** $H_2PO_4^-$

16.4 HCN and CN^- HCl and Cl^-

16.5 The Brønsted acids: $H_2PO_4^-(aq)$ and $H_2CO_3(aq)$
The Brønsted bases: $HCO_3^-(aq)$ and $HPO_4^{2-}(aq)$

16.6



conjugate pair
base
acid
acid
base
conjugate pair

$$PO_4^{3-}(aq) + HC_2H_3O_2(aq) \rightleftharpoons HPO_4^{2-}(aq) + C_2H_3O_2^-(aq)$$

16.7 **(a)** $H_2PO_4^-$ amphoteric, since it can both accept and donate a proton **(b)** HPO_4^{2-} amphoteric, since it can both accept and donate a proton **(c)** H_2S amphoteric, since it can both accept and donate a proton **(d)** H_3PO_4 not amphoteric: it can only donate protons **(e)** NH_4^+ not amphoteric: it can only donate protons **(f)** H_2O amphoteric, since it can both accept and donate a proton **(g)** HI not amphoteric: it can only donate protons **(h)** HNO_2 not amphoteric: it can only donate protons

16.8 $HPO_4^{2-}(aq) + OH^-(aq) \longrightarrow PO_4^{3-}(aq) + H_2O$; HPO_4^{2-} acting as an acid

$HPO_4^{2-}(aq) + H_3O^+(aq) \longrightarrow H_2PO_4^- + H_2O$; HPO_4^{2-} acting as a base

16.9 $HSO_4^-(aq) + HPO_4^{2-}(aq) \longrightarrow SO_4^{-2}(aq) + H_2PO_4^-(aq)$

16.10 The substances on the right because they are the weaker acid and base.

16.11 **(a)** $HF < HBr < HI$
(b) $PH_3 < H_2S < HCl$
(c) $H_2O < H_2Se < H_2Te$
(d) $AsH_3 < H_2Se < HBr$
(e) $PH_3 < H_2Se < HI$

16.12 **(a)** HBr **(b)** H_2Te **(c)** H_2S

16.13 **(a)** $HClO_3$ **(b)** H_2SO_4

16.14 **(a)** H_3AsO_4 **(b)** H_2TeO_4

16.15 **(a)** HIO_4 **(b)** H_2TeO_4 **(c)** H_3AsO_4

16.16 **(a)** H_2SO_4 **(b)** H_3AsO_4

16.17 The acid strength decreases as follows:
$FCH_2COOH > ClCH_2COOH > BrCH_2COOH$

16.18 **(a)** NH_3, Lewis base
H^+, Lewis acid
(b) O^{2-}, Lewis base
SeO_3, Lewis acid
(c) Ag^+, Lewis acid
NH_3, Lewis base

16.19 **(a)** Fluoride ions have a filled octet of electrons and are likely to behave as Lewis bases, i.e., electron pair donors.
(b) $BeCl_2$ is a likely Lewis acid since it has an incomplete shell. The Be atom has only two valence electrons and it can easily accept a pair of electrons.
(c) It could reasonably be considered a potential Lewis base since it contains three oxygens, each with lone pairs and partial negative charges. However, it is more effective as a Lewis acid, since the central sulfur bears a significant positive charge.

19.15 3596 kJ work for $C_2H_5OH(l)$, 5803 kJ for $C_8H_{18}(l)$, C_8H_{18} is a better fuel on a gram basis.
19.16 788 kJ
19.17 $+90.5\ J\ K^{-1}$
19.18 614 K (341 °C)
19.19 The reaction should be spontaneous
19.20 We do not expect to see products formed from reactants.
19.21 −4.3 kJ
19.22 +32.8 kJ, –34.7 kJ, the equilibrium shifts to products
19.23 $\Delta G = 0$ the system is at equilibrium
19.24 The reaction will proceed to the right
19.25 −33 kJ
19.26 0.26
19.27 −260.5 kJ for 1-propanol, −88 kJ for 2-bromobutane
19.28 −117 kJ for C_6H_{12}, +255.6 kJ for C_6H_6

Review Problems

19.46 +1.000 kJ, endothermic
19.48 81 J
19.50 **(a)** $\Delta H° = +\ 24.58$ kJ $\Delta E = 19.6$ kJ
(b) $\Delta H° = -178$ kJ $\Delta E = -175$ kJ
(c) $\Delta H° = 847.6$ kJ $\Delta E = \Delta H°$
(d) $\Delta H° = 65.029$ kJ $\Delta E = \Delta H°$
19.52 $\Delta E = -350$ kJ $\Delta E_{217\ °C} = -354$ kJ
19.54 **(a)** $\Delta H° = -178$ kJ, spontaneous **(b)** $\Delta H° = -311$ kJ, spontaneous **(c)** $\Delta H° = +1084.3$ kJ, not spontaneous
19.56 **(1)** The number of moles of products and reactants
(2) The state of the products versus reactants
(3) The complexity of the molecules
19.58 **(a)** Negative **(b)** negative **(c)** negative **(d)** positive
19.60 **(a)** –198.3 J/K, not spontaneous **(b)** –332.3 J/K, not spontaneous **(c)** +92.6 J/K, spontaneous **(d)** +14 J/K, spontaneous **(e)** +159 J/K, spontaneous

19.62 **(a)** $-52.8\text{ J mol}^{-1}\text{ K}^{-1}$ **(b)** $-868.9\text{ J mol}^{-1}\text{ K}^{-1}$ **(c)** $-318\text{ J mol}^{-1}\text{ K}^{-1}$
19.64 -269.7 J/K
19.66 -209 kJ/mol
19.68 **(a)** -82.3 kJ **(b)** -8.8 kJ **(c)** $+70.7$ kJ
19.70 $+0.16$ kJ
19.72 -1299.8 kJ
19.74 333 K
19.76 $101\text{ J mol}^{-1}\text{ K}^{-1}$
19.78 Spontaneous
19.80 **(a)** $K_p = 3.63 \times 10^{43}$ **(b)** $K_p = 5.37 \times 10^{-13}$
19.82 The system is not at equilibrium and must shift to the right to reach equilibrium.
19.84 $K_p = 8.000 \times 10^8$
This is a favorable reaction, since the equilibrium lies far to the side favoring products and is worth studying as a method for methane production.
19.86 If $\Delta G° = 0$, $K_c = 1$. If we start with pure products, the value of Q will be infinite (there are zero reactants) and, since $Q > K_c$, the equilibrium will shift toward the reactants, i.e., the pure products will decompose to their reactants.
19.88 1.16×10^3 kJ/mol
19.90 354 kJ/mol
19.92 577.7 kJ/mol
19.94 308.0 kJ/mol
19.96 85 kJ/mol
19.98 The heat of formation of CF_4 should be more exothermic than that of CCl_4 because more energy is released on formation of a C—F bond than on formation of a C—Cl bond. Also, less energy is needed to form gaseous F atoms than to form gaseous Cl atoms.

Chapter 21

Practice Exercises

21.1 45.9 g
21.2 46.5 g
21.3 0.166974 u
21.4 9.965×10^{-12} J/nucleon
21.5 ${}^{226}_{88}\text{Ra} \longrightarrow {}^{222}_{86}\text{Rn} + {}^{4}_{2}\text{He} + {}^{0}_{0}\gamma$ An alpha particle is emitted.
21.6 ${}^{90}_{38}\text{Sr} \longrightarrow {}^{90}_{39}\text{Y} + {}^{0}_{-1}e$
21.7 ${}^{11}_{6}\text{C} \longrightarrow {}^{11}_{5}\text{B} + {}^{0}_{1}e + \nu$
21.8 ${}^{13}_{4}\text{Be} \longrightarrow {}^{12}_{4}\text{Be} + {}^{1}_{0}n$
21.9 ${}^{72}_{34}\text{Se} + {}^{0}_{-1}e \longrightarrow {}^{72}_{33}\text{As} + \text{X ray} + \nu$
21.10 ${}^{242}_{96}\text{Cm} \longrightarrow {}^{238}_{94}\text{Pu} + {}^{4}_{2}\text{He}$
21.11 ${}^{56}_{26}\text{Fe} \longrightarrow {}^{59}_{27}\text{Co} + {}^{0}_{-1}e$
21.12 50.4% Pu
21.13 7.36×10^4 atoms ${}^{222}\text{Rn}$
21.14 20 m
21.15 100 units

Review Problems

21.48 **(a)** 1.01 kg **(b)** 3.91 kg **(c)** 12.3 kg
21.50 1.11×10^{-11} g
21.52 3.18 ng, 1.77×10^{-8}%
21.54 1.8×10^{-13} J per nucleon
21.56 0.5526646 u, 8.2485×10^{-11} J
21.58 **(a)** ${}^{211}_{83}\text{Bi}$ **(b)** ${}^{177}_{72}\text{Hf}$ **(c)** ${}^{216}_{84}\text{Po}$ **(d)** ${}^{19}_{9}\text{F}$
21.60 **(a)** ${}^{242}_{94}\text{Pu} \longrightarrow {}^{4}_{2}\text{He} + {}^{238}_{92}\text{U}$
  (b) ${}^{28}_{12}\text{Mg} \longrightarrow {}^{0}_{-1}e + {}^{28}_{13}\text{Al}$
  (c) ${}^{26}_{14}\text{Si} \longrightarrow {}^{0}_{1}e + {}^{26}_{13}\text{Al}$
  (d) ${}^{37}_{18}\text{Ar} \longrightarrow {}^{0}_{-1}e + {}^{37}_{17}\text{Cl}$
21.62 **(a)** ${}^{261}_{102}\text{No}$ **(b)** ${}^{211}_{82}\text{Pb}$ **(c)** ${}^{141}_{61}\text{Pm}$ **(d)** ${}^{179}_{74}\text{W}$
21.64 ${}^{87}_{36}\text{Kr} \longrightarrow {}^{86}_{36}\text{Kr} + {}^{1}_{0}n$
21.66 The more likely process is positron emission, because this produces a product having a higher neutron-to-proton ratio:
${}^{38}_{19}\text{K} \longrightarrow {}^{0}_{1}e + {}^{38}_{18}\text{Ar}$
21.68 ${}^{209}_{84}\text{Po} \longrightarrow {}^{205}_{82}\text{Pb} + {}^{4}_{2}\text{He}$
21.70 0.0469 mg
21.72 ${}^{53}_{24}\text{Cr}^*$ forms. The reaction is:
${}^{51}_{23}\text{V} + {}^{2}_{1}\text{H} \longrightarrow {}^{53}_{24}\text{Cr}^* \longrightarrow {}^{1}_{1}p + {}^{52}_{23}\text{V}$
21.74 ${}^{80}_{35}\text{Br}$
21.76 ${}^{55}_{26}\text{Fe}$; ${}^{55}_{25}\text{Mn} + {}^{1}_{1}p \longrightarrow {}^{1}_{0}n + {}^{55}_{26}\text{Fe}$
21.78 ${}^{70}_{30}\text{Zn} + {}^{208}_{82}\text{Pb} \longrightarrow {}^{278}_{112}\text{Uub} \longrightarrow {}^{1}_{0}n + {}^{277}_{112}\text{Uub}$
21.80 6.3 m
21.82 6.6 m
21.84 This is one curie. It is also 3.7×10^{10} Bq
21.86 2.4×10^7 Bq, 650 µCi
21.88 6.9×10^5 s
21.90 3.2%
21.92 2.84×10^{-3} Ci/g
21.94 1.3×10^9 years old
21.96 2.7×10^4 yr
21.98 ${}^{235}_{92}\text{U} + {}^{1}_{0}n \longrightarrow {}^{94}_{38}\text{Sr} + {}^{140}_{54}\text{Xe} + 2\,{}^{1}_{0}n$

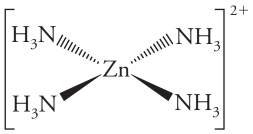
Chapter 22

Practice Exercises

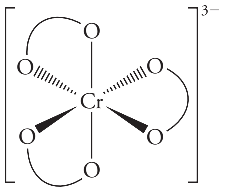
22.1 $[Ag(S_2O_3)_2]^{3-}$ $(NH_4)_3Ag(S_2O_3)_2$
22.2 $AlCl_3 \cdot 6H_2O$ $[Al(H_2O)_6]^{3+}$
22.3 $[CrCl_2(H_2O)_4]^+$ The counter ion would be a halide
22.4 **(a)** $[SnCl_6]^{2-}$
  (b) $(NH_4)_2[Fe(CN)_4(H_2O)_2]$
  (c) $OsBr_2(H_2NCH_2CH_2NH_2)_2$ or $OsBr_2(en)_2$
22.5 **(a)** potassium hexacyanoferrate(III)
  (b) dichlorobis(ethylenediamine)chromium(III) sulfate
  (c) hexaaquacobalt(II) hexafluorochromate(II)
22.6 Six
22.7 **(a)** six **(b)** six **(c)** six
22.8 **(a)** four, square planar **(b)** two, linear

Review Problems

22.40 The net charge is –3, and the formula is $[Fe(CN)_6]^{3-}$, hexacyanoferrate(III) ion
22.42 $[CoCl_2(en)_2]^+$
22.44 **(a)** $C_2O_4{}^{2-}$ oxalato **(b)** S^{2-} sulfido or thio **(c)** Cl^- chloro **(d)** $(CH_3)_2NH$ dimethylamine
22.46 **(a)** hexaamminenickel(II) chloride
  (b) triamminetrichlorochromate(II) ion
  (c) hexanitrocobaltate(III) ion
  (d) diamminetetracyanomanganate(II) ion
  (e) potassium trioxalatoferrate(III) or potassium trisoxalatoferrate(III)
22.48 **(a)** $[Fe(CN)_2(H_2O)_4]^+$
  (b) $[Ni(C_2O_4)(NH_3)_4]$
  (c) $[Al(OH)(H_2O)_5]Cl_2$
  (d) $K_3[Mn(SCN)_6]$
  (e) $[CuCl_4]^{2-}$
22.50 Coordination number is six, oxidation number is +2.
22.52 **(a)**

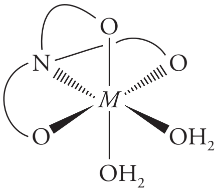


(b)



The curved lines represent the backbone of the oxalate ion.

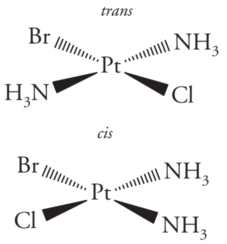
22.54



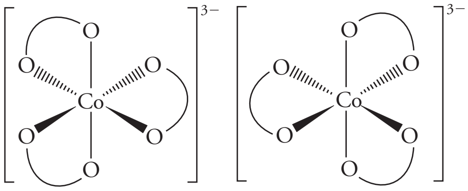
The curved lines represent —CH$_2$—C(=O)— groups.

22.56 Since both are the *cis* isomer, they are identical.

22.58



22.60



22.62 **(a)** $[Cr(H_2O)_6]^{3+}$ **(b)** $[Cr(en)_3]^{3+}$

22.64 $[Cr(CN)_6]^{3-}$

22.66 **(a)** $[RuCl(NH_3)_5]^{3+}$
(b) $[Ru(NH_3)_6]^{3+}$

22.68 CoA_6^{2+}, A produces a larger crystal filed splitting than B, so you are removing a higher energy electron in CoA_6^{2+} than in CoB_6^{2+}.

22.70 High-spin d^7; it cannot be diamagnetic.

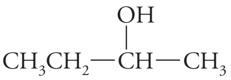
Chapter 23

Practice Exercises

23.1 2,2-dimethylpropane

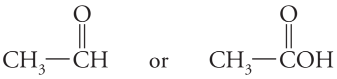
23.2 **(a)** 3-methylhexane
(b) 4-ethyl-2,3-dimethylheptane
(c) 5-ethyl-2,4,6-trimethyloctane

23.3



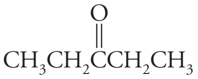
$CH_3CH_2-\overset{OH}{\overset{|}{CH}}-CH_3$

23.4 **(a)**



$CH_3-\overset{O}{\overset{\|}{C}}H$ or $CH_3-\overset{O}{\overset{\|}{C}}OH$

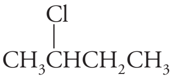
(b)



$CH_3CH_2\overset{O}{\overset{\|}{C}}CH_2CH_3$

(c) Tertiary alcohols do not undergo oxidation in the same manner as primary and secondary alcohols.

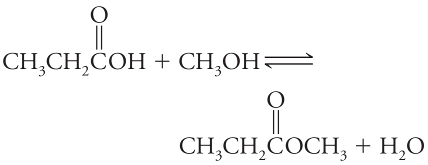
23.5 **(a)**



$CH_3\overset{Cl}{\overset{|}{C}}HCH_2CH_3$

(b) $CH_3CH{=}CH_2$

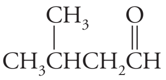
23.6



$CH_3CH_2\overset{O}{\overset{\|}{C}}OH + CH_3OH \rightleftharpoons CH_3CH_2\overset{O}{\overset{\|}{C}}OCH_3 + H_2O$

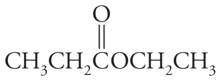
methylpropanoate

23.7 **(a)**



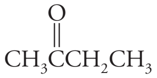
$CH_3\overset{CH_3}{\overset{|}{C}}HCH_2\overset{O}{\overset{\|}{C}}H$

(b)



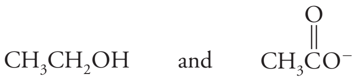
$CH_3CH_2\overset{O}{\overset{\|}{C}}OCH_2CH_3$

(c)



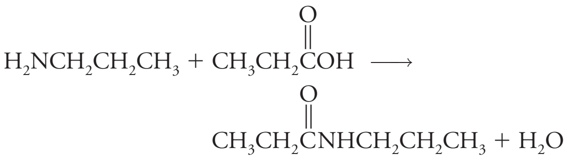
$CH_3\overset{O}{\overset{\|}{C}}CH_2CH_3$

23.8



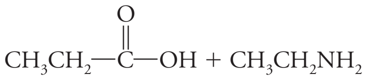
CH_3CH_2OH and $CH_3\overset{O}{\overset{\|}{C}}O^-$

23.9



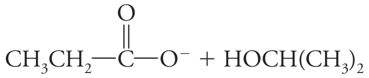
$H_2NCH_2CH_2CH_3 + CH_3CH_2\overset{O}{\overset{\|}{C}}OH \longrightarrow CH_3CH_2\overset{O}{\overset{\|}{C}}NHCH_2CH_2CH_3 + H_2O$

23.10 **(a)**



$CH_3CH_2-\overset{O}{\overset{\|}{C}}-OH + CH_3CH_2NH_2$

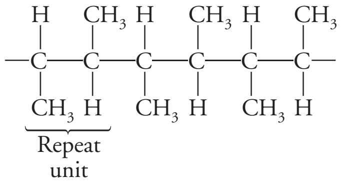
(b)



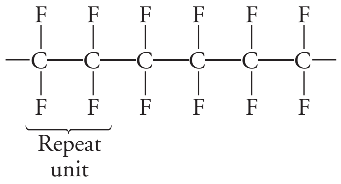
$CH_3CH_2-\overset{O}{\overset{\|}{C}}-O^- + HOCH(CH_3)_2$

(c) $CH_3CH_2CH{=}CH_2$

23.11

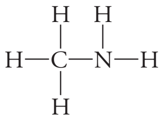


23.12



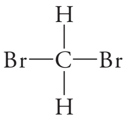
Review Problems

23.91 **(a)**



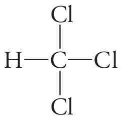
$H-\overset{H}{\underset{H}{\overset{|}{\underset{|}{C}}}}-\overset{H}{\overset{|}{N}}-H$

(b)



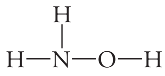
$Br-\overset{H}{\underset{H}{\overset{|}{\underset{|}{C}}}}-Br$

(c)



$H-\overset{Cl}{\underset{Cl}{\overset{|}{\underset{|}{C}}}}-Cl$

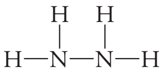
(d)



$H-\overset{H}{\overset{|}{N}}-O-H$

(e) $H-C\equiv C-H$

(f)



$H-\overset{H}{\overset{|}{N}}-\overset{H}{\overset{|}{N}}-H$

23.93 **(a)** alkene **(d)** carboxylic acid
(b) alcohol **(e)** amine
(c) ester **(f)** alcohol

23.95 b, e, and f

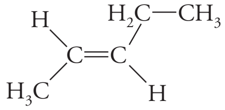
23.97 **(a)** amine **(b)** amine **(c)** amide **(d)** amine, ketone

23.99 **(a)** Identical **(b)** identical **(c)** unrelated
(d) isomers **(e)** identical **(f)** identical
(g) isomers

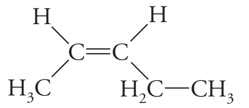
23.101 **(a)** pentane **(b)** 2-methylpentane **(c)** 2,4-dimethylhexane

23.103 (a) No isomers

(b)

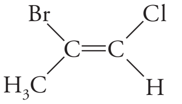


trans

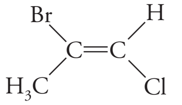


cis

(c)



cis

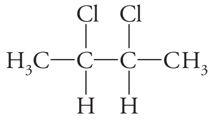


trans

23.105 (a) CH_3CH_3 **(b)** $ClCH_2CH_2Cl$ **(c)** $BrCH_2CH_2Br$
(d) CH_3CH_2Cl **(e)** CH_3CH_2Br **(f)** CH_3CH_2OH

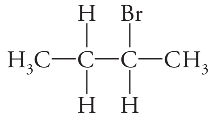
23.107 (a) $CH_3CH_2CH_2CH_3$

(b)



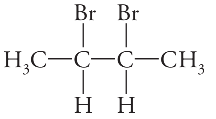
$H_3C-\underset{H}{\overset{Cl}{C}}-\underset{H}{\overset{Cl}{C}}-CH_3$

(e)



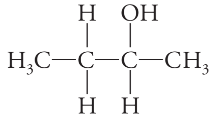
$H_3C-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{Br}{C}}-CH_3$

(c)



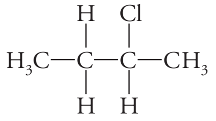
$H_3C-\underset{H}{\overset{Br}{C}}-\underset{H}{\overset{Br}{C}}-CH_3$

(f)



$H_3C-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{OH}{C}}-CH_3$

(d)



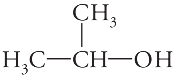
$H_3C-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{Cl}{C}}-CH_3$

23.109 This sort of reaction would disrupt the π delocalization of the benzene ring. The subsequent loss of resonance energy would not be favorable.

23.111

CH_3OH	IUPAC name = methanol;	common name = methyl alcohol
CH_3CH_2OH	IUPAC name = ethanol;	common name = ethyl alcohol
$CH_3CH_2CH_2OH$	IUPAC name = 1-propanol;	common name = propyl alcohol

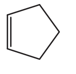
$(CH_3)_2COH$ or as shown below



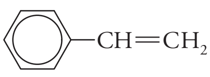
$H_3C-\overset{CH_3}{\overset{|}{C}H}-OH$ IUPAC name = 2-propanol; common name = isopropyl alcohol

23.113 $CH_3CH_2CH_2-O-CH_3$ methyl propyl ether
$CH_3CH_2-O-CH_2CH_3$ diethyl ether
$(CH_3)_2CH-O-CH_3$ methyl 2-propyl ether

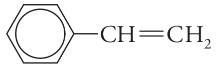
23.115 (a)



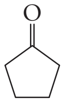
(b)



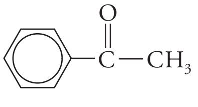
(c)



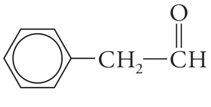
23.117 (a)



(b)



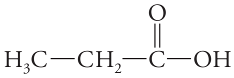
(c)



23.119 The elimination of water can result in a C═C double bond in two locations:

$CH_2═CHCH_2CH_3$	$CH_3CH═CHCH_3$
1-butene	2-butene

23.121 The aldehyde is more easily oxidized. The product is:

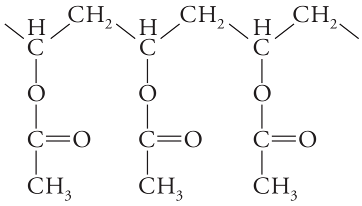


$H_3C-CH_2-\overset{O}{\overset{\|}{C}}-OH$

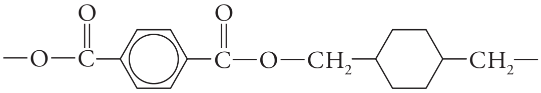
23.123 (a) $CH_3CH_2CO_2H$
(b) $CH_3CH_2CO_2H + CH_3OH$
(c) $Na^+ + CH_3CH_2CH_2CO_2^- + H_2O$

23.125 $CH_3CO_2H + CH_3CH_2NHCH_2CH_3$

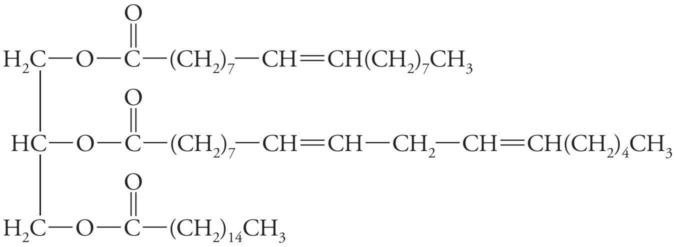
23.127



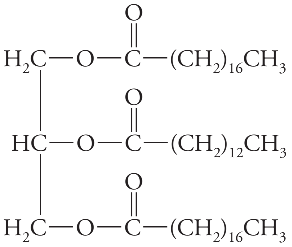
23.129



23.131

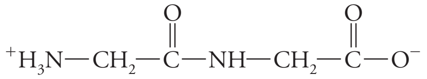


23.133



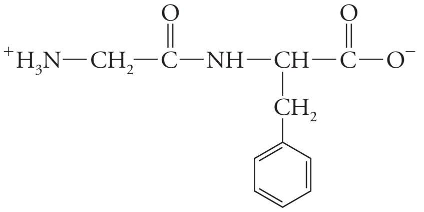
23.135 Hydrophobic sites are composed of fatty acid units. Hydrophilic sites are composed of charged units.

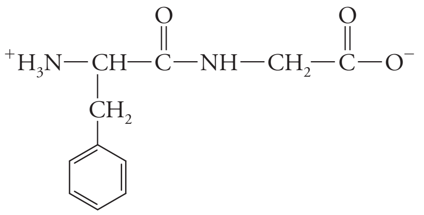
23.137



$^{+}H_3N-CH_2-\overset{O}{\overset{\|}{C}}-NH-CH_2-\overset{O}{\overset{\|}{C}}-O^{-}$

23.139





Appendix C

Tables of Selected Data

Table C.1 **Electron Configurations of the Elements**

Atomic Number			Atomic Number			Atomic Number		
1	H	$1s^1$	41	Nb	[Kr] $5s^1\ 4d^4$	81	Tl	[Xe] $6s^2\ 4f^{14}\ 5d^{10}\ 6p^1$

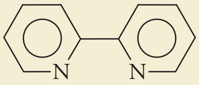
$BaHPO_4$	4.0×10^{-8}
$LaPO_4$	3.7×10^{-23}
$Fe_3(PO_4)_2$	1×10^{-36}
Ag_3PO_4	8.9×10^{-17}
$FePO_4$	9.9×10^{-16}
$Zn_3(PO_4)_2$	5×10^{-36}
$Pb_3(PO_4)_2$	3.0×10^{-44}
$Ba_3(PO_4)_2$	5.8×10^{-38}
Ferrocyanides	
$Zn_2[Fe(CN)_6]$	2.1×10^{-16}
$Cd_2[Fe(CN)_6]$	4.2×10^{-18}
$Pb_2[Fe(CN)_6]$	9.5×10^{-19}

Table C.7 Formation Constants of Complexes (25 °C)

Complex Ion Equilibrium	K_{form}
Halide Complexes	
$Al^{3+} + 6F^- \rightleftharpoons [AlF_6]^{3-}$	1×10^{20}
$Al^{3+} + 4F^- \rightleftharpoons [AlF_4]^-$	2.0×10^{8}
$Be^{2+} + 4F^- \rightleftharpoons [BeF_4]^{2-}$	1.3×10^{13}
$Sn^{4+} + 6F^- \rightleftharpoons [SnF_6]^{2-}$	1×10^{25}
$Cu^+ + 2Cl^- \rightleftharpoons [CuCl_2]^-$	3×10^{5}
$Ag^+ + 2Cl^- \rightleftharpoons [AgCl_2]^-$	1.8×10^{5}
$Pb^{2+} + 4Cl^- \rightleftharpoons [PbCl_4]^{2-}$	2.5×10^{15}
$Zn^{2+} + 4Cl^- \rightleftharpoons [ZnCl_4]^{2-}$	1.6
$Hg^{2+} + 4Cl^- \rightleftharpoons [HgCl_4]^{2-}$	5.0×10^{15}
$Cu^+ + 2Br^- \rightleftharpoons [CuBr_2]^-$	8×10^{5}
$Ag^+ + 2Br^- \rightleftharpoons [AgBr_2]^-$	1.7×10^{7}
$Hg^{2+} + 4Br^- \rightleftharpoons [HgBr_4]^{2-}$	1×10^{21}
$Cu^+ + 2I^- \rightleftharpoons [CuI_2]^-$	8×10^{8}
$Ag^+ + 2I^- \rightleftharpoons [AgI_2]^-$	1×10^{11}
$Pb^{2+} + 4I^- \rightleftharpoons [PbI_4]^{2-}$	3×10^{4}
$Hg^{2+} + 4I^- \rightleftharpoons [HgI_4]^{2-}$	1.9×10^{30}
Ammonia Complexes	
$Ag^+ + 2NH_3 \rightleftharpoons [Ag(NH_3)_2]^+$	1.6×10^{7}
$Zn^{2+} + 4NH_3 \rightleftharpoons [Zn(NH_3)_4]^{2+}$	7.8×10^{8}
$Cu^{2+} + 4NH_3 \rightleftharpoons [Cu(NH_3)_4]^{2+}$	1.1×10^{13}
$Hg^{2+} + 4NH_3 \rightleftharpoons [Hg(NH_3)_4]^{2+}$	1.8×10^{19}
$Co^{2+} + 6NH_3 \rightleftharpoons [Co(NH_3)_6]^{2+}$	5.0×10^{4}
$Co^{3+} + 6NH_3 \rightleftharpoons [Co(NH_3)_6]^{3+}$	4.6×10^{33}
$Cd^{2+} + 6NH_3 \rightleftharpoons [Cd(NH_3)_6]^{2+}$	2.6×10^{5}
$Ni^{2+} + 6NH_3 \rightleftharpoons [Ni(NH_3)_6]^{2+}$	2.0×10^{8}
Cyanide Complexes	
$Fe^{2+} + 6CN^- \rightleftharpoons [Fe(CN)_6]^{4-}$	1.0×10^{24}
$Fe^{3+} + 6CN^- \rightleftharpoons [Fe(CN)_6]^{3-}$	1.0×10^{31}
$Ag^+ + 2CN^- \rightleftharpoons [Ag(CN)_2]^-$	5.3×10^{18}
$Cu^+ + 2CN^- \rightleftharpoons [Cu(CN)_2]^-$	1.0×10^{16}
$Cd^{2+} + 4CN^- \rightleftharpoons [Cd(CN)_4]^{2-}$	7.7×10^{16}
$Au^+ + 2CN^- \rightleftharpoons [Au(CN)_2]^-$	2×10^{38}
Complexes with Other Monodentate Ligands	
Methylamine (CH_3NH_2)	
$Ag^+ + 2CH_3NH_2 \rightleftharpoons [Ag(CH_3NH_2)_2]^+$	7.8×10^{6}
Thiocyanate Ion (SCN^-)	
$Cd^{2+} + 4SCN^- \rightleftharpoons [Cd(SCN)_4]^{2-}$	1×10^{3}
$Cu^{2+} + 2SCN^- \rightleftharpoons [Cu(SCN)_2]$	5.6×10^{3}
$Fe^{3+} + 3SCN^- \rightleftharpoons [Fe(SCN)_3]$	2×10^{6}
$Hg^{2+} + 4SCN^- \rightleftharpoons [Hg(SCN)_4]^{2-}$	5.0×10^{21}
Hydroxide Ion (OH^-)	
$Cu^{2+} + 4OH^- \rightleftharpoons [Cu(OH)_4]^{2-}$	1.3×10^{16}
$Zn^{2+} + 4OH^- \rightleftharpoons [Zn(OH)_4]^{2-}$	2×10^{20}
Complexes with Bidentate Ligands*	
$Mn^{2+} + 3\ en \rightleftharpoons [Mn(en)_3]^{2+}$	6.5×10^{5}
$Fe^{2+} + 3\ en \rightleftharpoons [Fe(en)_3]^{2+}$	5.2×10^{9}
$Co^{2+} + 3\ en \rightleftharpoons [Co(en)_3]^{2+}$	1.3×10^{14}
$Co^{3+} + 3\ en \rightleftharpoons [Co(en)_3]^{3+}$	4.8×10^{48}
$Ni^{2+} + 3\ en \rightleftharpoons [Ni(en)_3]^{2+}$	4.1×10^{17}
$Cu^{2+} + 2\ en \rightleftharpoons [Cu(en)_2]^{2+}$	3.5×10^{19}
$Mn^{2+} + 3\ bipy \rightleftharpoons [Mn(bipy)_3]^{2+}$	1×10^{6}
$Fe^{2+} + 3\ bipy \rightleftharpoons [Fe(bipy)_3]^{2+}$	1.6×10^{17}
$Ni^{2+} + 3\ bipy \rightleftharpoons [Ni(bipy)_3]^{2+}$	3.0×10^{20}
$Co^{2+} + 3\ bipy \rightleftharpoons [Co(bipy)_3]^{2+}$	8×10^{15}
$Mn^{2+} + 3\ phen \rightleftharpoons [Mn(phen)_3]^{2+}$	2×10^{10}
$Fe^{2+} + 3\ phen \rightleftharpoons [Fe(phen)_3]^{2+}$	1×10^{21}
$Co^{2+} + 3\ phen \rightleftharpoons [Co(phen)_3]^{2+}$	6×10^{19}
$Ni^{2+} + 3\ phen \rightleftharpoons [Ni(phen)_3]^{2+}$	2×10^{24}
$Co^{2+} + 3C_2O_4{}^{2-} \rightleftharpoons [Co(C_2O_4)_3]^{4-}$	4.5×10^{6}
$Fe^{3+} + 3C_2O_4{}^{2-} \rightleftharpoons [Fe(C_2O_4)_3]^{3-}$	3.3×10^{20}
Complexes of Other Polydentate Ligands*	
$Zn^{2+} + EDTA^{4-} \rightleftharpoons [Zn(EDTA)]^{2-}$	3.8×10^{16}
$Mg^{2+} + 2NTA^{3-} \rightleftharpoons [Mg(NTA)_2]^{4-}$	1.6×10^{10}
$Ca^{2+} + 2NTA^{3-} \rightleftharpoons [Ca(NTA)_2]^{4-}$	3.2×10^{11}

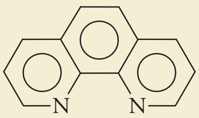
*en = ethylenediamine

bipy = bipyridyl



bipyridyl

phen = 1,10-phenanthroline



1,10-phenanthroline

$EDTA^{4-}$ = ethylenediaminetetraacetate ion

NTA^{3-} = nitrilotriacetate ion

Table C.8 Ionization Constants of Weak Acids and Bases (Alternative Formulas in Parentheses)

Monoprotic Acid	Name	K_a
$HC_2O_2Cl_3$ (Cl_3CCO_2H)	trichloroacetic acid	2.2×10^{-1}
HIO_3	iodic acid	1.7×10^{-1}
$HC_2HO_2Cl_2$ (Cl_2CHCO_2H)	dichloroacetic acid	5.0×10^{-2}
$HC_2H_2O_2Cl$ (ClH_2CCO_2H)	chloroacetic acid	1.4×10^{-3}
HNO_2	nitrous acid	4.6×10^{-4}
HF	hydrofluoric acid	3.5×10^{-4}
$HOCN$	cyanic acid	2×10^{-4}
$HCHO_2$ (HCO_2H)	formic acid	1.8×10^{-4}
$HC_3H_5O_3$ $[CH_3CH(OH)CO_2H]$	lactic acid	1.4×10^{-4}
$HC_4H_3N_2O_3$	barbituric acid	9.8×10^{-5}
$HC_7H_5O_2$ $(C_6H_5CO_2H)$	benzoic acid	6.3×10^{-5}
$HC_4H_7O_2$ $(CH_3CH_2CH_2CO_2H)$	butanoic acid	1.5×10^{-5}
HN_3	hydrazoic acid	2.5×10^{-5}
$HC_2H_3O_2$ (CH_3CO_2H)	acetic acid	1.8×10^{-5}
$HC_3H_5O_2$ $(CH_3CH_2CO_2H)$	propanoic acid	1.3×10^{-5}
$HC_6H_4NO_2$	nicotinic acid (niacin)	1.4×10^{-5}
$HOCl$	hypochlorous acid	3.0×10^{-8}
$HOBr$	hypobromous acid	2.1×10^{-9}
HCN	hydrocyanic acid	4.9×10^{-10}
HC_6H_5O	phenol	1.3×10^{-10}
HOI	hypoiodous acid	2.3×10^{-11}
H_2O_2	hydrogen peroxide	2.4×10^{-12}

Polyprotic Acid	Name	K_{a_1}	K_{a_2}	K_{a_3}
H_2SO_4	sulfuric acid	large	1.2×10^{-2}	
H_2CrO_4	chromic acid	5.0	1.5×10^{-6}	
$H_2C_2O_4$	oxalic acid	6.0×10^{-2}	6.1×10^{-5}	
H_3PO_3	phosphorous acid	5.0×10^{-2}	2.0×10^{-7}	
$H_2S(aq)$	hydrosulfuric acid	8.9×10^{-8}	1×10^{-19}	
H_2SO_3	sulfurous acid	1.2×10^{-2}	6.6×10^{-8}	
H_2SeO_4	selenic acid	large	1.2×10^{-2}	
H_2SeO_3	selenous acid	4.5×10^{-3}	1.1×10^{-8}	
H_6TeO_6	telluric acid	2×10^{-8}	1×10^{-11}	
H_2TeO_3	tellurous acid	3.3×10^{-3}	2.0×10^{-8}	
$H_2C_3H_2O_4$ $(HO_2CCH_2CO_2H)$	malonic acid	1.4×10^{-3}	2.0×10^{-6}	
$H_2C_8H_4O_4$	phthalic acid	1.1×10^{-3}	3.9×10^{-6}	
$H_2C_4H_4O_6$	tartaric acid	9.2×10^{-4}	4.3×10^{-5}	
$H_2C_6H_6O_6$	ascorbic acid	8.0×10^{-5}	1.6×10^{-12}	
H_2CO_3	carbonic acid	4.3×10^{-7}	5.6×10^{-11}	
H_3PO_4	phosphoric acid	7.5×10^{-3}	6.2×10^{-8}	4.2×10^{-13}
H_3AsO_4	arsenic acid	5.5×10^{-3}	1.7×10^{-7}	5.1×10^{-12}
$H_3C_6H_5O_7$	citric acid	7.1×10^{-4}	1.7×10^{-5}	6.3×10^{-6}

(*Continued*)

Table C.8 Ionization Constants of Weak Acids and Bases (Alternative Formulas in Parentheses) *(Continued)*

Weak Base	Name	K_b
$(CH_3)_2NH$	dimethylamine	9.6×10^{-4}
$C_4H_9NH_2$	butylamine	5.9×10^{-4}
CH_3NH_2	methylamine	4.4×10^{-4}
$CH_3CH_2NH_2$	ethylamine	4.3×10^{-4}
$(CH_3)_3N$	trimethylamine	7.4×10^{-5}
NH_3	ammonia	1.8×10^{-5}
$C_{21}H_{22}N_2O_2$	strychnine	1.8×10^{-6}
N_2H_4	hydrazine	1.3×10^{-6}
$C_{17}H_{19}NO_3$	morphine	1.6×10^{-6}
NH_2OH	hydroxylamine	1.1×10^{-8}
C_5H_5N	pyridine	1.7×10^{-9}
$C_6H_5NH_2$	aniline	3.9×10^{-10}
PH_3	phosphine	10^{-28}

Table C.9 Standard Reduction Potentials (25 °C)

E° (Volts)	Half-Cell Reaction
+2.87	$F_2(g) + 2e^- \rightleftharpoons 2F^-(aq)$
+2.08	$O_3(g) + 2H^+(aq) + 2e^- \rightleftharpoons O_2(g) + H_2O$
+2.01	$S_2O_8^{2-}(aq) + 2e^- \rightleftharpoons 2SO_4^{2-}(aq)$
+1.82	$Co^{3+}(aq) + e^- \rightleftharpoons Co^{2+}(aq)$
+1.77	$H_2O_2(aq) + 2H^+(aq) + 2e^- \rightleftharpoons 2H_2O$
+1.695	$MnO_4^-(aq) + 4H^+(aq) + 3e^- \rightleftharpoons MnO_2(s) + 2H_2O$
+1.69	$PbO_2(s) + HSO_4^-(aq) + 3H^+(aq) + 2e^- \rightleftharpoons PbSO_4(s) + 2H_2O$
+1.63	$2HOCl(aq) + 2H^+(aq) + 2e^- \rightleftharpoons Cl_2(g) + 2H_2O$
+1.51	$Mn^{3+}(aq) + e^- \rightleftharpoons Mn^{2+}(aq)$
+1.51	$MnO_4^-(aq) + 8H^+(aq) + 5e^- \rightleftharpoons Mn^{2+}(aq) + 4H_2O$
+1.46	$PbO_2(s) + 4H^+(aq) + 2e^- \rightleftharpoons Pb^{2+}(aq) + 2H_2O$
+1.44	$BrO_3^-(aq) + 6H^+(aq) + 6e^- \rightleftharpoons Br^-(aq) + 3H_2O$
+1.42	$Au^{3+}(aq) + 3e^- \rightleftharpoons Au(s)$
+1.36	$Cl_2(g) + 2e^- \rightleftharpoons 2Cl^-(aq)$
+1.33	$Cr_2O_7^{2-}(aq) + 14H^+(aq) + 6e^- \rightleftharpoons 2Cr^{3+}(aq) + 7H_2O$
+1.24	$O_3(g) + H_2O + 2e^- \rightleftharpoons O_2(g) + 2OH^-(aq)$
+1.23	$MnO_2(s) + 4H^+(aq) + 2e^- \rightleftharpoons Mn^{2+}(aq) + 2H_2O$
+1.23	$O_2(g) + 4H^+(aq) + 4e^- \rightleftharpoons 2H_2O$
+1.20	$Pt^{2+}(aq) + 2e^- \rightleftharpoons Pt(s)$
+1.07	$Br_2(aq) + 2e^- \rightleftharpoons 2Br^-(aq)$
+0.96	$NO_3^-(aq) + 4H^+(aq) + 3e^- \rightleftharpoons NO(g) + 2H_2O$
+0.94	$NO_3^-(aq) + 3H^+(aq) + 2e^- \rightleftharpoons HNO_2(aq) + H_2O$
+0.91	$2Hg^{2+}(aq) + 2e^- \rightleftharpoons Hg_2^{2+}(aq)$
+0.87	$HO_2^-(aq) + H_2O + 2e^- \rightleftharpoons 3OH^-(aq)$
+0.80	$NO_3^-(aq) + 4H^+(aq) + 2e^- \rightleftharpoons 2NO_2(g) + 2H_2O$
+0.80	$Ag^+(aq) + e^- \rightleftharpoons Ag(s)$
+0.77	$Fe^{3+}(aq) + e^- \rightleftharpoons Fe^{2+}(aq)$
+0.69	$O_2(g) + 2H^+(aq) + 2e^- \rightleftharpoons H_2O_2(aq)$
+0.54	$I_2(s) + 2e^- \rightleftharpoons 2I^-(aq)$
+0.49	$NiO_2(s) + 2H_2O + 2e^- \rightleftharpoons Ni(OH)_2(s) + 2OH^-(aq)$
+0.45	$SO_2(aq) + 4H^+(aq) + 4e^- \rightleftharpoons S(s) + 2H_2O$
+0.401	$O_2(g) + 2H_2O + 4e^- \rightleftharpoons 4OH^-(aq)$
+0.34	$Cu^{2+}(aq) + 2e^- \rightleftharpoons Cu(s)$
+0.27	$Hg_2Cl_2(s) + 2e^- \rightleftharpoons 2Hg(l) + 2Cl^-(aq)$
+0.25	$PbO_2(s) + H_2O + 2e^- \rightleftharpoons PbO(s) + 2OH^-(aq)$
+0.2223	$AgCl(s) + e^- \rightleftharpoons Ag(s) + Cl^-(aq)$
+0.172	$SO_4^{2-}(aq) + 4H^+(aq) + 2e^- \rightleftharpoons H_2SO_3(aq) + H_2O$
+0.169	$S_4O_6^{2-}(aq) + 2e^- \rightleftharpoons 2S_2O_3^{2-}(aq)$
+0.16	$Cu^{2+}(aq) + e^- \rightleftharpoons Cu^+(aq)$
+0.15	$Sn^{4+}(aq) + 2e^- \rightleftharpoons Sn^{2+}(aq)$
+0.14	$S(s) + 2H^+(aq) + 2e^- \rightleftharpoons H_2S(g)$
+0.07	$AgBr(s) + e^- \rightleftharpoons Ag(s) + Br^-(aq)$
0 (exactly)	$2H^+(aq) + 2e^- \rightleftharpoons H_2(g)$
−0.13	$Pb^{2+}(aq) + 2e^- \rightleftharpoons Pb(s)$

−2.92	$Cs^+(aq) + e^- \rightleftharpoons Cs(s)$
−2.92	$K^+(aq) + e^- \rightleftharpoons K(s)$
−2.93	$Rb^+(aq) + e^- \rightleftharpoons Rb(s)$
−3.05	$Li^+(aq) + e^- \rightleftharpoons Li(s)$

Glossary

This glossary has the definitions of the key terms that were marked in boldface throughout the chapters plus a few additional terms. The numbers in parentheses that follow the definitions are the numbers of the sections in which the glossary entries received their principal discussions.

A

Abbreviated Electron Configurations: A shorthand method to write electron configurations using the preceding noble gase to represent core electrons. (8.8)

Absolute Zero: 0 K, −273.15 °C. Nature's lowest temperature. (2.2, 11.3)

Acceptor: A Lewis acid; the central metal ion in a complex ion. (18.4, 22.1)

Accuracy: The closeness of a measurement to the true value. (2.3)

Acid: *Arrhenius definition:* A substance that produces hydronium ions (hydrogen ions) in water. (5.3)
Brønsted definition: A proton donor. (16.1)
Lewis definition: An electron-pair acceptor. (16.4)

Acid Anhydride: Generally, an oxide of a nonmetal. (5.3)

Acid–Base Indicator: A dye with one color in acid and another color in base. (5.3, 5.8)

Acid–Base Neutralization: The reaction of an acid with a base. (5.3, 16.4)

Acid Ionization Constant (K_a):

$$K_a = \frac{[H^+][A^-]}{[HA]} \quad \text{for the equilibrium,}$$

$$HA \rightleftharpoons H^+ + A^- \qquad (17.3)$$

Acid Rain: Rain made acidic by dissolving sulfur and nitrogen oxides from the atmosphere.

Acid Salt: A salt of a partially neutralized polyprotic acid, for example, $NaHSO_4$ or $NaHCO_3$. (5.4)

Acid Solubility Product: The special solubility product expression for metal sulfides in dilute acid and related to the equation for their dissolving. For a divalent metal sulfide, MS,

$$MS(s) + 2H^+(aq) \rightleftharpoons M^{2+}(aq) + H_2S(aq)$$

$$K_{spa} = \frac{[M^{2+}][H_2S]}{[H^+]^2} \qquad (18.2)$$

Acidic Anhydride: An oxide that reacts with water to make the solution acidic. (5.3)

Acidic Solution: An aqueous solution in which $[H^+] > [OH^-]$. (7.1)

Actinide Elements (Actinide Series): Elements 90–103. (3.2)

Activated Complex: The chemical species that exists with partly broken and partly formed bonds in the transition state. (14.6)

Activation Energy (E_a): The minimum kinetic energy that must be possessed by the reactants in order to result in an effective collision (one that produces products). (14.5)

Activities: Effective concentrations which properly should be substituted into a mass action expression to satisfy the equilibrium law. The activity of a solid is defined as having a value of 1. (15.4)

Activity: For a radioactive material, the number of disintegrations per second. (21.6)

Activity Series: A list of metals in order of their reactivity as reducing agents. (6.4)

Actual Yield: See *Yield, Actual.*

Addition Compound: A molecule formed by the joining of two simpler molecules through formation of a covalent bond (usually a coordinate covalent bond). (9.8)

Addition Polymer: A polymer formed by the simple addition of one monomer unit to another, a process that continues over and over until a very long chain of monomer units is produced. (23.5)

Addition Reaction: The addition of a molecule to a double or triple bond. (23.2)

Adiabatic Change: A change within a system during which no energy enters or leaves the system. (7.3, 19.1)

Aerogel: A modern ceramic that is extremely porous and has a low density (16.6)

Alcohol: An organic compound whose molecules have the —OH group attached to tetrahedral carbon. (3.6, 9.6, 22.3)

Aldehyde: An organic compound whose molecules have the —OH group. (9.6)

Alkali Metals: The Group 1A elements (except hydrogen)—lithium, sodium, potassium, rubidium, cesium, and francium. (3.2)

Alkaline Battery (Alkaline Dry Cell): A zinc–manganese dioxide galvanic cell of 1.54 V used commonly in flashlight batteries. (20.6)

Alkaline Earth Metals: The Group 2A elements—beryllium, magnesium, calcium, strontium, barium, and radium. (3.2)

Alkane: A hydrocarbon whose molecules have only single bonds. (3.6, 23.2)

Alkene: A hydrocarbon whose molecules have one or more double bonds. (23.2)

Alkyl Group: An organic group of carbon and hydrogen atoms related to an alkane but with one less hydrogen atom (e.g., CH_3—, methyl; CH_3CH_2—, ethyl). (16.6, 23.2)

Alkyne: A hydrocarbon whose molecules have one or more triple bonds. (23.2)

Allotrope: One of two or more forms of an element. (10.10)

Allotropy: The existence of an element in two or more molecular or crystalline forms called allotropes. (10.10)

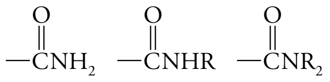
Alpha Particle: The nucleus of a helium atom. (22.3)

Alpha Radiation: A high-velocity stream of alpha particles produced by radioactive decay. (21.3)

Alum: A double salt with the general formula $M^+M^{3+}(SO_4)_2 \cdot 12H_2O$, such as potassium alum: $KAl(SO_4)_2 \cdot 12H_2O$.

Amalgam: A solution of a metal in mercury.

Amide: An organic compound whose molecules have any one of the following groups: (23.4)



$$\overset{O}{\overset{\|}{—CNH_2}} \qquad \overset{O}{\overset{\|}{—CNHR}} \qquad \overset{O}{\overset{\|}{—CNR_2}}$$

α-Amino Acid: One of about 20 monomers of polypeptides. (23.6)

Amine: An organic compound whose molecules contain the group NH_2, NHR, or NR_2. (9.6, 23.4)

Amorphous Solid: A noncrystalline solid. A glass. (12.11)

Ampere (A): The SI unit for electric current; one coulomb per second. (20.8)

Amphiprotic Compound: A compound that can act either as a proton donor or as a proton acceptor; an amphoteric compound. (16.1)

Amphoteric Compound: A compound that can react as either an acid or a base. (16.1)

Amplitude: The height of a wave, which is a measure of the wave's intensity. (8.1)

amu: See *Atomic Mass Unit.*

Angstrom (Å): 1 Å = 10^{-10} m = 100 pm = 0.1 nm. (8.10)

Anhydrous: Without water. (1.5)

Anion: A negatively charged ion. (3.4)

Anode: The positive electrode in a gas discharge tube. The electrode at which oxidation occurs during an electrochemical change. (3.1, 20.1)

Antibonding Electrons: Electrons that occupy antibonding molecular orbitals. (10.7)

Antibonding Molecular Orbital: A molecular orbital that denies electron density to the space between nuclei and destabilizes a molecule when occupied by electrons. (10.7)

Antimatter: Any particle annihilated by a particle of ordinary matter. (22.3)

Aqua Regia: One part concentrated nitric acid and three parts concentrated hydrochloric acid (by volume).

Aqueous Solution: A solution that has water as the solvent.

Aromatic Compound: An organic compound whose molecules have the benzene ring system. (23.2)

Aromatic Hydrocarbon: Hydrocarbons that contain a benzene ring or similar ring systems with alternating single and double bonds. (23.2)

Arrhenius Acid: See *Acid*.

Arrhenius Base: See *Base*.

Arrhenius Equation: An equation that relates the rate constant of a reaction to the reaction's activation energy. (14.7)

Association: The joining together of molecules by hydrogen bonds. (13.7)

Asymmetric Carbon Atom: A carbon atom that is bonded to four different groups and which is a chiral center. (23.1)

Atmosphere, Standard (atm): 101,325 Pa. The pressure that supports a column of mercury 760 mm high at 0 °C; 760 torr. (7.5, 11.2)

Atmospheric Pressure: The pressure exerted by the mixture of gases in our atmosphere. (7.5, 11.2)

Atom: A neutral particle having one nucleus; the smallest representative sample of an element. (1.2)

Atomic force microscope: A modern instrument that determines the topology of materials with a resolution on the order of atomic dimensions. Orientations of atoms and structures of molecular assemblies on these surfaces can be deduced from these measurements. (1.6)

Atomic Mass: The average mass (in u) of the atoms of the isotopes of a given element as they occur naturally. (3.1)

Atomic Mass Unit (u): $1.6605402 \times 10^{-24}$ g; 1/12th the mass of one atom of carbon-12. Sometimes given the symbol amu. (3.1)

Atomic Number: The number of protons in a nucleus. (3.1)

Atomic Radiation: Radiation consisting of particles or electromagnetic radiation given off by radioactive elements. (21.3)

Atomic Spectrum: The line spectrum produced when energized or excited atoms emit electromagnetic radiation. (8.2)

Atomic Weight: See *Atomic Mass*.

Atomization Energy (ΔH_{atom}): The energy needed to rupture all of the bonds in one mole of a substance in the gas state and produce its atoms, also in the gas state. (19.10)

Aufbau Principle: A set of rules enabling the construction of an electron structure of an atom from its atomic number. (8.7)

Average: See *Mean*.

Average Bond Order: The bond order of two or more equivalent bonds, determined by dividing the total number of sigma and pi bonds by the number of bonding electron domains. (9.9)

Avogadro's Number (Avogadro's Constant): 6.022×10^{23}; the number of particles or formula units in one mole. (4.1)

Avogadro's Principle: Equal volumes of gases contain equal numbers of molecules when they are at identical temperatures and pressures. (11.4)

Axial Bonds: Covalent bonds oriented parallel to the vertical axis in a trigonal bipyramidal molecule. (10.1)

Azimuthal Quantum Number: The quantum number. (8.5) (See also *Secondary Quantum Number*.)

B

Backbone (Polymer): The long chain of atoms in a polymer to which other groups are attached. (23.5)

Background Radiation: The atomic radiation from the natural radionuclides in the environment and from cosmic radiation. (21.6)

Balance: An apparatus for measuring mass. (2.2)

Balanced Equation: A chemical equation that has on opposites sides of the arrow the same number of each atom and the same net charge. (1.6, 4.4)

Ball and Stick Model: The representation of molecules using colored balls for atoms and sticks representing bonds. (1.5)

Band Gap: The energy difference between the valence band and the conduction band. (10.9)

Band Theory: A theory used to explain electron conduction in metals, semiconductors and insulators. (10.9)

Band of Stability: The envelope that encloses just the stable nuclides in a plot of all nuclides constructed according to their numbers of neutrons versus their numbers of protons. (21.4)

Bar: The standard pressure for thermodynamic quantities; 1 bar = 105 pascals, 1 atm = 101,325 Pa. (7.5, 11.2, 19.5)

Barometer: An apparatus for measuring atmospheric pressure. (11.2)

Base: *Arrhenius theory:* A substance that releases OH^- ions in water. (5.3)
Brønsted theory: A proton acceptor. (16.1)
Lewis theory: An electron-pair acceptor. (16.3)

Base Anhydride: Oxides of metals that when dissolved in water produce a basic solution (5.3)

Base Ionization Constant, K_b:

$$K_b = \frac{[BH^+][OH^-]}{[B]} \text{ for the equilibrium,}$$

$$B + H_2O \rightleftharpoons BH^+ + OH^- \qquad (17.3)$$

Base Units: The units of the fundamental measurements of the SI. (2.2)

Basic Anhydride: An oxide that can neutralize acid or that reacts with water to give OH^-. (5.3)

Basic Solution: An aqueous solution in which $[H^+] < [OH^-]$. (17.1)

Battery: One or more galvanic cells arranged to serve as a practical source of electricity. (20.6)

Becquerel (Bq): 1 disintegration s^{-1}. The SI unit for the activity of a radioactive source. (21.6)

Bent Molecule (V-Shaped Molecule): A molecule that is nonlinear. (10.2)

Beta Particle: An electron emitted by radioactive decay. (22.3)

Beta Radiation: A stream of electrons produced by radioactive decay. (22.3)

Bidentate Ligand: A ligand that has two atoms that can become simultaneously attached to the same metal ion. (22.1)

Bimolecular Collision: A collision of two molecules. (14.8)

Binary Acid: An acid with the general formula H_nX, where X is a nonmetal. (5.4, 16.3)

Binary Compound: A compound composed of two different elements. (3.4)

Binding Energy, Nuclear: The energy equivalent of the difference in mass between an atomic nucleus and the sum of the masses of its nucleons. (21.2)

Biochemistry: The study of the organic substances in organisms. (3.6, 23.6)

Biological Catalyst: Biological molecule such as an enzyme that catalyzes a chemical reaction.

Black Phosphorus: An allotrope of phosphorus that has a layered structure. (10.10)

Body-Centered Cubic (bcc) Unit Cell: A unit cell having identical atoms, molecules, or ions at the corners of a cube plus one more particle in the center of the cube. (12.11)

Boiling Point: The temperature at which the vapor pressure of the liquid equals the atmospheric pressure. (12.6)

Boiling Point Elevation: A colligative property of a solution by which the solution's boiling point is higher than that of the pure solvent. (13.7)

Bond Angle: The angle formed by two bonds that extend from the same atom. (10.1)

Bond Dipole: A dipole within a molecule associated with a specific bond. (10.3)

Bond Dissociation Energy: See *Bond Energy*.

Bond Distance: See *Bond Length*.

Bond Energy: The energy needed to break one mole of a particular bond to give electrically neutral fragments. (9.5, 19.10)

Bond Length: The distance between two nuclei that are held together by a chemical bond. (9.5)

Bond Order: The number of electron pairs shared between two atoms. The *net* number of pairs of bonding electrons. (9.8)

$$\text{Bond order} = 1/2 \times (\text{no. of bonding } e^- - \text{no. of antibonding } e^-)$$

Bonding Domain: A region between two atoms that contains one or more electron pairs in bonds and that influences molecular shape. (10.2)

Bonding Electrons: Electrons that occupy bonding molecular orbitals. (10.7)

Bonding Molecular Orbital: A molecular orbital that introduces a buildup of electron density between nuclei and stabilizes a molecule when occupied by electrons. (10.7)

Born-Haber Cycle: A method for visualizing energy contributions to a physical or chemical change such as the dissolution of a compound in a solvent or the formation of a compound. (9.2)

Boundary: The interface between a system and its surroundings across which energy or matter might pass. (7.3)

Boyle's Law: See *Pressure–Volume Law*.

Bragg Equation: $n\lambda = 2d \sin \theta$. The equation used to convert X-ray diffraction data into a crystal structure. (12.12)

Branched-Chain Compound: An organic compound in whose molecules the carbon atoms do not all occur one after another in a continuous sequence. (23.1)

Branching (Polymer): The formation of side chains (branches) along the main backbone of a polymer. (23.5)

Branching Step: A step in a chain reaction that produces more chain-propagating species than it consumes. (Chemistry Outside the Classroom 14.1)

Brine: An aqueous solution of sodium chloride, often with other salts. (20.9)

Brønsted Acid: See *Acid*.

Brønsted Base: See *Base*.

Brownian Motion: The random, erratic motions of colloidally dispersed particles in a fluid. (3.6)

Buckminsterfullerene: The C-60 molecule. Also called buckyball. (10.10)

Buckyball: See *Buckminsterfullerene*.

Buffer: (a) A pair of solutes, a conjugate weak acid–weak base pair, that can keep the pH of a solution almost constant if either acid or base is added. (b) A solution containing such a pair of solutes. (17.7)

Buffer Capacity: A measure of how much strong acid or strong base is needed to change the pH of a buffer by some specified amount. (17.7)

Buret: A long tube of glass usually marked in mL and 0.1 mL units and equipped with a stopcock for the controlled addition of a liquid to a receiving flask. (5.8)

By-product: The substances formed by side reactions. (4.6)

C

Calorie (cal): 4.184 J. The energy that will raise the temperature of 1.00 g of water from 14.5 to 15.5 °C. (The nutritional *Calorie*, with a capital C, means 1000 cal or 1 kcal.) (7.1)

Calorimeter: An apparatus used in the determination of the heat of a reaction. (7.5)

Calorimetry: The science of measuring the quantities of heat that are involved in a chemical or physical change. (7.5)

Carbohydrates: Polyhydroxyaldehydes or polyhydroxyketones or substances that yield these by hydrolysis and that are obtained from plants or animals. (23.6)

Carbon Nanotube: Tubular carbon molecules that can be visualized as rolled up sheets of graphite (with hexagonal rings of carbon atoms) capped at each end by half of a spherical fullerene molecule. (10.10)

Carbon Ring: A series of carbon atoms arranged in a ring. (23.1)

Carbonyl Group: An organic functional group consisting of a carbon atom joined to an oxygen atom by a double bond; $C{=}O$. (9.6, 23.3)

Carboxyl Group: The organic functional group of an acid consisting of a carbon joined to an oxygen atom with a double bond and an OH group; $-CO_2H$ or $-COOH$. (9.6, 23.3)

Carboxylic Acid: An organic compound whose molecules have the carboxyl group (9.6, 23.3)

Catalysis: Rate enhancement caused by a catalyst. (14.9)

Catalyst: A substance that in relatively small proportion accelerates the rate of a reaction without being permanently chemically changed. (14.9)

Catenation: The linking together of atoms of the same element to form chains.

Cathode: The negative electrode in a gas discharge tube. The electrode at which reduction occurs during an electrochemical change. (3.1, 20.1)

Cathode Ray: A stream of electrons ejected from a hot metal and accelerated toward a positively charged site in a vacuum tube. (3.1)

Cation: A positively charged ion. (3.4)

Cell Potential, E_{cell}: The potential (voltage) of a galvanic cell when no current is drawn from the cell. (20.2)

Cell Reaction: The overall chemical change that takes place in an electrolytic cell or a galvanic cell. (20.1)

Celsius Scale: A temperature scale on which water freezes at 0 °C and boils at 100 °C (at 1 atm) and that has 100 divisions called Celsius degrees between those two points. (2.2)

Centimeter (cm): 0.01 m. (2.2)

Chain-Growth Polymer: See *Addition Polymer*.

Chain Reaction: A self-sustaining change in which the products of one event cause one or more new events. (Chemistry Outside the Classroom. 14.1)

Change of State: Transformation of matter from one physical state to another. In thermochemistry, any change in a variable used to define the state of a particular system—a change in composition, pressure, volume, or temperature. (12.4)

Charles' Law: See *Temperature–Volume Law*.

Chelate: A complex ion containing rings formed by polydentate ligands. (22.1)

Chelate Effect: The extra stability found in complexes that contain chelate rings. (22.1)

Chemical Bond: The force of electrical attraction that holds atoms together in compounds. (3.6, 9 Introduction)

Chemical Change: A change that converts substances into other substances; a chemical reaction. (1.3)

Chemical Energy: The potential energy of chemicals that is transferred during chemical reactions. (7.1)

Chemical Equation: A before-and-after description that uses formulas and coefficients to represent a chemical reaction. (1.6)

Chemical Equilibrium: Dynamic equilibrium in a chemical system. (5.3, 15.1)

Chemical Formula: A formula written using chemical symbols and subscripts that describes the composition of a chemical compound or element. (1.5)

Chemical Kinetics: The study of rates of reaction. (14 Introduction)

Chemical Property: The ability of a substance, either by itself or with other substances, to undergo a change into new substances. (2.1)

Chemical Reaction: A change in which new substances (products) form from starting materials (reactants). (1.3)

Chemical Symbol: A formula for an element. (1.3)

Chemical Thermodynamics: See *Thermodynamics.*

Chemistry: The study of the compositions of substances and the ways by which their properties are related to their compositions. (1.1)

Chirality: The “handedness” of an object; the property of an object (like a molecule) that makes it unable to be superimposed onto a model of its own mirror image. (22.4)

Cis Isomer: A stereoisomer whose uniqueness is in having two groups on the same side of some reference plane. (22.4)

Clausius–Clapeyron Equation: The relationship between the vapor pressure, the temperature, and the molar heat of vaporization of a substance (where C is a constant). (12.8)

$$\ln P = \frac{\Delta H_{\text{vap}}}{RT} + C$$

Closed-End Manometer: See *Manometer.*

Closed System: A system that can absorb or release energy but not mass across the boundary between the system and its surroundings. (7.3)

Closest-Packed Structure: A crystal structure in which atoms or molecules are packed as efficiently as possible. (12.11)

Codon: An individual unit of hereditary instruction that consists of three, side by side, side chains on a molecule of mRNA. (23.7)

Coefficients: Numbers in front of formulas in chemical equations. (1.6)

Coinage Metals: Copper, silver, and gold.

Collapsing Atom Paradox: The paradox faced by classical physics that predicts a moving electron in an atom should emit energy and spiral into the nucleus. (8 Introduction)

Colligative Property: A property such as vapor pressure lowering, boiling point elevation, freezing point depression, and osmotic pressure whose physical value depends only on the ratio of the numbers of moles of solute and solvent particles and not on their chemical identities. (13.7)

Collision Theory: The rate of a reaction is proportional to the number of effective collisions that occur each second between the reactants. (14.5)

Colloid: Particles with at least one dimension between 1 and 100 nm suspended in a solvent. (13.8)

Combined Gas Law: See *Gas Law, Combined.*

Combustion: A rapid reaction with oxygen accompanied by a flame and the evolution of heat and light. (6.5)

Combustion Analysis: A method for obtaining percentage composition data for organic compounds. (4.3)

Common Ion: The ion in a mixture of ionic substances that is common to the formulas of at least two. (17.7)

Common Ion Effect: The solubility of one salt is reduced by the presence of another having a common ion. (17.7)

Competing Reaction: A reaction that reduces the yield of the main product by forming by-products. (4.6)

Complementary Colors: Two colors, when mixed, result in a neutral color such as gray, black or white. (22.5)

Complex Ion (Complex): The combination of one or more anions or neutral molecules (ligands) with a metal ion. (15.6, 18.4, 22.1)

Compound: A substance consisting of chemically combined atoms from two or more elements and present in a definite ratio. (1.3)

Compound Nucleus: An atomic nucleus carrying excess energy following its capture of some bombarding particle. (21.5)

Compressibility: Capable of undergoing a reduction in volume under increasing pressure. (11.1, 12.3)

Concentrated Solution: A solution that has a large ratio of the amounts of solute to solvent. (5.1)

Concentration: The ratio of the quantity of solute to the quantity of solution (or the quantity of solvent). (5.1) (See *Molal Concentration, Molar Concentration, Mole Fraction, Percentage Concentration.*)

Concentration Table: A part of the strategy for organizing data needed to make certain calculations, particularly any involving equilibria. (15.7)

Conclusion: A statement that is based on what we think about a series of observations. (1.2)

Condensation: The change of a vapor to its liquid or solid state. (12.4)

Condensation Polymer (Step-Growth Polymer): A polymer formed from monomers by splitting out a small molecule such as H_2O or CH_3OH. (23.5)

Condensation Polymerization: The process of forming a condensation polymer. (23.5)

Condensed Formula: Generally a formula of an organic compound written to show the sequence of carbon atoms and functional groups without individual bonds. (9.6, 23.1)

Condensed Structural Formulas (Condensed Structures): See *Condensed Formula.*

Conduction Band: In band theory, this consists of any band of atomic energy levels that is continuous throughout the solid and empty or partially filled with electrons. (10.9)

Conformation: A particular relative orientation or geometric form of a flexible molecule. (10.5)

Conjugate Acid: The species in a conjugate acid–base pair that has the greater number of H-units. (16.1)

Conjugate Acid–Base Pair: Two substances (ions or molecules) whose formulas differ by only one H-unit. (16.1)

Conjugate Base: The species in a conjugate acid–base pair that has the fewer number of H-units. (16.1)

Conservation of Energy, Law of: See *Law of Conservation of Energy.*

Conservation of Mass–Energy, Law of: See *Law of Conservation of Mass–Energy.*

Continuous Spectrum: The electromagnetic spectrum corresponding to the mixture of frequencies present in white light. (8.2)

Contributing Structure: One of a set of two or more Lewis structures used in applying the theory of resonance to the structure of a compound. A resonance structure. (9.9)

Conversion Factor: A ratio constructed from the relationship between two units such as 2.54 cm/1 in., from 1 in. = 2.54 cm. (2.4)

Cooling Curve: A graph showing how the temperature of a substance changes as heat is removed from it at a constant rate as the substance undergoes changes in its physical state. (12.7)

Coordinate Covalent Bond: A covalent bond in which both electrons originated from one of the joined atoms, but otherwise like a covalent bond in all respects. (9.8)

Coordination Compound (Coordination Complex): A complex or its salt. (19.4, 22.1)

Coordination Number: The number of donor atoms that surround a metal ion. (22.3)

Copolymer: A polymer made from two or more different monomers. (22.6)

Core Electrons: The inner electrons of an atom that are not exposed to the electrons of other atoms when chemical bonds form. (8.10)

Corrosion: The slow oxidation of metals exposed to air or water. (6.5)

Coulomb (C): The SI unit of electrical charge; the charge on 6.25×10^{18} electrons; the amount of charge that passes a fixed point of a wire conductor when a current of 1 A flows for 1 s. (20.2)

Coulomb's Law: This is the mathematical equation that describes the attractive and repulsive forces between charged particles. (9.2)

Counter Ions: Ions present in a system to assure that the overall charge is zero. (22.1)

Covalent Bond: A chemical bond that results when atoms share electron pairs. (9.5)

Covalent Crystal (Network Solid): A crystal in which the lattice positions are occupied by atoms that are covalently bonded to the atoms at adjacent lattice sites. (12.13)

Critical Mass: The mass of a fissile isotope above which a self-sustaining chain reaction occurs. (21.8)

Critical Point: The point at the end of a vapor pressure versus temperature curve for a liquid and that corresponds to the critical pressure and the critical temperature. (12.10)

Critical Pressure (P_c): The vapor pressure of a substance at its critical temperature. (12.10)

Critical Temperature (T_c): The temperature above which a substance cannot exist as a liquid regardless of the pressure. (12.10)

Crystal Field Splitting (Δ): The difference in energy between sets of *d* orbitals in a complex ion. (22.5)

Crystal Field Theory: A theory that considers the effects of the polarities or the charges of the ligands in a complex ion on the energies of the *d* orbitals of the central metal ion. (22.5)

Crystal Lattice: The repeating symmetrical pattern of atoms, molecules, or ions that occurs in a crystal. (12.11)

Cubic Closest Packing (ccp): Efficient packing of spheres with an A-B-C-A-B-C ... alternating stacking of layers of spheres. (12.11)

Cubic Meter (m^3): The SI derived unit of volume. (2.2)

Curie (Ci): A unit of activity for radioactive samples, equal to 3.7×10^{10} disintegrations per second. (21.6)

D

Dalton: One atomic mass unit, u.

Dalton's Atomic Theory: Matter consists of tiny, indestructible particles called atoms. All atoms of one element are identical. The atoms of different elements have different masses. Atoms combine in definite ratios by atoms when they form compounds. (1.4)

Dalton's Law of Partial Pressures: See *Partial Pressures, Law of.*

Data: The information (often in the form of physical quantities) obtained in an experiment or other experience or from references. (1.2)

Debye: Unit used to express dipole moments. $1 \text{ D} \times 3.34 \times 10^{-30}$ C m (coulomb meter). (9.7)

Decay Constant: The first-order rate constant for radioactive decay. (21.6)

Decimal Multipliers: Factors—exponentials of 10 or decimals—that are used to define larger or smaller SI units. (2.2)

Decomposition: A chemical reaction that changes one substance into two or more simpler substances. (1.3)

Dehydration: Removal of water from a substance. (23.3)

Dehydration Reaction: Formation of a carbon–carbon double bond by removal of the components of water from an alcohol. (23.3)

Deliquescent Compound: A compound able to absorb enough water from humid air to form a concentrated solution.

Delocalization Energy: The difference between the energy a substance would have if its molecules had no delocalized molecular orbitals and the energy it has because of such orbitals. (10.8)

Delocalized Molecular Orbital: A molecular orbital that spreads over more than two nuclei. (10.8)

ΔH_{fusion}: See *Molar Heat of Fusion*

$\Delta H_{\text{sublimation}}$: See *Molar Heat of Sublimation*

$\Delta H_{\text{vaporization}}$: See *Molar Heat of Vaporization*

Density: The ratio of an object's mass to its volume. (2.5)

Dependent Variable: The experimental variable of a pair of variables whose value is determined by the other, the independent variable.

Deposition: The term describing the opposite of sublimation. (12.4)

Derived Unit: Any unit defined solely in terms of base units. (2.2)

Deuterium: The isotope of hydrogen with a mass number of 2. (21.8)

Diagonal Trend: Physical or chemical properties that generally vary diagonally from one corner to the other in the periodic table (e.g., ionization energy, electron affinity, and electronegativity). (8.10)

Dialysis: The passage of small molecules and ions, but not species of a colloidal size, through a semipermeable membrane. (13.7)

Dialyzing membrane: A membrane that allows the passage of solvent and small solutes through its pores, but large molecules cannot pass through the pores. (13.7)

Diamagnetism: The property experienced by a substance that contains no unpaired electrons whereby the substance is repelled weakly by a magnet. (8.6)

Diamond: A crystalline form of carbon in which each carbon atom is bonded in a tetrahedral structure to four other carbon atoms. (10.10)

Diaphragm Cell: An electrolytic cell used to manufacture sodium hydroxide by the electrolysis of aqueous sodium chloride. (20.9)

Diatomic Substance (Diatomic Molecule): A molecular substance made from two atoms. (1.5)

Diffraction: Constructive and destructive interference by waves. (8.4)

Diffraction Pattern: The image formed on a screen or a photographic film caused by the diffraction of electromagnetic radiation such as visible light or X rays. (12.12)

Diffusion: The spontaneous intermingling of one substance with another. (11.6)

Dilute Solution: A solution in which the ratio of the quantities of solute to solvent is small. (5.1)

Dilution: The process whereby a concentrated solution is made more dilute. (4.6)

Dimensional Analysis: A method for converting one set of units to another that relies on a logical sequence of steps and unit cancellation. (2.4)

Dimer: Two monomer units joined by chemical bonds or intramolecular forces. (13.7)

Dipole (Electric): Partial positive and partial negative charges separated by a distance. (9.7, 12.2)

Dipole–Dipole Attraction: Attraction between molecules that are dipoles. (12.2)

Dipole Moment (μ): The product of the sizes of the partial charges in a dipole multiplied by the distance between them; a measure of the polarity of a molecule. (9.7)

Diprotic Acid: An acid that can furnish two H^+ per molecule. (5.3)

Disaccharide: A carbohydrate whose molecules can be hydrolyzed to two monosaccharides. (23.6)

Dispersions: Mixtures of very small particles of immiscible substances that do not readily separate into different phases. Often used when describing emulsions. (13.8)

Dispersion Forces: Another term for London forces. (12.2)

Disproportionation: A redox reaction in which a portion of a substance is oxidized at the expense of the rest, which is reduced.

Dissociation: The separation of preexisting ions when an ionic compound dissolves or melts. (5.2)

Dissymmetric: Lacking or deficient in symmetry. In a dissymmetric molecule the effects of the individual bond dipoles do not cancel, causing the molecule as a whole to be polar. (10.3)

Distorted Tetrahedron: A description of a molecule in which the central atom is surrounded by five electron pairs, one of which is a lone pair of electrons. The central atom is bonded to four other atoms. The structure is also said to have a seesaw shape. (10.2)

DNA: Deoxyribonucleic acid; a nucleic acid that hydrolyzes to deoxyribose, phosphate ion, adenine, thymine, guanine, and cytosine, and that is the carrier of genes. (23.7)

DNA Double Helix: Two oppositely running strands of DNA held in a helical configuration by inter strand hydrogen bonds. (23.7)

Donor Atom: The atom on a ligand that makes an electron pair available in the formation of a complex. (18.4, 22.1)

Doped: A semiconductor material such as Si or Ge that has small amounts of electron rich (e.g., P) or electron deficient (e.g., B) atoms added. (10.9)

Double Bond: (a) A covalent bond formed by sharing two pairs of electrons. (9.5) (b) A covalent bond consisting of one sigma bond and one pi bond. (10.6)

Double Replacement Reaction (Metathesis Reaction): A reaction of two salts in which cations and anions exchange partners

$$\text{(e.g., } AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3\text{). (5.5)}$$

Downs Cell: An electrolytic cell for the industrial production of sodium. (20.9)

Ductility: A metal's ability to be drawn (or stretched) into wire. (3.3)

Dynamic Equilibrium: A condition in which two opposing processes are occurring at equal rates. (5.3, 14.1)

E

ΔE: See *Internal Energy Change.*

Effective Collision: A collision between molecules that is capable of leading to a net chemical change. (14.5)

Effective Nuclear Charge: The net positive charge an outer electron experiences as a result of the partial screening of the full nuclear charge by core electrons. (8.10)

Effusion: The movement of a gas through a very tiny opening into a region of lower pressure. (11.6)

Effusion, Law of (Graham's Law): The rates of effusion of gases are inversely proportional to the square roots of their densities when compared at identical pressures and temperatures.

$$\text{Effusion rate} \propto \frac{1}{\sqrt{d}} \quad \text{(constant } P \text{ and } T\text{)}$$

where d is the gas density. (11.6)

Einstein Equation: $\Delta E = m_0c^2$ where ΔE is the energy obtained when a quantity of rest mass, Δm_0, is destroyed, or the energy lost when this quantity of mass is created. (21.1)

Electric Dipole: Two poles of electric charge separated by a distance. (9.7)

Electrochemical Change: A chemical change that is caused by or that produces electricity. (20 Introduction)

Electrochemistry: The study of electrochemical changes. (20 Introduction)

Electrolysis: The production of a chemical change by the passage of electricity through a solution that contains ions or through a molten ionic compound. (20.7)

Electrolysis Cell: An apparatus for electrolysis. (20.7)

Electrolyte: A compound that conducts electricity either in solution or in the molten state. (5.2)

Electrolytic Cell: See *Electrolysis Cell.*

Electrolytic Conduction: The transport of electrical charge by ions. (20.1)

Electromagnetic Radiation: (See *Electromagnetic Wave*)

Electromagnetic Spectrum: The distribution of frequencies of electromagneticradiation among various types of such radiation—microwave, infrared, visible, ultraviolet, X rays, and gamma rays. (8.1)

Electromagnetic Wave (Electromagnetic Radiation): The successive series of oscillations in the strengths of electrical and magnetic fields associated with light, microwaves, gamma rays, ultraviolet rays, infrared rays, and the like. (8.1)

Electron (e^- or ${}_{-1}^{0}e$): (a) A subatomic particle with a charge of 1– and mass of 0.0005486 u (9.109383×10^{-28} g) that occurs outside an atomic nucleus. The particle that moves when an electric current flows. (3.1) (b) A beta particle. (21.3)

Electron Affinity (EA): The energy change (usually expressed in kJ mol^{-1}) that occurs when an electron adds to an isolated gaseous atom or ion. (8.10)

Electron Capture: The capture by a nucleus of an orbital electron and that changes a proton into a neutron in the nucleus. (21.3)

Electron Cloud: Because of its wave properties, an electron's influence spreads out like a cloud around the nucleus. (8.9)

Electron Configuration: The distribution of electrons in an atom's orbitals. (8.7)

Electron Density: The concentration of the electron's charge within a given volume. (8.9)

Electron Domain: A region around an atom where one or more electron pairs are concentrated and which influences the shape of a molecule. (10.2)

Electron Domain Model: See *Valence Shell Electron Pair Repulsion Model.*

Electron Pair Bond: A covalent bond. (9.5)

Electron Spin: The spinning of an electron about its axis that is believed to occur because the electron behaves as a tiny magnet. (8.6)

Electron Volt (eV): The energy an electron receives when it is accelerated under the influence of 1 V and equal to 1.6×10^{-19} J. (29.3)

Electronegativity: The relative ability of an atom to attract electron density toward itself when joined to another atom by a covalent bond. (9.7)

Electronic Structure: The distribution of electrons in an atom's orbitals. (8.7)

Electroplating: Depositing a thin metallic coating on an object by electrolysis. (20.9)

Element: A substance in which all of the atoms have the same atomic number.

A substance that cannot be broken down by chemical reactions into anything that is both stable and simpler. (1.3, 3.1)

Elementary Process: One of the individual steps in the mechanism of a reaction. (14.8)

Elimination Reaction: The loss of a small molecule from a larger molecule as in the elimination of water from an alcohol. (23.3)

Emission Spectrum: See *Atomic Spectrum*.

Empirical Formula: A chemical formula that uses the smallest whole-number subscripts to give the proportions by atoms of the different elements present. (4.3)

Emulsion: A mixture of small globules of one immiscible liquid in another. (13.8)

Enantiomers: Stereoisomers whose molecular structures are related as an object to its mirror image but that cannot be superimposed. (22.4)

End Point: The moment in a titration when the indicator changes color and the titration is ended. (5.8, 17.9)

Endergonic: Descriptive of a change accompanied by an increase in free energy. (19.4)

Endothermic: Descriptive of a change in which a system's internal energy increases. (7.4)

Energy: Something that matter possesses by virtue of an ability to do work. (7.1)

Energy Band: Closely spaced energy levels in materials that can be described as a band of energy (10.9)

Energy Density: For a galvanic cell, the ratio of the energy available to the volume of the cell. (20.6)

Energy Level: A particular energy an electron can have in an atom or a molecule. (8.3)

English System: Old system of weights and measures that includes such units as pounds, ounces, gallons and miles. (2.2)

Enthalpy (*H*): The heat content of a system. (7.6, 19.1)

Enthalpy Change (ΔH): The difference in enthalpy between the initial state and the final state for some change. (7.6, 19.1)

Enthalpy Diagram: A graphical depiction of enthalpy changes following different paths from reactants to products. (7.8)

Enthalpy of Solution: See *Heat of Solution*.

Entropy (*S*): A thermodynamic quantity related to the number of equivalent ways the energy of a system can be distributed. The greater this number, the more probable is the state and the higher is the entropy. (19.3)

Entropy Change (ΔS): The difference in entropy between the initial state and the final state for some change. (19.4)

Enzyme: A catalyst in a living system and that consists of a protein. (23.6)

Equation of State of an Ideal Gas: See *Gas Law, Ideal.*

Equatorial Bond: A covalent bond located in the plane perpendicular to the long axis of a trigonal bipyramidal molecule. (10.1)

Equilibrium: See *Dynamic Equilibrium.*

Equilibrium Constant, *K*: The value that the mass action expression has when the system is at equilibrium. (15.2)

Equilibrium Law: The mathematical equation for a particular equilibrium system that sets the mass action expression equal to the equilibrium constant. (15.2)

Equilibrium Vapor Pressure of a Liquid: The pressure exerted by a vapor in equilibrium with its liquid state. (12.5)

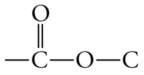
Equilibrium Vapor Pressure of a Solid: The pressure exerted by a vapor in equilibrium with its solid state. (12.5)

Equivalence: A relationship between two quantities expressed in different units. (2.4)

Equivalence Point: The moment in a titration when the number of equivalents of the reactant added from a buret equals the number of equivalents of another reactant in the receiving flask. (17.9)

Error in a Measurement: The difference between a measurement and the "true" value we are trying to measure. (2.3)

Ester: An organic compound whose molecules have the ester group. (23.3)



$$-\overset{\overset{\displaystyle O}{\|}}{C}-O-C$$

ester group

Ether: An organic compound in whose molecules two hydrocarbon groups are joined to an oxygen. (23.3)

Ethyl Group: Alkyl group derived from ethane, $-CH_2CH_3$ (23.2)

Evaporation: Change of state from a liquid to a vapor. (12.3)

Exact Number: A number obtained by a direct count or that results by a definition; and that is considered to have an infinite number of significant figures. (2.3)

Excess Reactant: The reactant left over once the limiting reactant is used up. (4.5)

Excited State: A term describing an atom or molecule where all of the electrons are not in their lowest possible energy levels. (8.2)

Exergonic: Descriptive of a change accompanied by a decrease in free energy. (19.4)

Exothermic: Descriptive of a change in which energy leaves a system and enters the surroundings. (7.4)

Expansion Work: See *Pressure–Volume Work.*

Exponential Notation: See *Scientific Notation.*

Extensive Property: A property of an object that is described by a physical quantity whose magnitude is proportional to the size or amount of the object (e.g., mass or volume). (2.1)

F

Face-Centered Cubic (fcc) Unit Cell: A unit cell having identical atoms, molecules, or ions at the corners of a cube and also in the center of each face of the cube. (12.11)

Factor-Label Method: See *Dimensional Analysis*

Fahrenheit Scale: A temperature scale on which water freezes at 32 °F and boils at 212 °F (at 1 atm) and between which points there are 180 degree divisions called Fahrenheit degrees. (2.2)

Family of Elements: See *Group.*

Faraday ($\mathscr{F}$): One mole of electrons; 9.65×10^4 coulombs. (20.4)

Faraday Constant ($\mathscr{F}$): 9.65×10^4 coulombs/mol e^-. (20.4)

Fatty Acid: One of several long-chain carboxylic acids produced by the hydrolysis (digestion) of a lipid. (23.6)

Film Dosimeter: A device used by people working with radioactive isotopes that records doses of atomic radiation by the darkening of photographic film. (21.6)

First Law of Thermodynamics: A formal statement of the law of conservation of energy. $\Delta E = q + w$. (7.5, 19.1)

First-Order Reaction: A reaction with a rate law in which rate $= k[A]^1$, where A is a reactant. (14.4)

Fissile Isotope: An isotope capable of undergoing fission following neutron capture. (21.8)

Fission: The breaking apart of atomic nuclei into smaller nuclei accompanied by the release of energy, and the source of energy in nuclear reactors. (21.2, 21.8)

Force: Anything that can cause an object to change its motion or direction.

Formal Charge: The apparent charge on an atom in a molecule or polyatomic ion as calculated by a set of rules. (9.8)

Formation Constant (K_{form}): The equilibrium constant for an equilibrium involving the formation of a complex ion. Also called the stability constant. (18.4)

Formula: See *Chemical Formula.*

Formula Mass: The sum of the atomic masses (in u) of all of the atoms represented in a chemical formula. Often used with units of g mol^{-1} to represent masses of ionic substances. (4.1) See also *Molar Mass.*

Formula Unit: A particle that has the composition given by the chemical formula. (3.4)

Forward Reaction: In a chemical equation, the reaction as read from left to right. (5.3, 15.1)

Fossil Fuels: Coal, oil, and natural gas.

Free Element: An element that is not combined with another element in a compound. (1.5)

Free Energy: See *Gibbs Free Energy* or *Standard Free Energy Change*

Free Energy Diagram: A plot of the changes in free energy for a multicomponent system versus the composition. (19.8)

Free Radical: An atom, molecule, or ion that has one or more unpaired electrons. (Chemistry Outside the Classroom 14.1, 21.6)

Freezing Point Depression: A colligative property of a liquid solution by which the freezing point of the solution is lower than that of the pure solvent. (13.7)

Frequency (ν): The number of cycles per second of electromagnetic radiation. (8.1)

Frequency Factor: The proportionality constant, A, in the Arrhenius equation. (14.7)

Fuel: Commonly one component of a combustion reaction; specifically the reducing agent. (7.9)

Fuel Cell: An electrochemical cell in which electricity is generated from the redox reactions of common fuels. (20.6)

Fullerene: An allotrope of carbon made of an extended joining together of five- and six-membered rings of carbon atoms. (10.10)

Functional Group: The group of atoms of an organic molecule that enters into a characteristic set of reactions that are independent of the rest of the molecule. (9.6)

Fusion: (a) Melting. (12.4) (b) The formation of atomic nuclei by the joining together of the nuclei of lighter atoms. (21.2, 21.8)

G

G: See *Gibbs Free Energy.*

ΔG: See *Gibbs Free Energy Change.*

$\Delta G°$: See *Standard Free Energy Change.*

$\Delta G_f°$: See *Standard Free Energy of Formation.*

Galvanic Cell: An electrochemical cell in which a spontaneous redox reaction produces electricity. (20.1)

Gamma Radiation: Electromagnetic radiation with wavelengths in the range of 1 Å or less (the shortest wavelengths of the spectrum). (20.3)

Gas: One of the states of matter. A gas consists of rapidly moving widely spaced atomic or molecular sized particles. (2.1)

Gas Constant, Universal (R): $R = 0.0821$ liter atm mol^{-1} K^{-1} or $R = 8.314$ J mol^{-1} K^{-1} (11.5)

Gas Law, Combined: For a given mass of gas, the product of its pressure and volume divided by its Kelvin temperature is a constant. (11.3)

$$PV/T = \text{a constant}$$

Gas Law, Ideal: $PV = nRT$. (11.5)

Gay-Lussac's Law: See *Pressure–Temperature Law.*

Geiger Counter: A device that detects beta and gamma radiation. (21.6)

Genetic Code: The correlation of codons with amino acids. (23.7)

Geometric Isomer: One of a set of isomers that differ only in geometry. (22.4, 23.2)

Geometric Isomerism: The existence of isomers whose molecules have identical atomic organizations but different geometries; cis-trans isomers. (22.4, 23.2)

Gibbs Free Energy (G): A thermodynamic quantity that relates enthalpy (H), entropy (S), and temperature (T) by the equation: (19.4)

$$G = H - TS$$

Gibbs Free Energy Change (ΔG): The difference given by: (19.4)

$$\Delta G = \Delta H - T\Delta S$$

Glass: Any amorphous solid. (12.11)

Global climate change: A term used to describe the overall effect of man-made and natural substances in the atmosphere that may cause heating or cooling of the Earth. (11.9)

Glycogen: A polysaccharide that animals use to store glucose units for energy. (23.6)

Graham's Law: See *Effusion, Law of.*

Gram (g): 0.001 kg. (2.2)

Graphene: A sheet of graphite, one atom thick. (10.10)

Graphite: The most stable allotrope of carbon, consisting of layers of joined six-membered rings of carbon atoms. (10.10)

Gray (Gy): The SI unit of radiation absorbed dose. (21.6)

$$1\ \text{Gy} = 1\ \text{J kg}^{-1}$$

Greenhouse Effect: The retention of solar energy made possible by the ability of the greenhouse gases (e.g., CO_2, CH_4, H_2O, and the chlorofluorocarbons) to absorb outgoing radiation and reradiate some of it back to earth. (11.9)

Ground State: The lowest energy state of an atom or molecule. (8.3)

Group: A vertical column of elements in the periodic table. (3.2)

H

ΔH: See *Enthalpy Change.*

ΔH_{atom}: See *Atomization Energy.*

ΔH_c: See *Heat of Combustion.*

$\Delta H°$: See *Standard Heat of Reaction.*

$\Delta H_f°$: See *Standard Heat of Formation.*

ΔH_{fusion}: See *Molar Heat of Fusion.*

ΔH_{soln}: See *Heat of Solution.*

$\Delta H_{\text{sublimation}}$: See *Molar Heat of Sublimation.*

$\Delta H_{\text{vaporization}}$: See *Molar Heat of Vaporization.*

Half-Cell: That part of a galvanic cell in which either oxidation or reduction takes place. (20.1)

Half-Life ($t_{1/2}$): The time required for a reactant concentration or the mass of a radionuclide to be reduced by half. (14.4)

Half-Reaction: A hypothetical reaction that constitutes exclusively either the oxidation or the reduction half of a redox reaction and all species taking part in the change are given together with enough electrons to give the correct electrical balance. (6.2)

Hall–Héroult Process: A method for manufacturing aluminum by the electrolysis of aluminum oxide in molten cryolite. (20.8)

Halogen Family: Group 7A in the periodic table—fluorine, chlorine, bromine, iodine, and astatine. (3.2)

Hard Water: Water with dissolved Mg^{2+}, Ca^{2+}, Fe^{2+}, or Fe^{3+} ions at a concentration high enough (above 25 mg L^{-1}) to interfere with the use of soap. (Chemistry Outside the Classroom 5.2)

Heat: Energy that flows from a hot object to a cold object as a result of their difference in temperature. (7.1)

Heat Capacity: The quantity of heat needed to raise the temperature of an object by 1 °C. (7.3)

Heat of Combustion (ΔH_c): The heat evolved in the combustion of a substance. (7.6)

Heat of Formation, Standard: See *Standard Heat of Formation.*

Heat of Reaction: The heat exchanged between a system and its surroundings when a chemical change occurs in the system. (7.5)

Heat of Reaction at Constant Pressure (q_p): The heat of a reaction in an open system, ΔH. (7.5, 19.1)

Heat of Reaction at Constant Volume (q_v): The heat of a reaction in a sealed vessel, like a bomb calorimeter, ΔE. (7.6)

Heat of Reaction, Standard: See *Standard Heat of Reaction.*

Heat of Solution (ΔH_{soln}): The energy exchanged between the system and its surroundings when one mole of a solute dissolves in a solvent to make a dilute solution. (13.2)

Heating Curve: A graph showing how the temperature of a substance changes as heat is added to it at a constant rate as the substance undergoes changes in its physical state. (12.7)

Henderson–Hasselbalch Equation:

$$\mathrm{pH} = \mathrm{p}K_\mathrm{a} + \log\frac{[A^-]_\mathrm{initial}}{[\mathrm{H}A]_\mathrm{initial}} \text{ or}$$

$$\mathrm{pH} = \mathrm{p}K_\mathrm{a} + \log\frac{[\mathrm{salt}]}{[\mathrm{acid}]} \quad (16.5) \qquad (17.7)$$

Henry's Law: See *Pressure–Solubility Law*.

Hertz (Hz): 1 cycle s^{-1}; the SI unit of frequency. (8.1)

Hess's Law: For any reaction that can be written in steps, the standard heat of reaction is the same as the sum of the standard heats of reaction for the steps. (7.8)

Hess's Law Equation: For the change,

$$aA + bB + \cdots \longrightarrow nN + mM + \cdots \quad (6.8)$$

$$\Delta H^\circ = \begin{pmatrix}\text{sum of } \Delta H_\mathrm{f}^\circ \text{ of all} \\ \text{of the products}\end{pmatrix} - \begin{pmatrix}\text{sum of } \Delta H_\mathrm{f}^\circ \text{ of all} \\ \text{of the reactants}\end{pmatrix} \quad (7.9)$$

Heterocyclic Rings: Molecular rings that include one or more multivalent atoms other than carbon. (23.1)

Heterogeneous Catalyst: A catalyst that is in a different phase than the reactants and onto whose surface the reactant molecules are adsorbed and where they react. (14.9)

Heterogeneous Equilibrium: An equilibrium involving more than one phase. (15.4)

Heterogeneous Mixture: A mixture that has two or more phases with different properties. (1.3)

Heterogeneous Reaction: A reaction in which not all of the chemical species are in the same phase. (14.1, 15.4)

Heteronuclear Molecule: A molecule in which not all atoms are of the same element. (10.7)

Hexagonal Closest Packing (hcp): Efficient packing of spheres with an A-B-A-B-. . . alternating stacking of layers of spheres. (12.11)

High-Spin Complex: A complex ion or coordination compound in which there is the maximum number of unpaired electrons. (22.5)

Hole: An electron deficient site in a semiconductor. A positive charge carrier. (20.6)

Homogeneous Catalyst: A catalyst that is in the same phase as the reactants. (14.9)

Homogeneous Equilibrium: An equilibrium system in which all components are in the same phase. (15.2)

Homogeneous Mixture: A mixture that has only one phase and that has uniform properties throughout; a solution. (1.3)

Homogeneous Reaction: A reaction in which all of the chemical species are in the same phase. (14.1, 15.2)

Homonuclear Diatomic Molecule: A diatomic molecule in which both atoms are of the same element. (10.7)

Hund's Rule: Electrons that occupy orbitals of equal energy are distributed with unpaired spins as much as possible among all such orbitals. (8.7)

Hybrid Atomic Orbitals: Orbitals formed by mixing two or more of the basic atomic orbitals of an atom and that make possible more effective overlaps with the orbitals of adjacent atoms than do ordinary atomic orbitals. (10.5)

Hydrate: A compound that contains molecules of water in a definite ratio to other components. (1.5)

Hydrated Ion: An ion surrounded by a cage of water molecules that are attracted by the charge on the ion. (5.2)

Hydration: The development in an aqueous solution of a cage of water molecules about ions or polar molecules of the solute. (13.1)

Hydration Energy: The enthalpy change associated with the hydration of gaseous ions or molecules as they dissolve in water. (13.2)

Hydride: (a) A binary compound of hydrogen. (3.6) (b) A compound containing the hydride ion (H^-).

Hydrocarbon: An organic compound whose molecules consist entirely of carbon and hydrogen atoms. (3.6, 23.2)

Hydrogen Bonding: An extra strong dipole–dipole attraction between a hydrogen bound covalently to nitrogen, oxygen, or fluorine and another nitrogen, oxygen, or fluorine atom. (12.2)

Hydrogen Electrode: The standard of comparison for reduction potentials and for which $E^\circ_{\mathrm{H^+}}$ has a value of 0.00 V at 25 °C, when $P_{\mathrm{H_2}} = 1$ atm and $[\mathrm{H^+}] =$ 1 M in the reversible half-cell reaction: $2\mathrm{H}^+(aq) + 2e^- \rightleftharpoons \mathrm{H}_2(g)$. (20.2)

Hydrolysis: A reaction with water (16.6, 17.6)

Hydrometer: A device for measuring specific gravity. (20.6)

Hydronium Ion: $\mathrm{H_3O^+}$. (5.3)

Hydrophilic: Miscible with water, literally, "water loving." (13.8, 23.6)

Hydrophilic Group: A polar molecular unit capable of having dipole–dipole attractions or hydrogen bonds with water molecules. (23.6)

Hydrophobic. Not miscible with water, literally, "afraid of water." (13.8, 23.6)

Hydrophobic Group: A nonpolar molecular unit with no affinity for water. (22.7)

Hypertonic Solution: A solution that has a higher osmotic pressure than cellular fluids. (13.7)

Hypothesis: A tentative explanation of the results of experiments. (1.2)

Hypotonic Solution: A solution that has a lower osmotic pressure than cellular fluids. (13.7)

Hypoxia: Condition of natural water where there is not dissolved oxygen to support aquatic life. (13.3)

I

Ideal Gas: A hypothetical gas that obeys the gas laws exactly. (11.3)

Ideal Gas Law: $PV = nRT$. (11.5)

Ideal Solution: A hypothetical solution that would obey the vapor pressure–concentration law (Raoult's law) exactly. (13.2)

Immiscible: Mutually insoluble. Usually used to describe liquids that are insoluble in each other. (13.1)

Incompressible: Incapable of losing volume under increasing pressure. (12.3)

Independent Variable: The experimental variable of a pair of variables whose value is first selected and from which the value of the dependent variable then results.

Indicator: A chemical put in a solution being titrated and whose change in color signals the end point. (5.8, 17.9)

Induced Dipole: A dipole created when the electron cloud of an atom or a molecule is distorted by a neighboring dipole or by an ion. (12.2)

Inert Gas: See *Noble Gases*

Initiation Step: The step in a chain reaction that produces reactive species that can start chain propagation steps. (Chemistry Outside the Classroom 14.1)

Inner Transition Elements: Members of the two long rows of elements below the main body of the periodic table—elements 58–71 and elements 90–103. (3.2)

Inorganic Compound: A compound made from any elements except those compounds of carbon classified as organic compounds. (3.5)

Instability Constant (K_{inst}): The reciprocal of the formation constant for an equilibrium in which a complex ion forms. (18.4)

Instantaneous Dipole: A momentary dipole in an atom, ion, or molecule caused by the erratic movement of electrons. (12.2)

Instantaneous Rate: The rate of reaction at any particular moment during a reaction. (14.2)

Integrated Rate Law: A rate law that relates concentration versus time. (14.4)

Intensive Property: A property whose physical magnitude is independent of the size of the sample, such as density or temperature. (2.1)

Intercalation: The insertion of small atoms or ions between layers in a crystal such as graphite. (20.6)

Interference Fringes: Pattern of light produced by waves that undergo diffraction. (8.4)

Intermolecular Forces (Intermolecular Attractions): Attractions *between* neighboring molecules. (12.2)

Internal Energy (*E*): The sum of all of the kinetic energies and potential energies of the particles within a system. (7.2, 19.1)

Internal Energy Change (ΔE): The difference in internal energy between the initial state and the final state for some change. (7.2)

International System of Units (SI): The successor to the metric system of measurements that retains most of the units of the metric system and their decimal relationships but employs new reference standards. (2.2)

Intramolecular Forces: Forces of attraction within molecules; chemical bonds. (11.2)

Inverse Square Law: The intensity of a radiation is inversely proportional to the square of the distance from its source. (21.6)

Ion: An electrically charged particle on the atomic or molecular scale of size. (3.4)

Ion–Dipole Attraction: The attraction between an ion and the charged end of a polar molecule. (12.2)

Ion–Electron Method: A method for balancing redox reactions that uses half-reactions. (6.2)

Ion–Induced Dipole Attraction: Attraction between an ion and a dipole induced in a neighboring molecule. (12.2)

Ion Pair: A more or less loosely associated pair of ions in a solution. (13.7)

Ion Product: The mass action expression for the solubility equilibrium involving the ions of a salt and equal to the product of the molar concentrations of the ions, each concentration raised to a power that equals the number of ions obtained from one formula unit of the salt. (18.1)

Ion Product Constant of Water (K_w): $K_w = [H^+][OH^-]$ (17.1)

Ionic Bond: The attractions between ions that hold them together in ionic compounds. (9.2)

Ionic Character: The extent to which a covalent bond has a dipole moment and is polarized. (9.7)

Ionic Compound: A compound consisting of positive and negative ions. (3.4)

Ionic Crystal: A crystal that has ions located at the lattice points. (12.13)

Ionic Equation: A chemical equation in which soluble strong electrolytes are written in dissociated or ionized form. (5.2)

Ionic Reaction: A chemical reaction in which ions are involved. (5.2)

Ionization Energy (IE): The energy needed to remove an electron from an isolated, gaseous atom, ion, or molecule (usually given in units of kJ mol^{-1}). (8.10)

Ionization Reaction: A reaction of chemical particles that produces ions. (5.3)

Ionizing Radiation: Any high-energy radiation—X rays, gamma rays, or radiations from radionuclides—that generates ions as it passes through matter. (22.6)

Isolated System: A system that cannot exchange matter or energy with its surroundings. (7.3)

Isomer: One of a set of compounds that have identical molecular formulas but different structures. (22.4)

Isomerism: The existence of sets of isomers. (9.6, 22.4)

Isopropyl Group: Alkyl group derived from propane, $—CH(CH_3)_2$ (23.2)

Isothermal: A system where the temperature remains unchanged. (19.1)

Isotonic Solution: A solution that has the same osmotic pressure as cellular fluids. (12.8)

Isotopes: Atoms of the same element with different atomic masses. Atoms of the same element with different numbers of neutrons in their nuclei. (3.1)

IUPAC Rules: The formal rules for naming substances as developed by the International Union of Pure and Applied Chemistry. (3.5, 23.2)

J

Joule (J): The SI unit of energy. (7.1)
$1\ J = 1\ kg\ m^2\ s^{-2}$
$4.184\ J = 1$ cal (exactly)

K

K: See *Kelvin.*

K_a: See *Acid Ionization Constant.*

K_b: See *Base Ionization Constant.*

K_{form}: See *Formation Constant.*

K_{inst}: See *Instability Constant.*

K_{sp}: See *Solubility Product Constant.*

K_{spa}: See *Acid Solubility Product.*

K_w: See *Ion Product Constant of Water.*

K-Capture: See *Electron Capture.*

Kelvin (K): One degree on the Kelvin scale of temperature and identical in size to the Celsius degree. (2.2)

Kelvin Scale: The temperature scale on which water freezes at 273.15 K and boils at 373.15 K and that has 100 degree divisions called kelvins between these points. K = °C + 273.15. (2.2)

Ketone: An organic compound whose molecules have the carbonyl group ($C{=}O$) flanked by hydrocarbon groups. (9.6)

Kilocalorie (kcal): 1000 cal. (7.1)

Kilogram (kg): The base unit for mass in the SI and equal to the mass of a cylinder of platinum–iridium alloy kept by the International Bureau of Weights and Measures at Sevres, France. 1 kg = 1000 g. (2.2)

Kilojoule (kJ): 1000 J. (7.1)

Kinetic Energy (KE): Energy of motion. $KE = (1/2)mv^2$. (7.1)

Kinetic Molecular Theory: Molecules of a substance are in constant motion with a distribution of kinetic energies at a given temperature. The average kinetic energy of the molecules is proportional to the Kelvin temperature. (7.2)

Kinetic Molecular Theory of Gases: A set of postulates used to explain the gas laws. A gas consists of an extremely large number of very tiny, very hard particles in constant, random motion. They have negligible volume and, between collisions, experience no forces between themselves. (11.7)

L

Lanthanide Elements: Elements 58–71. (3.2)

Lattice: A symmetrical pattern of points arranged with constant repeat distances along lines oriented at constant angles. (12.11)

Lattice Energy: Energy released by the imaginary process in which isolated ions come together to form a crystal of an ionic compound. (9.2)

Law: A description of behavior (and not an *explanation* of behavior) based on the results of many experiments. (1.2)

Law of Combining Volumes: When gases react at the same temperature and pressure, their combining volumes are in ratios of simple whole numbers. (11.4)

Law of Conservation of Energy: The energy of the universe is constant; it can be neither created nor destroyed but only transferred and transformed. (7.1)

Law of Conservation of Mass: No detectable gain or loss in mass occurs in chemical reactions. Mass is conserved. (1.4)

Law of Conservation of Mass–Energy: The sum of all the mass in the universe and of all of the energy, expressed as an equivalent in mass (calculated by the Einstein equation), is a constant. (22.1)

Law of Definite Proportions: In a given chemical compound, the elements are always combined in the same proportion by mass. (1.4)

Law of Gas Effusion: See *Effusion, Law of.*

Law of Multiple Proportions: Whenever two elements form more than one compound, the different masses of one element that combine with the same mass of the other are in a ratio of small whole numbers. (2.4)

Law of Partial Pressures: See *Partial Pressures, Dalton's Law of.*

Law of Radioactive Decay:

$$\text{Activity} = -\frac{\Delta N}{\Delta t} = kN,$$

where ΔN is the change in the number of radioactive nuclei during the time span Δt, and k is the decay constant. (21.6)

Le Châtelier's Principle: When a system that is in dynamic equilibrium is subjected to a disturbance that upsets the equilibrium, the system undergoes a change that counteracts the disturbance and, if possible, restores the equilibrium. (15.6)

Lead Storage Battery: A galvanic cell of about 2 V involving lead and lead(IV) oxide in sulfuric acid. (20.6)

Leclanché Cell: See *Zinc–Manganese Dioxide Cell.*

Lewis Acid: An electron-pair acceptor. (16.4)

Lewis Base: An electron-pair donor. (16.4)

Lewis Structure (Lewis Formula): A structural formula drawn with Lewis symbols and that uses dots and dashes to show the valence electrons and shared pairs of electrons. (9.5)

Lewis Symbol: The symbol of an element that includes dots to represent the valence electrons of an atom of the element. (9.4)

Ligand: A molecule or an anion that can bind to a metal ion to form a complex. (18.4, 22.1)

Light-Emitting Diode (LED): A semiconductor device where a small applied voltage will eject visible photons. (10.9)

Like Dissolves Like Rule: Strongly polar and ionic solutes tend to dissolve in polar solvents and nonpolar solutes tend to dissolve in nonpolar solvents. (13.1)

Limiting Reactant: The reactant that determines how much product can form when nonstoichiometric amounts of reactants are used. (4.5)

Line Spectrum: An atomic spectrum. So named because the light emitted by an atom and focused through a narrow slit yields a series of lines when projected on a screen. (8.1)

Linear Molecule: A molecule all of whose atoms lie on a straight line. (10.1, 10.2)

Lipid: Any substance found in plants or animals that can be dissolved in nonpolar solvents. (23.6)

Liquid: One of the states of matter. A liquid consists of tightly packed atomic or molecular sized particles that can move past each other. (2.1)

Liter (L): 1 dm^3. 1 L = 1000 mL = 1000 cm^3. (2.2)

Lithium Ion Cell: A cell in which lithium ions are transferred between the electrodes through an electrolyte, while electrons travel through the external circuit. (20.6)

Lithium–Manganese Dioxide Battery: A battery that uses metallic lithium as the anode and manganese dioxide as the cathode. (20.6)

Localized Bond: A covalent bond in which the bonding pair of electrons is localized between two nuclei.

London Forces (Dispersion Forces): Weak attractive forces caused by instantaneous dipole–induced dipole attractions. (12.2)

Lone Pair: A pair of electrons in the valence shell of an atom that is not shared with another atom. An unshared pair of electrons. (10.2)

Low-Spin Complex: A coordination compound or a complex ion with electrons paired as much as possible in the lower energy set of *d* orbitals. (22.5)

M

Macromolecule: A molecule whose molecular mass is very large. (23.5)

Macroscopic: A scale that includes masses in the range of 1 to 1000 g or the equivalent. Also considered the laboratory scale. (1.2)

Magic Numbers: The numbers 2, 8, 20, 28, 50, 82, and 126, numbers whose significance in nuclear science is that a nuclide in which the number of protons or neutrons equals a magic number has nuclei that are relatively more stable than those of other nuclides nearby in the band of stability. (21.4)

Magnetic Quantum Number (m_ℓ): A quantum number that can have values from zero to $N - 1$. (8.5)

Main Group Elements: Elements in any of the A groups in the periodic table. (3.2)

Main Reaction: The desired reaction between the reactants as opposed to competing reactions that give by-products. (4.6)

Malleability: A metal's ability to be hammered or rolled into thin sheets. (3.3)

Manometer: A device for measuring the pressure within a closed system. The two types—*closed end* and *open end*—differ according to whether the operating fluid (e.g., mercury) is exposed at one end to the atmosphere. (11.2)

Mass: A measure of the amount of matter that there is in a given sample. (1.3)

Mass Action Expression: A fraction in which the numerator is the product of the molar concentrations of the products, each raised to a power equal to its coefficient in the equilibrium equation, and the denominator is the product of the molar concentrations of the reactants, each also raised to the power that equals its coefficient in the equation. (For gaseous reactions, partial pressures can be used in place of molar concentrations.) (15.2)

Mass Defect: For a given isotope, it is the mass that changed into energy as the nucleons gathered to form the nucleus, this energy being released from the system. (21.2)

Mass Fraction: The ratio of the mass of one component of a mixture to the total mass of that same mixture. (13.5)

Mass Number: The numerical sum of the protons and neutrons in an atom of a given isotope. (3.1)

Matter: Anything that has mass and occupies space. (1.3)

Mean: The sum of N numerical values divided by N; the average. (2.3)

Measurement: A numerical observation. (2.2)

Mechanism of a Reaction: The series of individual steps (called elementary processes) in a chemical reaction that gives the net, overall change. (14.8)

Melting Point: The temperature at which a substance melts; the temperature at which a solid is in equilibrium with its liquid state. (12.4)

Meniscus: The interface between a liquid and a gas.

Metal: An element or an alloy that is a good conductor of electricity, that has a shiny surface, and that is malleable and ductile; an element that normally forms positive ions and has an oxide that is basic. (3.3)

Metallic Conduction: Conduction of electrical charge by the movement of electrons. (20.1)

Metallic Crystal: A solid having positive ions at the lattice positions that are attracted to a "sea of electrons" that extends throughout the entire crystal. (12.13)

Metalloids: Elements with properties that lie between those of metals and nonmetals, and that are found in the periodic table around the diagonal line running from boron (B) to astatine (At). (3.3)

Metathesis Reaction: See *Double Replacement Reaction.*

Meter (m): The SI base unit for length. (2.2)

Methyl Group: Alkyl group derived from methane, $—CH_3$

Metric Units: A decimal system of units for physical quantities taken over by the SI. (2.2) See also *International System of Units.*

Micelle: A structure formed from molecules that have a hydrophobic and hydrophilic end. The result is a circular or spherical structure with the molecules forming a rudimentary membrane. (13.8)

Millibar: 1 mb $= 10^{-3}$ bar. (11.2)

Milliliter (mL): 0.001 L. 1000 mL = 1 L. (2.2)

Millimeter (mm): 0.001 m. 1000 mm = 1 m. (2.2)

Millimeter of Mercury (mm Hg): A unit of measurement that is proportional to pressure; equal to 1/760 atm. 760 mm Hg = 1 atm. 1 mm Hg = 1 torr. (11.2)

Miscible: Mutually soluble. (13.1)

Mixture: Any matter consisting of two or more substances physically combined in no particular proportion by mass. (1.3)

MO Theory: See *Molecular Orbital Theory.*

Model, Theoretical: A picture or a mental construction derived from a set of ideas and assumptions that are imagined to be true because they can be used to explain certain observations and measurements (e.g., the model of an ideal gas). (1.2)

Mol L^{-1} s^{-1}: See *Rate of Reaction*

Molal Boiling Point Elevation Constant (K_b): The number of degrees (°C) per unit of molal concentration that a boiling point of a solution is higher than that of the pure solvent. (13.7)

Molal Concentration (m): The number of moles of solute in 1000 g of solvent. (13.5)

Molal Freezing Point Depression Constant (K_f): The number of degrees (°C) per unit of molal concentration that a freezing point of a solution is lower than that of the pure solvent. (13.7)

Molality: The molal concentration. (13.5)

Molar Concentration (M): The number of moles of solute per liter of solution. The molarity of a solution. (5.6)

Molar Enthalpy of Solution: See *Heat of Solution.*

Molar Heat Capacity: The heat that can raise the temperature of 1 mol of a substance by 1 °C; the heat capacity per mole. (7.3)

Molar Heat of Fusion, ΔH_{fusion}: The heat absorbed when 1 mol of a solid melts to give 1 mol of the liquid at constant temperature and pressure. (12.7)

Molar Heat of Sublimation, $\Delta H_{\text{sublimation}}$: The heat absorbed when 1 mol of a solid sublimes to give 1 mol of its vapor at constant temperature and pressure. (12.7)

Molar Heat of Vaporization, $\Delta H_{\text{vaporization}}$: The heat absorbed when 1 mol of a liquid changes to 1 mol of its vapor at constant-temperature and pressure. (12.7)

Molar Mass: The mass of one mole of a substance; the mass in grams equal to the sum of the atomic masses of the atoms in a substance, with units of g mol^{-1}. (4.1)

Molar Solubility: The number of moles of solute required to give 1 L of a saturated solution of the solute. (18.1)

Molar Volume, Standard: The volume of 1 mol of a gas at STP; 22.4 L mol^{-1}. (11.4)

Molarity: See *Molar Concentration.*

Mole (mol): The SI unit for amount of substance; the formula mass in grams of an element or compound; an amount of a chemical substance that contains 6.022×10^{23} formula units. (4.1)

Mole Fraction: The ratio of the number of moles of one component of a mixture to the total number of moles of all components. (11.6)

Mole Percent (mol%): The mole fraction of a component expressed as a percent; mole fraction × 100%. (11.6, 13.5)

Molecular Compound: A compound consisting of electrically neutral molecules. (2.6)

Molecular Crystal: A crystal that has molecules or individual atoms at the lattice points. (12.13)

Molecular Equation: A chemical equation that gives the full formulas of all of the reactants and products and that is used to plan an actual experiment. (5.2)

Molecular Formula: A chemical formula that gives the actual composition of one molecule. (3.6, 4.3)

Molecular Kinetic Energy: The energy associated with the motions of and within molecules as they fly about, spinning and vibrating. (7.2)

Molecular Mass: The sum of the atomic masses (in u) of all of the atoms represented in a molecular chemical substance; also called the *molecular weight.* May be used with units of g mol^{-1}. (4.1) See also *Molar Mass.*

Molecular Orbital (MO): An orbital that extends over two or more atomic nuclei. (10.7)

Molecular Orbital Theory (MO Theory): A theory about covalent bonds that views a molecule as a collection of positive nuclei surrounded by electrons distributed among a set of bonding, antibonding, and nonbonding orbitals of different energies. (10.4)

Molecular Weight: See *Molecular Mass.*

Molecule: A neutral particle composed of two or more atoms combined in a definite ratio of whole numbers. (1.5, 3.6)

Monatomic: A particle consisting of just one atom. (3.5)

Monoclinic Sulfur: An allotrope of sulfur. (10.10)

Monodentate Ligand: A ligand that can attach itself to a metal ion by only one atom. (22.1)

Monomer: A substance of relatively low formula mass that is used to make a polymer. (23.5)

Monoprotic Acid: An acid that can furnish one H^+ per molecule. (5.3)

Monosaccharide: A carbohydrate that cannot be hydrolyzed. (23.6)

N

n-type Semiconductor: A semiconductor that carries electrical charge by means of electron movement. (10.9)

Nanotechnology: The study and use of unique properties of matter that has dimensions measured in nanometers. (1.6)

Negative Charge: A type of electrical charge possessed by certain particles such as the electron. A negative charge is attracted by a positive charge and is repelled by another negative charge. (3.1)

Negative Charge Carrier: In a semiconductor, the electrons are considered to be negative charge carriers. (20.6)

Nernst Equation: An equation relating cell potential and concentration. (20.5)

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{RT}{n\mathcal{F}}\ln Q$$

Net Ionic Equation: A chemical equation that shows only the reacting ions and from which spectator ions have been omitted. It is balanced when both atoms and electrical charge balance. (5.2)

Network Solid: See *Covalent Crystal.*

Neutral Solution: A solution in which $[H^+] = [OH^-]$. (17.1)

Neutralization, Acid–Base: See *Acid–Base Neutralization.*

Neutron: A subatomic particle with a charge of zero, a mass of 1.0086649 u (1.674927×10^{-24} g) and that exists in all atomic nuclei except those of the hydrogen-1 isotope. (3.1)

Neutron Activation Analysis: A technique to analyze for trace impurities in a sample by studying the frequencies and intensities of the gamma radiations they emit after they have been rendered radioactive by neutron bombardment of the sample. (21.7)

Neutron Emission: A nuclear reaction in which a neutron is ejected. (21.3)

Nicad Battery: A nickel–cadmium cell. (20.6)

Nickel–Cadmium Storage Cell: A galvanic cell of about 1.4 V involving the reaction of cadmium with nickel(IV) oxide. (20.6)

Nitrogen Family: Group 5A in the periodic table—nitrogen, phosphorus, arsenic, antimony, and bismuth. (3.2)

Noble Gases: Group 8A in the periodic table—helium, neon, argon, krypton, xenon, and radon. (3.2)

Noble Metals: The group of transition metals, including gold, silver and platinum, that have relatively low chemical reactivity. (9.7)

Nodal Plane: A plane that can be drawn to separate opposing lobes of *p*, *d*, and *f* orbitals. (8.9)

Node: A place where the amplitude or intensity of a wave is zero. (8.4)

Nomenclature: The names of substances and the rules for devising names. (3.5)

Nonbonding Domain: A region in the valence shell of an atom that holds an unshared pair of electrons and that influences the shape of a molecule. (10.2)

Nonbonding Molecular Orbital: A molecular orbital that has no net effect on the stability of a molecule when populated with electrons and that is localized on one atom in the molecule. (10.7)

Nonelectrolyte: A compound that in its molten state or in solution cannot conduct electricity. (5.2)

Nonlinear Molecule: A molecule in which the atoms do not lie in a straight line. (10.2)

Nonmetal: A nonductile, nonmalleable, nonconducting element that tends to form negative ions (if it forms them at all) far more readily than positive ions and whose oxide is likely to show acidic properties. (3.3)

Nonmetal Hydrides: Usually binary compounds that contain hydrogen and a nonmetal. (3.6)

Nonmetallic Element: See *Nonmetals*

Nonoxidizing Acid: An acid in which the anion is a poorer oxidizing agent than the hydrogen ion (e.g., HCl, H_2SO_4, H_3PO_4). (6.3)

Nonpolar Covalent Bond: A covalent bond in which the electron pair(s) are shared equally by the two atoms. (9.7)

Nonpolar Molecule: A molecule that has no net dipole moment. (9.3)

Nonvolatile: Descriptive of a substance with a high boiling point, a low vapor pressure. and that does not evaporate. (12.6)

Normal Boiling Point: The temperature at which the vapor pressure of a liquid equals 1 atm. (12.6)

Nuclear Binding Energy: See *Binding Energy, Nuclear.*

Nuclear Chain Reaction: A self-sustaining nuclear reaction. (21.8)

Nuclear Equation: A description of a nuclear reaction that uses the special symbols of isotopes, that describes some kind of nuclear transformation or disintegration, and that is balanced when the sums of the atomic numbers on either side of the arrow are equal and the sums of the mass numbers are also equal. (21.3)

Nuclear Fission: See *Fission.*

Nuclear Fusion: See *Fusion.*

Nuclear Radiation: Alpha, beta, or gamma radiation emitted by radioactive nuclei. (21.3)

Nuclear Reaction: A change in the composition or energy of the nuclei of isotopes accompanied by one or more events such as the radiation of nuclear particles or electromagnetic energy, transmutation, fission, or fusion. (13.4, 20.3)

Nucleic Acids: Polymers in living cells that store and translate genetic information and whose molecules hydrolyze to give a sugar unit (ribose from ribonucleic acid, RNA, or deoxyribose from deoxyribonucleic acid, DNA), a phosphate, and a set of four of the five nitrogen-containing, heterocyclic bases (adenine, thymine, guanine, cytosine, and uracil). (23.7)

Nucleon: A proton or a neutron. (3.1, 21.2)

Nucleus: The hard, dense core of an atom that holds the atom's protons and neutrons. (3.1)

Nylon 6,6: A polymer of a six-carbon dicarboxylic acid and a six-carbon diamine. (23.5)

O

Observation: A statement that accurately describes something we see, hear, taste, feel, or smell. (1.2)

Octahedral Molecule: A molecule in which a central atom is surrounded by six atoms located at the vertices of an imaginary octahedron. (10.1)

Octahedron: An eight-sided figure that can be envisioned as two square pyramids sharing the common square base. (10.1)

Octet (of Electrons): Eight electrons in the valence shell of an atom. (9.3)

Octet Rule: An atom tends to gain or lose electrons until its outer shell has eight electrons. (9.3, 9.5)

Odd–Even Rule: When the numbers of protons and neutrons in an atomic nucleus are both even, the isotope is more likely to be stable than when both numbers are odd. (21.4)

Open System: A system that can exchange both matter and energy with its surroundings. (7.3)

Open-End Manometer: See *Manometer.*

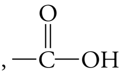
Optical Isomers: Stereoisomers other than geometric (cis–trans) isomers and that include substances that can rotate the plane of plane-polarized light. (22.4)

Orbital: An electron waveform with a particular energy and a unique set of values for the quantum numbers *n*, ℓ, and m_ℓ. (8.5)

Orbital Diagram: A diagram in which the electrons in an atom's orbitals are represented by arrows to indicate paired and unpaired spins. (8.7)

Order (of a Reaction): The sum of the exponents in the rate law is the *overall* order. Each exponent gives the order of the reaction with respect to a specific reactant. (14.3)

Organic Acid: An acid that contains the carboxyl group,



$-\overset{\overset{\displaystyle O}{\|}}{C}-OH$ (8.3, 9.6, 22.6)

Organic Chemistry: The study of the compounds of carbon that are not classified as inorganic. (3.6, 23.1)

Organic Compound: Any compound of carbon other than a carbonate, bicarbonate, cyanide, cyanate, carbide, or gaseous oxide. (3.5, 9.6)

Orthorhombic Sulfur: The most stable allotrope of sulfur, composed of S_8 rings. (10.10)

Osmosis: The passage of solvent molecules, but not those of solutes, through a semipermeable membrane; the limiting case of dialysis. (13.7)

Osmotic Membrane: A membrane that allows passage of solvent, but not solute particles. (13.7)

Osmotic Pressure: The back pressure that would have to be applied to prevent osmosis; one of the colligative properties. (13.7)

Outer Electrons: The electrons in the occupied shell with the largest principal quantum number. An atom's electrons in its valence shell. (8.8)

Outer Shell: The occupied shell in an atom having the highest principal quantum number (*n*). (8.8)

Overall Order of Reaction: The sum of the exponents on the concentration terms in a rate law. (14.3)

Overlap of Orbitals: A portion of two orbitals from different atoms that share the same space in a molecule. (10.4)

Oxidation: A change in which an oxidation number increases (becomes more positive). A loss of electrons. (6.1)

Oxidation Number: The charge that an atom in a molecule or ion would have if all of the electrons in its bonds belonged entirely to the more electronegative atoms; the oxidation state of an atom. (6.1)

Oxidation State: See *Oxidation Number*.

Oxidation–Reduction Reaction: A chemical reaction in which changes in oxidation numbers occur. (6.1)

Oxidizing Acid: An acid in which the anion is a stronger oxidizing agent than H^+ (e.g., $HClO_4$, HNO_3). (6.3)

Oxidizing Agent: The substance that causes oxidation and that is itself reduced. (6.1)

Oxoacid: An acid that contains oxygen besides hydrogen and another element (e.g., HNO_3, H_3PO_4, H_2SO_4). (5.4, 16.3)

Oxoanion: The anion of an oxoacid (e.g., ClO_4^-, SO_4^{2-}). (16.3)

Oxygen Family: Group 6A in the periodic table—oxygen, sulfur, selenium, tellurium, and polonium.

Ozone: A very reactive allotrope of oxygen with the formula O_3. (11.9)

Ozone Hole: The large decrease of stratospheric ozone at the Earth's poles at the end of winter each year; ascribed to the effect of chlorine compounds. (11.9)

P

p-n Junction: The surface where a p-type semiconductor and an n-type semiconductor meet. (10.9)

p-type Semiconductor: A semiconductor material with a deficit of electrons causing charge to be carried by positive charge carriers or "holes." (10.9)

Pairing Energy: The energy required to force two electrons to become paired and occupy the same orbital. (22.5)

Paramagnetism: The weak magnetism of a substance whose atoms, molecules, or ions have one or more unpaired electrons. (8.6)

Partial Charge: Charges at opposite ends of a dipole that are fractions of full 1+ or 1− charges. (9.7)

Partial Pressure: The pressure contributed by an individual gas to the total pressure of a gas mixture. (11.6)

Partial Pressure, Law of (Dalton's Law of Partial Pressures): The total pressure of a mixture of gases equals the sum of their partial pressures. (11.6)

Pascal (Pa): The SI unit of pressure equal to 1 newton m^{-2}; 1 atm $=$ 101,325 Pa. (11.2)

Pauli Exclusion Principle: No two electrons in an atom can have the same values for all four of their quantum numbers. (8.6)

Peptide Bond: The amide linkage in molecules of polypeptides. (23.6)

Percentage Composition: A list of the percentages by weight of the elements in a compound. (4.2)

Percentage Concentration: A ratio of the amount of solute to the amount of solution expressed as a percent. (5.1)
Weight/weight: Grams of solute in 100 g of solution.
Weight/volume: Grams of solute in 100 mL of solution.
Volume/volume: Volumes of solute in 100 volumes of solution.

Percentage Ionization: An equation that quantifies the ionization of a substance in solution. (17.4)

$$\text{Percentage ionization} = \frac{\text{amount of substance ionized}}{\text{initial amount of substance}} \times 100\%$$

Percentage by Mass (Percentage by Weight): (a) The number of grams of an element combined in 100 g of a compound. (4.2) (b) The number of grams of a substance in 100 g of a mixture or solution. (13.5)

Percentage Yield: The ratio (taken as a percent) of the mass of product obtained to the mass calculated from the reaction's stoichiometry. (4.6)

Period: A horizontal row of elements in the periodic table. (3.2)

Periodic Table: A table in which symbols for the elements are displayed in order of increasing atomic number and arranged so that elements with similar properties lie in the same column (group). (Inside front cover, 3.2)

pH: $-\log [H^+]$. (17.1)

Phase: A homogeneous region within a sample. (1.3)

Phase Diagram: A pressure–temperature graph on which are plotted the temperatures and the pressures at which equilibrium exists between the states of a substance. It defines regions of *T* and *P* in which the solid, liquid, and gaseous states of the substance can exist. (12.10)

Photoelectric Effect: The phenomenon whereby energetic photons can eject electrons from certain materials. (8.1)

Photon: A unit of energy in electromagnetic radiation equal to $h\nu$, where ν is the frequency of the radiation and h is Planck's constant. (8.1)

Photosynthesis: The use of solar energy by a plant to make high-energy molecules from carbon dioxide, water, and minerals. (8.1)

Physical Change: A change that is not accompanied by a change in chemical makeup. (1.3)

Physical Law: A relationship between two or more physical properties of a system, usually expressed as a mathematical equation, that describes how a change in one property affects the others.

Physical Property: A property that can be specified without reference to another substance and that can be measured without causing a chemical change. (2.1)

Physical State: The condition of aggregation of a substance's formula units, whether as a solid, a liquid, or a gas. (1.4)

Pi Bond (π Bond): A bond formed by the sideways overlap of a pair of *p* orbitals and that concentrates electron density into two separate regions that lie on opposite sides of a plane that contains an imaginary line joining the nuclei. (10.6)

pK_a: $-\log K_a$. (17.3)

pK_b: $-\log K_b$. (17.3)

pK_w: $-\log K_w$. (17.1)

Planar Triangular Molecule: A molecule in which a central atom holds three other atoms located at the corners of an equilateral triangle and that includes the central atom at its center. (10.1)

Plane-Polarized Light: Light in which all the oscillations occur in one plane. (22.4)

Planck's Constant (*h*): The ratio of the energy of a photon to its frequency; $6.6260755 \times 10^{-34}$ J Hz^{-1}. (8.1)

Plasma: An electrically neutral, very hot gaseous mixture of nuclei and unattached electrons. (21.8)

pOH: $-\log [OH^-]$. (17.1)

Polar Covalent Bond (Polar Bond): A covalent bond in which more than half of the bond's negative charge is concentrated around one of the two atoms. (9.7)

Polar Molecule: A molecule in which individual bond polarities do not cancel and in which, therefore, the centers of density of negative and positive charges do not coincide. (9.7)

Polarizability: A term that describes the ease with which the electron cloud of a molecule or ion is distorted. (12.2)

Polyatomic Ion: An ion composed of two or more atoms. (3.4)

Polydentate Ligand: A ligand that has two or more atoms that can become simultaneously attached to a metal ion. (22.1)

Polymer: A substance consisting of macromolecules that have repeating structural units. (23.5)

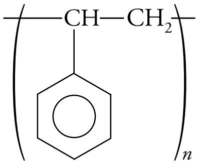
Polymerization: A chemical reaction that converts a monomer into a polymer. (23.5)

Polypeptide: A polymer of α-amino acids that makes up all or most of a protein. (23.6)

Polyprotic Acid: An acid that can furnish more than one H^+ per molecule. (5.3)

Polysaccharide: A carbohydrate whose molecules can be hydrolyzed to hundreds of monosaccharide molecules. (23.6)

Polystyrene: An addition polymer of styrene with the following structure.



polystyrene (23.5)

Position of Equilibrium: The relative amounts of the substances on both sides of the double arrows in the equation for an equilibrium. (5.3, 12.9, 15.5)

Positive Charge: A type of electrical charge possessed by certain particles such as the proton. A positive charge is attracted by a negative charge and is repelled by another positive charge. (3.1)

Positive Charge Carrier: In a semiconductor material doped with an electron deficient element, the holes carry the charge. (20.6)

Positron (${}^{1}_{0}p$): A positively charged particle with the mass of an electron. (21.3)

Post-transition Metal: A metal that occurs in the periodic table immediately to the right of a row of transition elements. (3.4)

Potential: See *Volt.*

Potential Energy (PE): Stored energy. (7.1)

Potential Energy Diagram: A diagram indicating the conversion of kinetic energy to potential energy and back again as atoms or molecules collide and then recoil in a chemical reaction. (13.5)

Precipitate: A solid that separates from a solution usually as the result of a chemical reaction. (5.1)

Precipitation Reaction: A reaction in which a precipitate forms. (5.1, 5.5)

Precision: How reproducible measurements are; the fineness of a measurement as indicated by the number of significant figures reported in the physical quantity. (2.3)

Pre-exponential Factor: A number or variable that precedes the exponential part of a number. (14.7)

Pressure: Force per unit area. (7.5, 11.2)

Pressure–Concentration Law: See *Vapor Pressure–Concentration Law.*

Pressure–Solubility Law (Henry's Law): The concentration of a gas dissolved in a liquid at any given temperature is directly proportional to the partial pressure of the gas above the solution. $C_{\text{gas}} = k_{\text{H}}P_{\text{gas}}$. (13.4)

Pressure–Temperature Law (Gay-Lussac's Law): The pressure of a given mass of gas is directly proportional to its Kelvin temperature if the volume is kept constant. $P \propto T$. (11.3)

Pressure–Volume Law (Boyle's Law): The volume of a given mass of a gas is inversely proportional to its pressure if the temperature is kept constant. $V \propto 1/P$. (11.3)

Pressure–Volume Work (*P–V* Work): The energy transferred as work when a system expands or contracts against the pressure exerted by the surroundings. At constant pressure, $w = -P\,\Delta V$. (7.5)

Primary Cell: A galvanic cell (battery) not designed to be recharged; it is discarded after its energy is depleted. (20.6)

Primitive Cubic Unit Cell: See *Simple Cubic Unit Cell.*

Principal Quantum Number (*n*): The quantum number that defines the principal energy levels and that can have values of 1, 2, 3, . . . , $\propto$. (8.5)

Products: The substances produced by a chemical reaction and whose formulas follow the arrows in chemical equations. (1.6, 15.1)

Propagation Step: A step in a chain reaction for which one product must serve in a succeeding propagation step as a reactant and for which another (final) product accumulates with each repetition of the step. (Chemistry Outside the Classroom 14.1)

Property: A characteristic of matter. (2.1)

Propyl Group: Alkyl group derived from propane, $—CH_2CH_2CH_3$.

Protein: A macromolecular substance found in cells that consists wholly or mostly of one or more polypeptides that often are combined with an organic molecule or a metal ion. (23.6)

Proton (${}^{1}_{1}p$ or ${}^{1}_{1}H^+$): (a) A subatomic particle, with a charge of 1+ and a mass of 1.0072765 u ($1.6726217 \times 10^{-24}$ g) and that is found in atomic nuclei. (3.1) (b) The name often used for the hydrogen ion and symbolized as H^+.

Proton Acceptor: A Brønsted base. (16.1)

Proton Donor: A Brønsted acid. (16.1)

Pure Substance: An element or a compound. (1.3)

Q

Qualitative Analysis: The use of experimental procedures to determine what elements are present in a substance. (5.8)

Qualitative Observation: Observations that do not involve numerical information. (2.2)

Quanta: Packets of electromagnetic radiation now commonly called photons. (8.1)

Quantitative Analysis: The use of experimental procedures to determine the percentage composition of a compound or the percentage of a component of a mixture. (5.8)

Quantitative Observation: An observation involving a measurement and numerical information. (2.2)

Quantized: Descriptive of a discrete, definite amount as of *quantized energy.* (8.3)

Quantum: The energy of one photon. (8.1)

Quantum Mechanics: See *Wave Mechanics.*

Quantum Number: A number related to the energy, shape, or orientation of an orbital, or to the spin of an electron. (8.3)

Quantum Theory: The physics of objects that exhibit wave/particle duality. (8 Introduction)

R

***R*:** See *Gas Constant, Universal.*

Rad (rd): A unit of radiation-absorbed dose and equal to 10^{-5} J g^{-1} or 10^{-2} Gy. (21.6)

Radioactive Decay: The change of a nucleus into another nucleus (or into a more stable form of the same nucleus) by the loss of a small particle or a gamma ray photon. (21.3)

Radioactive Disintegration Series: A sequence of nuclear reactions beginning with a very long-lived radionuclide and ending with a stable isotope of lower atomic number. (21.3)

Radioactivity: The emission of one or more kinds of radiation from an isotope with unstable nuclei. (21.3)

Radiological Dating: A technique for measuring the age of a geologic formation or an ancient artifact by determining the ratio of the concentrations of two isotopes, one radioactive and the other a stable decay product. (13.4, 21.7)

Radionuclide: A radioactive isotope. (21.3)

Raoult's Law: See *Vapor Pressure–Concentration Law*.

Rare Earth Metals: The lanthanides.

Rate: A ratio in which a unit of time appears in the denominator, for example, 40 miles hr^{-1} or 3.0 mol L^{-1} s^{-1}. (14.2)

Rate Constant (*k*): The proportionality constant in the rate law; the rate of reaction when all reactant concentrations are 1 *M*. (14.3)

Rate Law: An equation that relates the rate of a reaction to the molar concentrations of the reactants raised to powers. (14.3)

Rate of Reaction: How quickly the reactants disappear and the products form and usually expressed in units of mol L^{-1} s^{-1}. (14.1, 14.2)

Rate-Determining Step (Rate-Limiting Step): The slowest step in a reaction mechanism. (14.8)

Reactant, Limiting: See *Limiting Reactant*.

Reactants: The substances brought together to react and whose formulas appear before the arrow in a chemical equation. (1.6, 15.1)

Reaction Coordinate: The horizontal axis of a potential energy diagram of a reaction. (14.6)

Reaction Mechanism: A sequence of elementary processes that sum to the overall reaction and possess one process that can derive the experimental rate law. (14.8)

Reaction Quotient (*Q*): The numerical value of the mass action expression. (15.2) See *Mass Action Expression*.

Reactivity: A description of the tendency for a substance to undergo reaction. For a metal, it is the tendency to undergo oxidation. (9.7)

Red Phosphorus: A relatively unreactive allotrope of phosphorus. (10.10)

Redox Reaction: An oxidation–reduction reaction. (6.1)

Reducing Agent: A substance that causes reduction and is itself oxidized. (6.1)

Reduction: A change in which an oxidation number decrease (becomes less positive and more negative). A gain of electrons. (6.1)

Reduction Potential: A measure of the tendency of a given half-reaction to occur as a reduction. (20.2)

Rem: A dose in rads multiplied by a factor that takes into account the variations that different radiations have in their damage-causing abilities in tissue. (20.6)

Replication: In nucleic acid chemistry, the reproductive duplication of DNA double helices prior to cell division. (23.7)

Representative Element: An element in one of the A groups in the periodic table. (3.2)

Resonance: A concept in which the actual structure of a molecule or polyatomic ion is represented as a composite or average of two or more Lewis structures, which are called the resonance or contributing structures (and none of which has real existence). (9.9)

Resonance Energy: The difference in energy between a substance and its principal resonance (contributing) structure. (9.9)

Resonance Hybrid: The actual structure of a molecule or polyatomic ion taken as a composite or average of the resonance or contributing structures. (9.9)

Resonance Structure: A Lewis structure that contributes to the hybrid structure in resonance-stabilized systems; a contributing structure. (9.9)

Reverse Osmosis: The procedure where a pressure, exceeding the osmotic pressure, is applied to an osmotic membrane to force pure solvent from a mixture. (13.7)

Reverse Reaction: In a chemical equation, the reaction as read from right to left. (5.3, 15.1)

Reversible Reaction: A reaction capable of proceeding in either the forward or reverse direction. (13.5, 14.7, 19.7)

Ring, Carbon: A closed-chain sequence of carbon atoms. (23.1)

RNA: Ribonucleic acid; a nucleic acid that gives ribose, phosphate ion, adenine, uracil, guanine, and cytosine when hydrolyzed. It occurs in several varieties. (23.7)

Rock Salt Structure: The face-centered cubic structure observed for sodium chloride, which is also possessed by crystals of many other compounds. (12.11)

Root Mean Square Speed (rms Speed): The square root of the average of the speeds-squared of the molecules in a substance. (11.7)

Rydberg Equation: An equation used to calculate the wavelengths of all the spectral lines of hydrogen. (8.2)

S

Salt: An ionic compound in which the anion is not OH^- or O^{2-} and the cation is not H^+. (5.2, 5.3)

Salt Bridge: A tube that contains an electrolyte that connects the two half-cells of a galvanic cell. (20.1)

Saponification: The reaction of an organic ester with a strong base to give an alcohol and the salt of the organic acid. (23.3)

Saturated Organic Compound: A compound whose molecules have only single bonds. (23.2)

Saturated Solution: A solution that holds as much solute as it can at a given temperature. A solution in which there is an equilibrium between the dissolved and the undissolved states of the solute. (5.1, 18.1)

Scanning Tunneling Microscope (STM): An instrument that enables the imaging of individual atoms on the surface of an electrically conducting specimen. (1.4)

Scientific Law: See *Law*.

Scientific Method: The observation, explanation, and testing of an explanation by additional experiments. (1.2)

Scientific Notation: The representation of a quantity as a decimal number between 1 and 10 multiplied by 10 raised to a power (e.g., 6.02×10^{23}). (2.3)

Scintillation Counter: A device for measuring nuclear radiation that contains a sensor composed of a substance called a *phosphor* that emits a tiny flash of light when struck by a particle of ionizing radiation. These flashes can be magnified electronically and automatically counted. (21.6)

Second Law of Thermodynamics: Whenever a spontaneous event takes place, it is accompanied by an increase in the entropy of the universe. (19.4)

Second-Order Reaction: A reaction with a rate law of the type: rate $= k[A]^2$ or rate $= k[A][B]$, where A and B are reactants. (14.4)

Secondary Cell: A galvanic cell (battery) designed for repeated use; it is able to be recharged. (20.6)

Secondary Quantum Number (ℓ): The quantum number whose values can be 0, 1, 2, …, $(n - 1)$, where n is the principal quantum number. (8.5)

Seesaw Shaped Molecule: A description given to a molecule in which the central atom has five electron pairs in its valence shell, one of which is a lone pair and the others are used in bonds to other atoms. (10.2) See also *Distorted Tetrahedron*.

Selective Precipitation: A technique that uses differences in the solubilities of specific salts to separate ions from each other. (18.3)

Semiconductor: A substance that conducts electricity weakly. (3.3)

Shell: All of the orbitals associated with a given value of n (the principal quantum number). (8.5)

SI (International System of Units): The modified metric system adopted in 1960 by the General Conference on Weights and Measures. (2.2)

Side Reaction: A reaction that occurs simultaneously with another reaction (the main reaction) in the same mixture to produce by-products.

Sievert (Sv): The SI unit for dose equivalent. The dose equivalent H is calculated from D (the dose in grays), Q (a measure of the effectiveness of the radiation at causing harm), and N (a variable that accounts for other modifying factors). $H = DQN$. (21.6)

Sigma Bond (σ Bond): A bond formed by the head-to-head overlap of two atomic orbitals and in which electron density becomes concentrated along and around the imaginary line joining the two nuclei. (10.6)

Significant Figures (Significant Digits): The digits in a physical measurement that are known to be certain plus the first digit that contains uncertainty. (2.3)

Simple Cubic Unit Cell: A cubic unit cell that has atoms only at the corners of the cell. (12.11)

Simplest Formula: See *Empirical Formula.*

Single Bond: A covalent bond in which a single pair of electrons is shared. (9.5)

Single Replacement Reaction: A reaction in which one element replaces another in a compound; usually a redox reaction. (6.4)

Skeletal Structure: A diagram of the arrangement of atoms in a molecule, which is the first step in constructing the Lewis structure. (9.8)

Skeleton Equation: An unbalanced equation showing only the formulas of reactants and products. (6.2)

Solar Battery: A battery that is charged by electrical current from photovoltaic cells. (10.9)

Solar Cell: A semiconductor device that produces electrical current and voltage in the presence of sunlight. (10.9)

Sol-Gel Process: A method for producing sol gels, very porous materials. (16.6)

Solid: One of the states of matter. A solid consists of tightly packed atomic or molecular sized particles held rigidly in place. (2.1)

Solubility: The ratio of the quantity of solute to the quantity of solvent in a saturated solution and that is usually expressed in units of (g solute)/(100 g solvent) at a specified temperature. (5.1)

Solubility Product Constant (K_{sp}): The equilibrium constant for the solubility of a salt and that, for a saturated solution, is equal to the product of the molar concentrations of the ions, each raised to a power equal to the number of its ions in one formula unit of the salt. (18.1) See also *Acid Solubility Product.*

Solubility Rules: A set of rules describing salts that are soluble and those that are insoluble. They enable the prediction of the formation of a precipitate in a metathesis reaction. (5.5)

Solute: Something dissolved in a solvent to make a solution. (5.1)

Solution: A homogeneous mixture in which all particles are of the size of atoms, small molecules, or small ions. (1.3, 5.1)

Solvation: The development of a cagelike network of a solution's solvent molecules about a molecule or ion of the solute. (13.1)

Solvation Energy: The enthalpy of the interaction of gaseous molecules or ions of solute with solvent molecules during the formation of a solution. (13.2)

Solvent: A medium, usually a liquid, into which something (a solute) is dissolved to make a solution. (5.1)

Space Filling Model: A method of depicting molecules by the shape and volume that the molecule actually occupies. (1.5)

***sp* Hybrid Orbital:** A hybrid orbital formed by mixing one *s* and one *p* atomic orbital. The angle between a pair of *sp* hybrid orbitals is 180°. (10.5)

sp^2 Hybrid Orbital: A hybrid orbital formed by mixing one *s* and two *p* atomic orbitals. sp^2 hybrids are planar triangular with the angle between two sp^2 hybrid orbitals being 120°. (10.5)

sp^3 Hybrid Orbital: A hybrid orbital formed by mixing one *s* and three *p* atomic orbitals. sp^3 hybrids point to the corners of a tetrahedron; the angle between two sp^3 hybrid orbitals is 109.5°. (10.5)

sp^3d Hybrid Orbital: A hybrid orbital formed by mixing one *s*, three *p*, and one *d* atomic orbital. sp^3d hybrids point to the corners of a trigonal bipyramid. (10.5)

sp^3d^2 Hybrid Orbital: A hybrid orbital formed by mixing one *s*, three *p*, and two *d* atomic orbitals. sp^3d^2 hybrids point to the corners of an octahedron. (10.5)

Specific Gravity: A dimensionless property of matter. Its value is determined by dividing the density by the density of water under the same conditions. (2.5)

Specific Heat (Specific Heat Capacity): The quantity of heat that will raise the temperature of 1 g of a substance by 1 °C, usually in units of cal g^{-1} °C^{-1} or J g^{-1} °C^{-1}. (7.3)

Spectator Ion: An ion whose formula appears in an ionic equation identically on both sides of the arrow, that does not participate in the reaction, and that is excluded from the net ionic equation. (5.2)

Spectrochemical Series: A listing of ligands in order of their ability to produce a large crystal field splitting. (22.5)

Speed of Light (c): The speed at which light travels in a vacuum; 3.00×108 m s^{-1}. (7.1)

Spin Quantum Number (m_s): The quantum number associated with the spin of a subatomic particle and for the electron can have a value of $+\frac{1}{2}$ or $-\frac{1}{2}$. (8.6)

Spontaneous Change: A change that occurs by itself without outside assistance. (19.2)

Square Planar Molecule: A molecule with a central atom having four bonds that point to the corners of a square. (10.2)

Square Pyramid: A pyramid with four triangular sides and a square base. (10.2)

Stability Constant: See *Formation Constant.*

Stabilization Energy: See *Resonance Energy.*

Standard Atmosphere: See *Atmosphere, Standard*

Standard Cell Notation: A way of describing the anode and cathode half-cells in a galvanic cell. The anode half-cell is specified on the left, with the electrode material of the anode given first and a vertical bar representing the phase boundary between the electrode and the solution. Double bars represent the salt bridge between the half-cells. The cathode halfcell is specified on the right, with the material of the cathode given last. Once again, a single vertical bar represents the phase boundary between the solution and the electrode. (20.1)

Standard Cell Potential (E°_{cell}): The potential of a galvanic cell at 25 °C and when all ionic concentrations are exactly 1 *M* and the partial pressures of all gases are 1 atm. (20.2)

Standard Conditions of Temperature and Pressure (STP): Standard reference conditions for gases. 273 K (0 °C) and 1 atm (760 torr). (11.4)

Standard Electrode Potential: The electrode potential measured versus the standard hydrogen electrode at standard state conditions. (20.2)

Standard Enthalpy Change (ΔH°): See *Standard Heat of Reaction.*

Standard Enthalpy of Formation (ΔH°_f): See *Standard Heat of Formation.*

Standard Entropy (S°): The entropy of 1 mol of a substance at 25 °C and 1 atm. (19.5)

Standard Entropy Change (ΔS°): The entropy change of a reaction when determined with reactants and products at 25 °C and 1 atm and on the scale of the mole quantities given by the coefficients of the balanced equation. (19.5)

Standard Entropy of Formation (ΔS_f°): The value of ΔS° for the formation of one mole of a substance from its elements in their standard states. (19.5)

Standard Free Energy Change (ΔG°): $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$. (19.6)

Standard Free Energy of Formation (ΔG_f°): The value of ΔG° for the formation of *one* mole of a compound from its elements in their standard states. (19.6)

Standard Heat of Combustion: The enthalpy change for the combustion of one mole of a compound under standard conditions. (7.9)

Standard Heat of Formation (ΔH_f°): The amount of heat absorbed or evolved when one mole of the compound is formed from its elements in their standard states. (7.9)

Standard Heat of Reaction (ΔH°): The enthalpy change of a reaction when determined with reactants and products at 25 °C and 1 atm and on the scale of the mole quantities given by the coefficients of the balanced equation. (7.7)

Standard Hydrogen Electrode: See *Hydrogen Electrode*.

Standard Molar Volume: See *Molar Volume, Standard*.

Standard Reduction Potential, E°: The reduction potential of a half-reaction at 25 °C when all ion concentrations are 1 *M* and the partial pressures of all gases are 1 atm. Also called standard electrode potential. (20.2)

Standard Solution: Any solution whose concentration is accurately known. (5.8)

Standard State: The condition in which a substance is in its most stable form at 25 °C and 1 atm. (7.7, 7.9, 20.2)

Standing Wave: A wave whose peaks and nodes do not change position. (8.4)

Starch: A polymer of glucose used by plants to store energy. (23.6)

State: The set of specific values of the physical properties of a system—its composition, physical form, concentration, temperature, pressure, and volume. (7.2)

State Function: A quantity whose value depends only on the initial and final states of the system and not on the path taken by the system to get from the initial to the final state. (*P, V, T, H, S*, and *G* are all state functions.) (7.2)

State of Matter: A physical state of a substance: solid, liquid, or gas. (2.1) See also *Standard State*.

Steady State: A system where material or energy enter and exit at the same rate producing no observable changes in pressure, volume, temperature or amount of material. (11.9)

Step-Growth Polymer: See *Condensation Polymer*

Stereoisomerism: The existence of isomers whose structures differ only in spatial orientations (e.g., geometric isomers and optical isomers). (22.4)

Stock System: A system of nomenclature that uses Roman numerals to specify oxidation states. (3.5)

Stoichiometry: A description of the relative quantities by moles of the reactants and products in a reaction as given by the coefficients in the balanced equation. (4.1)

Stopcock: A valve on a buret that is used to control the flow of titrant. (5.8)

Stored Energy: See *Potential Energy*.

STP: See *Standard Conditions of Temperature and Pressure*.

Straight-Chain Compound: An organic compound in whose molecules the carbon atoms are joined in one continuous open-chain sequence. (23.1)

Strong Acid: An acid that is essentially 100% ionized in water. A good proton donor. An acid with a large value of K_a. (5.3)

Strong Base: Any powerful proton acceptor. A base with a large value of K_b. A metal hydroxide that dissociates essentially 100% in water. (5.3)

Strong Electrolyte: Any substance that ionizes or dissociates in water to essentially 100%. (5.2, 5.3)

Structural Formula (Lewis Structure): A chemical formula that shows how the atoms of a molecule or polyatomic ion are arranged, to which other atoms they are bonded, and the kinds of bonds (single, double, or triple). (9.5)

Subatomic Particles: Electrons, protons, neutrons, and atomic nuclei. (3.1)

Sublimation: The conversion of a solid directly into a gas without passing through the liquid state. (12.3)

Subscript: In a chemical formula, a number after a chemical symbol, written below the line, and indicating the number of the preceding atoms in the formula (e.g., CH_4). Subscripts are also used to differentiate many variables such as the acid ionization constant (K_a) and the base ionization constant (K_b). (1.5)

Subshell: All of the orbitals of a given shell that have the same value of their secondary quantum number, ℓ. (8.5)

Substance: See *Pure Substance*.

Substitution Reaction: The replacement of an atom or group on a molecule by another atom or group. (23.2, 23.3)

Superconductor: A material in a state in which it offers no resistance to the flow of electricity.

Supercooled Liquid: A liquid at a temperature below its freezing point. An amorphous solid. (12.11)

Supercritical Fluid: A substance at a temperature above its critical temperature. (12.10)

Superheated Liquid: The condition of a substance in its liquid state above its boiling point. (12.7)

Superheating: The process where a substance is heated to a temperature above its normal boiling point. (12.7)

Superimposability: A test of structural chirality in which a model of one structure and a model of its mirror image are compared to see if the two could be made to blend perfectly, with every part of one coinciding simultaneously with the parts of the other. (22.4)

Supersaturated Solution: A solution that contains more solute than it would hold if the solution were saturated. Supersaturated solutions are unstable and tend to produce precipitates. (5.1)

Surface Tension: A measure of the amount of energy needed to expand the surface area of a liquid. (12.3)

Surfactant: A substance that lowers the surface tension of a liquid and promotes wetting. (12.3)

Surroundings: That part of the universe other than the system being studied and separated from the system by a real or an imaginary boundary. (7.3)

Suspension: A heterogeneous mixture that will eventually separate into its component parts under the influence of gravity. (13.8)

Symmetric: An object is symmetric if it looks the same when rotated, reflected in a mirror, or reflected through a point. (10.3)

System: That part of the universe under study and separated from the surroundings by a real or an imaginary boundary. (7.3, 7.7)

T

$t_{1/2}$: See *Half-Life*.

T-Shaped Molecule: A molecule having five electron domains in its valence shell, two of which contain lone pairs. The other three are used in bonds to other atoms. The molecule has the shape of the letter T, with the central atom located at the intersection of the two crossing lines. (10.2)

Tarnishing: See *Corrosion*.

Temperature: A measure of the hotness or coldness of something. A property related to the average kinetic energy of the atoms and molecules in a sample. A property that determines the direction of heat flow—from high temperature to low temperature. (2.2, 7.1)

Temperature–Volume Law (Charles' Law): The volume of a given mass of a gas is directly proportional to its Kelvin temperature if the pressure is kept constant. $V \propto T$. (11.3)

Termination Step: A step in a chain reaction in which a reactive species needed for a chain propagation step disappears without helping to generate more of this species. (Chemistry Outside the Classroom 14.1)

Tetrahedral Molecule: A molecule with a central atom bonded to four other atoms located at the corners of an imaginary tetrahedron. (10.1)

Tetrahedron: A four-sided figure with four triangular faces and shaped like a pyramid. (10.1)

Theoretical Model: See *Model, Theoretical.*

Theoretical Yield: See *Yield, Theoretical*

Theory: A tested explanation of the results of many experiments. (1.2)

Thermal Decomposition: The decomposition of a substance caused by heating it. (21.3)

Thermal Energy: The molecular kinetic energy possessed by molecules as a result of the temperature of the sample. Energy that is transferred as heat. (7.1)

Thermal Equilibrium: A condition reached when two or more substances in contact with each other come to the same temperature. (7.2)

Thermal Property: A physical property, like heat capacity or heat of fusion, that concerns a substance's ability to absorb heat without changing chemically.

Thermochemical Equation: A balanced chemical equation accompanied by the value of $\Delta H°$ that corresponds to the mole quantities specified by the coefficients. (7.7)

Thermochemistry: The study of the energy changes of chemical reactions. (7 Introduction)

Thermodynamic Equilibrium Constant (*K*): The equilibrium constant that is calculated from $\Delta G°$ (the standard free energy change) for a reaction at T K by the equation, $\Delta G° = RT \ln K$. (19.9)

Thermodynamically Reversible: A process that occurs by an infinite number of steps during which the driving force for the change is just barely greater than the force that resists the change. (19.7)

Thermodynamics (Chemical Thermodynamics): The study of the role of energy in chemical change and in determining the behavior of materials. (7 Introduction, 19.1)

Third Law of Thermodynamics: For a pure crystalline substance at 0 K, $S = 0$. (19.5)

Titrant: The solution added from a buret during a titration. (5.8)

Titration: An analytical procedure in which a solution of unknown concentration is combined slowly and carefully with a standard solution until a color change of some indicator or some other signal shows that equivalent quantities have reacted. Either solution can be the titrant in a buret with the other solution being in a receiving flask. (5.8)

Titration Curve: For an acid–base titration, a graph of pH versus the volume of titrant added. (17.9)

Torr: A unit of pressure equal to 1/760 atm. 1 mm Hg. (11.2)

Tracer Analysis: The use of small amounts of a radioisotope to follow (trace) the course of a chemical or biological change. (21.7)

Trans Isomer: A stereoisomer whose uniqueness lies in having two groups that project on opposite sides of a reference plane. (22.4)

Transcription: The synthesis of mRNA at the direction of DNA. (23.7)

Transition Elements: The elements located between Groups 2A and 3A in the periodic table. (3.2)

Transition Metals: The transition elements. (3.2)

Transition State: The structure and energy of the substances in an elementary process of a reaction mechanism when the species involved have acquired the minimum amount of potential energy and geometric configuration needed for a successful reaction. (14.6)

Transition State Theory: A theory about the formation and breakup of activated complexes. (14.6)

Translation: The synthesis of a polypeptide at the direction of a molecule of mRNA. (23.7)

Transmutation: The conversion of one isotope into another. (21.5)

Transuranium Elements: Elements 93 and higher. (21.5)

Traveling Wave: A wave whose peaks and nodes move. (8.4)

Triacylglycerol: An ester of glycerol and three fatty acids. (23.6)

Trigonal Bipyramid: A six-sided figure made of two three-sided pyramids that share a common face. (10.1)

Trigonal Bipyramidal Molecule: A molecule with a central atom holding five other atoms that are located at the corners of a trigonal bipyramid. (10.1, 10.2)

Trigonal Pyramidal Molecule: A molecule that consists of an atom, situated at the top of a three-sided pyramid, that is bonded to three other atoms located at the corners of the base of the pyramid. (10.2)

Triple Bond: A covalent bond comprised of one sigma bond and two pi bonds. Three pairs of electrons are shared between two atoms. (10.6)

Triple Point: The temperature and pressure at which the liquid, solid, and vapor states of a substance can coexist in equilibrium. (12.10)

Triprotic Acid: An acid that can furnish three H^+ ions per molecule. (5.3)

Tyndall Effect: Colloidal dispersions scatter light while true solutions do not scatter light. This light scattering is known as the Tyndall effect. (13.8)

U

u: See *Atomic Mass Unit.*

Ultraviolet Catastrophe: The term given to the fact that classical physics predicts large amounts of ultraviolet radiation should be emitted from heated materials. In fact, very little ultraviolet radiation is produced. (7 Introduction)

Uncertainty: The amount by which a measured quantity deviates from the true or actual value. (2.3)

Uncertainty Principle: There is a limit to our ability to measure a particle's speed and position simultaneously. (8.9)

Unit Cell: The smallest portion of a crystal that can be repeated over and over in all directions to give the crystal lattice. (12.11)

Unit of Measurement: A reference quantity, such as the meter or kilogram, in terms of which the sizes of measurements can be expressed. (2.2)

Universal Gas Constant (*R*): See *Gas Constant, Universal.*

Universe: The system and surroundings taken together. (7.3)

Unsaturated Compound: A compound whose molecules have one or more double or triple bonds. (23.2)

Unsaturated Solution: Any solution with a concentration less than that of a saturated solution of the same solute and solvent. (5.1)

V

V-Shaped Molecule: See *Bent Molecule.*

Vacuum: An enclosed space containing no matter whatsoever. A *partial vacuum* is an enclosed space containing a gas at a very low pressure.

Valence Band: Very closely spaced energy levels of valence electrons, particularly in metals is called the valence band. (10.9)

Valence Bond Theory (VB Theory): A theory of covalent bonding that views a bond as being formed by the sharing of one pair of electrons between two overlapping atomic or hybrid orbitals. (10.4)

Valence Electrons: The electrons of an atom in its valence shell that participate in the formation of chemical bonds. (8.8)

Valence Shell: The electron shell with the highest principal quantum number, *n*, that is occupied by electrons. (8.8)

Valence Shell Electron Pair Repulsion Model (VSEPR Model): The bonding and nonbonding (lone pair) electron domains in the valence shell of an atom seek an arrangement that leads to minimum repulsions and thereby determine the geometry of a molecule. (10.2)

Van der Waals' Constants: Empirical constants that make the van der Waals' equation conform to the gas law behavior of a real gas. (11.8)

Van der Waals' Equation: An equation of state for a real gas that corrects V and P for the excluded volume and the effects of intermolecular attractions. (11.8)

Van der Waals' Forces: Attractive forces including dipole–dipole, ion–dipole, and induced dipole forces. (12.2)

Van't Hoff Factor (i): The ratio of the observed freezing point depression to the value calculated on the assumption that the solute dissolves as un-ionized molecules. (13.7)

Vapor Pressure: The pressure exerted by the vapor above a liquid (usually referring to the *equilibrium* vapor pressure when the vapor and liquid are in equilibrium with each other). (11.6, 12.5)

Vapor Pressure–Concentration Law (Raoult's Law): The vapor pressure of one component above a mixture of molecular compounds equals the product of its vapor pressure when pure and its mole fraction. (13.7)

Viscosity: A liquid's resistance to flow. (12.3)

Visible Spectrum: That region of the electromagnetic spectrum whose frequencies can be detected by the human eye. (8.1)

Volatile: Descriptive of a liquid that has a low boiling point, a high vapor pressure at room temperature, and therefore evaporates easily. (12.5, 13.7)

Volt (V): The SI unit of electric potential or emf in joules per coulomb. (20.2)

$$1\ \text{V} = 1\ \text{J C}^{-1}$$

Voltaic Cell: See *Galvanic Cell.*

Volumetric Flask: A piece of glassware calibrated to hold an exact volume of liquid. Volumetric flasks come in a variety of sizes. (5.6)

VSEPR Model: See *Valence Shell Electron Pair Repulsion Model.*

W

Wave: An oscillation that moves outward from a disturbance. (8.1)

Wave Function (ψ): A mathematical function that describes the intensity of an electron wave at a specified location in an atom. The square of the wave function at a particular location specifies the probability of finding an electron there. (8.4)

Wave Mechanics (Quantum Mechanics): A theory of atomic structure based on the wave properties of matter. (8 Introduction)

Wave/Particle Duality: A particle such as the electron behaves like a particle in some experiments and like a wave in others. (8 Introduction)

Wavelength (λ): The distance between crests in the wavelike oscillations of electromagnetic radiations. (8.1)

Weak Acid: An acid with a low percentage ionization in solution; a poor proton donor; an acid with a low value of K_a. (5.3)

Weak Base: A base with a low percentage ionization in solution; a poor proton acceptor; a base with a low value of K_b. (5.3)

Weak Electrolyte: A substance that has a low percentage ionization or dissociation in solution. (5.3)

Weighing: The operation of measuring the mass of something using a balance. (1.5)

Weight: The force with which something is attracted to the earth by gravity. (1.3)

Weight Percent: See *Percentage by Mass.*

Wetting: The spreading of a liquid across a solid surface. (12.3)

White Phosphorus: A very reactive allotrope of phosphorus consisting of tetrahedral P_4 molecules. (10.10)

Work (w): The energy expended in moving an opposing force through some particular distance. Work has units of *force* × *distance*. (6.1, 6.5, 18.1)

X

X Ray: A stream of very high-energy photons emitted by substances when they are bombarded by high-energy beams of electrons or are emitted by radionuclides that have undergone K-electron capture. (21.3)

Xerogel: An extremely low density material that, among other things, can serve as a very low weight insulating material. (16.6)

Y

Yield, Actual: The amount of a product obtained in a laboratory experiment. (4.6)

Yield, Percentage: The ratio, given as a percent, of the quantity of product actually obtained in a reaction to the theoretical yield. (4.6)

Yield, Theoretical: The amount of a product calculated by the stoichiometry of the reaction. (4.6)

Z

Zero-Order Reaction: A reaction that occurs at a constant rate regardless of the concentration of the reactant. (14.4)

Zinc–Manganese Dioxide Cell (Leclanché Cell): A galvanic cell of about 1.5 V involving zinc and manganese dioxide under mildly acidic conditions. (20.6)

  thermal cushion of, 262
Hund's rule, 329–330, 450
Hybrid atomic orbitals, 427–445
  and coordinate covalent bonds, 438–439
  defined, 427
  and double bonds, 439–445
  and molecular geometries, 427–439
  and nonbonding domains, 436–438
  sigma bonds and molecular structure, 443–445
  sp, 428–432
  sp^3d and sp^3d^2 orbitals, 434–436
  and triple bonds, 439–445
  and valence bond theory, 429
  VSEPR model for, 429, 432–434
Hydrates, 13, 89, 158, 1020–1021
Hydrated aluminum ions, 760–761
Hydrated oxides, 929
Hydration, of ions, 588–589
Hydration energy, 589, 590
Hydraulics, 537
Hydrazine, 208
Hydrides, nonmetal, 91–92
Hydride ions, 948
hydro- (prefix), 173
Hydrocarbons, 92–93
  alkanes, 1053–1057
  alkenes and alkynes, 1057–1059
  and alkyl groups, 1055–1056
  aromatic, 1053, 1060
  boiling points of, 531
  cracking of, 677, 682, 1057
  as fuels, 235–236

- Hydrochloric acid:
  - and ammonia, 741–742, 815–816
  - and limestone, 180
  - and milk of magnesia, 178, 179
  - and sodium bicarbonate, 180
  - and sodium hydroxide, 178, 811–813
  - strength of, 748
  - and water, 742
  - and zinc metal, 128–129, 227–228
- Hydroelectric power plants, 946
- Hydrogen:
  - in activity series, 232–233
  - and alkenes, 1059
  - atomic mass of, 70
  - in balanced redox reactions, 223
  - in binary compounds, 173, 547–548
  - Bohr model of, 317–318
  - covalent bonding of, 368–369
  - electron configuration of, 328
  - line spectrum of, 315–316
  - in molecular compounds, 91–92
  - molecular orbitals of, 447
  - valence electrons of, 385
  - in VB theory, 425
  - from water, 726
- Hydrogenation, 1059, 1064, 1081
- Hydrogen bonds:
  - and boiling point, 548
  - in DNA, 1086
  - and heat of vaporization, 552
  - as intermolecular forces, 532–534
- Hydrogen chloride, 487n.7, 1059
- Hydrogen electrode, standard, 926–928
- Hydrogen fluoride:
  - atomic mass of, 70
  - bonding in, 450–451
  - in VB theory, 425–426
- Hydrogen iodide, 641, 698–699
- Hydrogen ions, *see* Hydronium ions
- Hydrogen–oxygen fuel cells, 950

- Oxalates, 832
- Oxalate ions, 1018
- Oxidation:
  - of alcohols, 1061–1062, 1066–1067
  - of aldehydes and ketones, 1065
  - defined, 214
  - in galvanic half-cells, 925
  - identifying, 220
  - and reactivity, 381
- Oxidation numbers:
  - and acidity of metal oxides, 761–762
  - assigning, 217–220
  - identifying reduction and oxidation with, 220–221
  - and redox changes, 216–217
- Oxidation–reduction (redox) reactions, 213–242
  - acids in, 227–230
  - balancing, 222–227
  - and cell reactions, 921
  - defined, 216
  - described, 214–216
  - of metals, 231–235
  - in multi-concept problems, 240–242
  - oxidation numbers in, 216–221
  - oxygen in, 235–239
  - separation of, 919
  - stoichiometry of, 239–240
- Oxidation state:
  - in crystal field theory, 1033
  - defined, 216

  of metal complexes, 1024–1025, 1034
Oxides:
  acid–base chemistry for, 761–762
  hydrated, 929
  ionic, 167–168, 235
  metal, 845–846
Oxide ions, 347–348, 748–749, 757
Oxidizing agents:
  acids, 227–230
  defined, 214, 215
  nonmetals, 382
  oxygen, 235–239
  reduction potentials of, 928
Oxoacids:
  Lewis structures of, 383–384
  nomenclature for, 173–174
  strength of, 751–755
Oxoanions, 754
Oxygen:
  bonding in, 456
  and carbon, 374–376
  electronic structure of, 450
  and glucose, 132–133
  hybrid orbitals of, 436–437
  ionization energy of, 349
  lone oxygens, 753
  in organic compounds, 1060–1067
  oxoacid strength and binding of, 753
  as real gas, 513
  in redox reactions, 223, 235–239
  in stratosphere, 645
Ozone:
  bonds in, 456–457
  and ozone layer, 353, 516
  and Smoky Mountains, 245
  in water treatment, 246
Ozone hole, 516
Ozone layer, 353, 370, 516

P

P_c (critical pressure), 558, 560
PABA (*para*-Aminobenzoic acid), 825
Packing, in solids/liquids, 537, 566–568
Paired electrons, 328
Pairing energy, 1036
Paramagnetism, 328
Parent chains (parent rings):
  of alcohols, 1061
  of aldehydes and ketones, 1064
  of alkanes, 1053, 1054
  of alkenes and alkynes, 1058
Partial negative charge, 377, 399
Partial positive charge, 377, 399
Partial pressure. *See also* Dalton's law of partial pressures
  of gases, 499
  in mass action expression, 704–706
  and Raoult's law for volatile solvents, 606–607
Particle accelerators, 991–992
Parts per billion (unit), 598
Parts per hundred (unit), 598
Parts per million (unit), 598
Pascal (unit), 476
Pauli, Wolfgang, 327, 983

Pentane, 630
Pentanoic acid, 208
Peptide bonds, 1083–1084
per- (prefix), 173
Percentage by mass, 116, 597–598
Percentage composition, 116–118, 122–123
Percentage concentration (percent concentration), 156, 597–598
Percentage ionization, 784, 786, 791–792
Percentage yield, 139–141
Percent by mass/volume, 598n.5, 602
Percent by weight, 597. *See also* Percentage by mass
Perchloric acid ($HClO_4$), 754
Perclene, 496
Periods (periodic table), 74
  atomic size and multiple bonds in, 456–460
  electron affinity of, 349
  and ground state electron configurations, 331–332
  ionization energy of, 345–346
Period 2 elements, bonds of, 456–458
Periodic table, 72–78
  and atomic mass, 69
  development of, 72–75
  and elements' properties, 340–349
  and ground state electron configurations, 330–337
  metals, nonmetals, and metalloids in, 75–78
Periodic trends:
  in acidity of metal ions, 760–761
  in acid strength, 750–755
  in atomic/ionic size, 340–343
  in crystal field theory, 1033
  in effective nuclear charge, 340
  in electron affinity, 347–348
  in electronegativity, 381
  in ionization energy, 343–347
  irregularities in, 348–349
Permeability, of membranes, 612
Pertechnetate ion, 999
PET (positron emission tomography), 990
pH:
  acid–base indicators for measuring, 818–819
  of buffer solutions, 799–805
  and hydronium ions, 776–778
  and hydroxide ions, 778–779
  from initial concentrations, 790–791
  and ionization constants, 785–786
  measurements of, 818–819
  and percentage ionization, 791–792
  of salt solutions, 793–797, 810
  of strong acids and bases, 778–779
  and temperature, 776
  and water, 775–778
  of weak acids and bases, 788–793
Phases, of heterogeneous mixtures, 7, 638
Phase boundaries, in standard cell notation, 923
Phase diagrams, 556–560, 608
Phenophthalein, 198
Phenyl group, 623
pH meters, 778, 818, 943
Phosgene, 913
Phosphors, 994
Phosphoric acid, 166, 208
Phosphorus, 459–460
Photoelectric effect, 312, 313, 344
Photoelectron spectroscopy, 344–345
Photons, 311–313, 985
Photosynthesis, 266
Photovoltaic cells, 951–952
Physical changes, 8
Physical properties, 30–31
  of atmosphere, 515–516
  of gases, 473–474
  measurements of, 32–41
  of organic polymers, 1076–1077
  of solids, 571–574
Physical states of matter, *see* States of matter
Pi bonds (π bonds), 439–444, 456
pico- (prefix), 35
Piezoelectric ceramics, 763
pK_a, 781, 783
pK_b, 782, 783
pK_w, 777
Planar triangular molecules, 410, 412
Planck, Max, 312
Planck's constant, 312, 319, 344
Plane-polarized light, 1031
Plasma, 1004
Plaster, 13
p-n junctions, 455
"p" notation, 777
pOH, 777
Poisoning, of catalysts, 683
Polar bonds (polar covalent bonds), 377–379
Polarity:
  and acidity, 752, 760
  and bond dipoles, 421–424
  and electronegativity, 377–379
  in galvanic cells, 922
  and heat of vaporization, 552
  and molecular structure, 423–424
  negative and positive, 922
  and solubility, 587–589
Polarizability, of electron cloud, 530
Polarized light, 1030–1031
Polar molecules, 378, 532
Pollution, 40, 151
Polyatomic ions, 84–85, 88–89
Polydentate ligands, 1018, 1021–1022
Polyester, 1075–1076
Polyethylene, 1072, 1076
Polygons, carbon rings as, 1050–1051
Polymers, 632, 1070–1077
Polymer crystallinity, 1076–1077
Polymerization, 1071
Polypeptides, 1083–1084, 1087–1088
Polypropylene, 1071
Polyprotic acids, 166, 805–810
Polysaccharides, 1079
Polystyrene, 1072–1073
Polyunsaturated fats, 1080
p orbitals, 329–330
  hybrid orbitals with, 428–438
  in molecular orbitals, 448
  and pi bonds, 439–440
  shapes and orientations of, 338–339

Porphyrin structure, 1039
Portland cement, 133, 498
Position of equilibrium:
  and catalysts, 714
  and equilibrium constant, 708–709
  and Le Châtelier's principle, 555–556
  and reciprocal acid–base relationships, 749–750
  and standard free energy change, 896–898
  for weak acids, 172
Positive catalysts, 680
Positive charge, 68, 760
Positive charge carriers, 951
Positive charge density, 760
Positive ions, 66, 572
Positive polarity, 922
Positrons, 985
Positron emission, 985–986
Positron emission tomography (PET), 990
Positron emitters, 990
Post-transition metals:
  cations of, 83–84, 363–364
  complex ions of, 855
Potassium-40, 997–1000
Potassium iodate, 251
Potassium iodide:
  heat of solution for, 589–590
  and lead(II) nitrate, 160–162, 175–176
Potassium permanganate, 239–240
Potassium sulfate, 954–956
Potential, of galvanic cells, 924
Potential energy (PE), 254–256
  of covalent bond formation, 369
  and electron affinity, 347
  of electrons in atoms, 316–317
  on heating and cooling curves, 549
  of ions, 361–362
  and surface tension, 538
  and transition state theory, 667–669
Power:
  of microscope, 320
  nuclear, 1002
  wind, 946
Power plants, 946, 1002–1003
Precipitates, 157, 160, 841–843
Precipitation reactions:
  defined, 157
  and hard water, 181
  for metal carbonates, 851n.3
  as metathesis reactions, 175–177
  selective, 847–855
  for silver bromide, 191
Precision, 43, 55
Pre-exponential factor, 670
Pressure:
  atmospheric, 267, 474, 546, 547
  barometers, 474–475
  in calorimetry, 267–269, 272–275
  and chemical equilibrium, 703–706, 712, 714
  critical, 558, 560
  external, 871
  and heat of reaction, 272, 872
  heat of reaction at constant pressure, 272–275, 872
  manometers, 477–480
  measuring, 474–480
  and melting point, 556–557
  osmotic, 613–618
  partial, *see* Partial pressure
  SI units of, 476, 884n.2
  standard temperature and, 487, 494–495, 884n.2
  vapor, *see* Vapor pressure
Pressure cookers, 673
Pressure sensors, 480
Pressure–temperature law (Gay-Lussac's law), 482, 511
Pressure–volume law (Boyle's law), 480–481, 510–511
Pressure–volume work, 268–269, 871–872
Pressurized water reactors, 1002–1003
Primary cells, 946
Primitive (simple) cubic lattice, 561–562
Principal quantum number (n), 324
Problem solving, tips on, 14
Products:
  of acid and base ionization constants, 783–784
  defined, 20
  of electrolysis reactions, 956–958
  in equilibrium, 697–698, 710–711
  ion, 832–833, 841–843
  by products, 139
Propagation step, of chain reactions, 677
Propanal, 1064
Propane, 297, 640, 641
Properties (term), 30
Propionic acid, 790
Propylene, 1058
Propylene glycol, 536
Propyl group, 1055
Proteins, 533, 1083–1085
Protons, 65–67
  in band of stability, 989
  and Brønsted–Lowry acids and bases, 741
  of isotopes, 69
  repulsions between, 980
  size and charge of, 68
Protonated amines, 1068
Proton–proton cycle, 1005
Proton transfer reactions, 742
p subshells, 339
p-type semiconductors, 454, 951
Pure substances, 7
Pycnometer, 61
Pyridine, 208
Pyrimidine bases, 370

Q

Q, *see* Reaction quotient
q_p (heat of reaction at constant pressure), 272–275, 872
q_v (heat of reaction at constant volume), 270–271
Qualitative analysis:
  of aqueous solutions, 196
  of metal ions, 854–855
Qualitative observations, 32
Quanta, 312
Quantitative analysis, for aqueous solutions, 196–197
Quantitative observations, 32
Quantitative reactions, 597
Quantized energies, 316–317, 321–324
Quantum mechanics, 305–350
  atomic orbitals, 337–340
  Bohr theory, 316–318
  defined, 306
  electromagnetic radiation, 306–313
  electron spin, 326–328
  and elements' properties, 340–349
  energy levels, 328–330
  ground state electron configurations, 328–337
  line spectra and Rydberg equation, 314–316
  periodic table, 330–337, 340–349
  and quantum numbers of electrons, 324–325
  wave mechanical model, 318–324
Quantum numbers:
  defined, 317
  of electrons, 324–325
  magnetic, 325
  and Pauli exclusion principle, 327–328
  principal, 324
  secondary, 324–325
  spin, 327
  and standing waves, 321–323
Quantum theory, 306
Quinine, 1068

R

R (universal gas constant), 490, 552
R (symbol), in structural formulas, 1052–1053
Rad (radiation absorbed dose), 996
Radiation, 98, 404
  alpha, 981–982
  annihilation radiation photons, 985
  atomic, 980
  background, 997–998

  electromagnetic, *see* Electromagnetic radiation
  energy from, 983–984
  gamma, 983–984, 999
  and greenhouse effect, 517, 518
  ionizing, 994, 997
  and living tissue, 997–998
  nuclear, 980
  units of, 994–997
Radiation absorbed dose (rad), 996
Radiation sickness, 997
Radicals, free, 677, 997, 1072
Radioactive decay:
  and alpha rays, 66
  and carbon-14 dating, 659–660
  defined, 981
  law of, 995–996
  modes of, 993
Radioactive disintegration series, 986–987
Radioactive waste, 1003–1004
Radioactivity, 980–987, 994–998
  alpha radiation, 981–982
  beta radiation, 982–983
  gamma radiation, 983–985
  measuring, 994–998
  in nuclear equations, 982

  positron and neutron emission, 985–986
  radioactive disintegration series, 986–987
  X-rays and electron capture, 986
Radiological dating, 999–1000
Radionuclides, 980, 998–1000
Radio waves, 309, 311
Radon, 496, 1014–1015
Raoult, Francois Marie, 604
Raoult's law, 604–608
Rate, defined, 639
Rate constant (k):
  and activation energies, 672–673
  of first-order reactions, 656–657
  of second-order reactions, 662–663
  of zero-order reactions, 663
Rate-determining steps, 676, 678–680
Rate laws, 645–664
  and carbon-14 dating, 659–661
  and equilibrium laws, 701
  from experimental data, 648–653
  for first-order reactions, 654–659
  and graphs for orders of reactions, 663–664
  integrated, 654–664
  and orders of reaction, 646–648
  and reaction mechanisms, 676–680
  from reaction rates and concentrations, 645–646
  second-order rate constants, 662–663
  for second-order reactions, 661–663
  for zero-order reactions, 663
Rate-limiting (rate-determining) steps, 676, 678–680
Rate of evaporation, 541–542, 544, 545
Rate of reaction:
  defined, 641
  factors affecting, 637–639
  initial instantaneous, 643–644
  measuring, 639–644
  and rate laws, 645–646
  relative, 640–642
  for spontaneous changes, 874, 875, 897n.5
  and temperature, 636, 639, 672–673
Reactants:
  in chemical equilibrium, 697–698
  defined, 20
  in equilibrium, 710–711
  excess, 136
  limiting, 135–139
  and rate of reaction, 638–639
  of spontaneous electrochemical reactions, 932
Reacting fraction, in collision theory, 666
Reaction coordinate, of potential energy diagrams, 667
Reaction mechanisms, 675–680
Reaction quotient (Q). *See also* Ion product
  and free energy change, 900, 940
  and mass action expression, 699, 710, 832
Reaction rates, *see* Rate of reaction
Reactivity, electronegativity and, 381–382
Reactors, of nuclear power plants, 1002–1003
Real gases, 513–515
Reciprocal relationships, 748–750, 754
Red blood cells, 614, 616
Redox reactions, *see* Oxidation–reduction reactions
Red phosphorus, 460
Reducing agents, 214–215, 928
Reduction. *See also* Oxidation–reduction (redox) reactions
  of aldehydes and ketones, 1064
  defined, 214
  in galvanic half-cells, 925
  identifying, 220
Reduction potentials, 925–928, 956–958
Relative masses, of elements, 69–70
Relative rate of reaction, 640–642
Reliability, of measurements, 55–56
Rem (roentgen equivalent for man), 997
Replacement reactions, single, 231, 233–234
Replication, of DNA, 1086–1087
Representative elements, 74, 81, 86–87

ATOMIC MASSES OF THE ELEMENTS

This table is based on the 2007 table at *Pure Appl. Chem.*, **81**, 2131–2156 (2009) with changes to the values for lutetium, molybdenum, nickel, ytterbium and zinc from the 2005 table. Mass number of the longest-lived isotope of hassium from *Phys. Rev. Lett.*, **97** 242501 (2006). For the name of element 112 see *Pure Appl. Chem.* 2010, **82**, 753–755. http://www.chem.qmul.ac.uk/iupac/AtWt/. The number in parentheses following the atomic mass is the estimated uncertainty in the last digit.

At No	Symbol	Name	Atomic Mass	Notes
89	Ac	Actinium	[227]	5
13	Al	Aluminium	26.9815386(8)	
95	Am	Americium	[243]	5

92	U	Uranium	238.02891(3)	1, 3, 5
23	V	Vanadium	50.9415(1)	
54	Xe	Xenon	131.293(6)	1, 3
70	Yb	Ytterbium	173.054(5)	1
39	Y	Yttrium	88.90585(2)	
30	Zn	Zinc	65.38(2)	
40	Zr	Zirconium	91.224(2)	1

1. Geological specimens are known in which the element has an isotopic composition outside the limits for normal material. The difference between the atomic mass of the element in such specimens and that given in the Table may exceed the stated uncertainty.

2. Range in isotopic composition of normal terrestrial material prevents a more precise value being given; the tabulated value should be applicable to any normal material.

3. Modified isotopic compositions may be found in commercially available material because it has been subject to an undisclosed or inadvertant isotopic fractionation. Substantial deviations in atomic mass of the element from that given in the Table can occur.

4. Commercially available Li materials have atomic masses that range between 6.939 and 6.996; if a more accurate value is required, it must be determined for the specific material [range quoted for 1995 tables 6.94 and 6.99].

5. Element has no stable nuclides. The value enclosed in brackets, e.g. [209], indicates the mass number of the longest-lived isotope of the element. However three such elements (Th, Pa, and U) do have a characteristic terrestrial isotopic composition, and for these an atomic mass is tabulated.

The names and symbols for elements 113–118 are under review. The temporary system recommended by J Chatt, *Pure Appl. Chem.*, **51**, 381–384 (1979) is used above.

RELATIONSHIPS AMONG UNITS

(Values in boldface are exact.)

Length

1 in. = **2.54** cm
1 ft = **30.48** cm
1 yd = **0.9144** m
1 mi = **5280** ft
1 ft = **12** in.
1 yd = **36** in.

Volume

1 liq. oz = **29.57353** mL
1 qt = **946.352946** mL
1 gallon = **3.785411784** L
1 gallon = **4** qt = **8** pt
1 qt = **2** pt = **32** liq. oz

Mass

1 oz = **28.349523125** g
1 lb = **453.59237** g
1 lb = **16** oz

Pressure

1 atm = **760** torr
1 atm = **101,325** Pa
1 atm = 14.696 psi (lb/in.^{2})
1 atm = 29.921 in. Hg

Energy

1 cal = **4.184** J
1 ev = 1.6022×10^{-19} J
1 ev/molecule = 96.49 kJ/mol
1 ev/molecule = 23.06 kcal/mol
1 J = 1 kg m^{2} s^{-2} = 10^{7} erg

PHYSICAL CONSTANTS

Rest mass of electron	$m_e = 5.485799094 \times 10^{-4}$ u ($9.1093821 \times 10^{-28}$ g)
Rest mass of proton	$m_p = 1.0072764668$ u ($1.67262164 \times 10^{-24}$ g)
Rest mass of neutron	$m_n = 1.0086649160$ u ($1.67492721 \times 10^{-24}$ g)
Electronic charge	$e = 1.60217649 \times 10^{-19}$ C
Atomic mass unit	$u = 1.66053878 \times 10^{-24}$ g
Gas constant	$R = 0.0820575$ L atm mol^{-1} K^{-1} $= 8.31447$ J mol^{-1} K^{-1} $= 1.98721$ cal mol^{-1} K^{-1}
Molar volume, ideal gas	= 22.4140 L (at STP)
Avogadro's number	$= 6.0221418 \times 10^{23}$ things/mol
Speed of light in a vacuum	$c = 2.99792458 \times 10^{8}$ m s^{-1} (Exactly)
Planck's constant	$h = 6.6260690 \times 10^{-34}$ J s
Faraday constant	$F = 9.6485340 \times 10^{4}$ C mol^{-1}

LABORATORY REAGENTS

(Values are for the average concentrated reagents available commercially.)

Reagent	Percent (w/w)	$\frac{\text{Mole Solute}}{\text{Liter Solution}}$	$\frac{\text{Gram Solute}}{\text{100 mL Solution}}$
NH_3	29	15	26
